CHEMICAL ABSTRACTS

Vol. 20.

JANUARY 10, 1926

No. 1

1—APPARATUS AND PLANT EQUIPMENT.

W. L. BADGER

The technical spring fair at Leipzig, with heat and brown coal exhibits. BERTHOLD BLOCK. *Chem. App.* 12, 134-6, 142-4, 172-4, 185-6, 193-4, 202-4(1925); 33 cuts.—Descriptions of centrifugal and acid pumps, automatic chargers for phosphate furnaces, bisulfite furnaces, rotary filters, gas washers, a small O plant, feed-H₂O app., gages, etc.

Some new apparatus devised by Prof. R. Pohl, Göttingen. v. ÖLSHAUSEN. Z. *Elektrochem.* 31, 502-3(1925).—1. An experimental table. 2. Hydro-dynamic apparatus (a) for the detn. of current speed and pressure in relation to tube cross-section, and (b) a centrifuge for small-scale work, and detn. of particle size. 3. Wave-length apparatus with special shaft and carriage. No details of construction are given.

R. C.

Standardization of viscosity pipets. EMIL GARDOS. *Am. J. Pharm.* 97, 541-4(1925).—Results of expts. show that the present U. S. P. method for detg. the viscosity of liquid petrolatum is not sufficiently accurate, owing to the very conflicting results obtained by using pipets the specifications of which satisfy the demands in the U. S. P. In order to get the same results with different pipets, a standardization of the bulb and stem is needed, special attention being given to the delivery tube and to the bore.

W. G. GAESSLER

Calibration of the Vogel-Ossag viscometer. PASCHEN. Z. *angew. Chem.* 38, 891-2(1925).—Methods and fees of the Phys.-Techn. Reichsanstalt.

J. H. MOORE

A new type of nephelometer. R. KINGSLAKE. *Trans. Optical Soc. (London)* 26, 53-63(1924-5).—This describes a new type of nephelometer which enables measurement of minute amts. of ppt. by means of the turbidity it produces in soln. Light is passed into the end of a tube contg. the soln. and the intensity of the scattered light is measured by a special form of wedge photometer. Means by which stray light can be kept from the eye during observations is described.

D. E. SHARP

Turbidometer and colorimeter. H. DOLD. *Chem.-Ztg.* 49, 842(1925).—A description of a turbidometer sold by F. and M. Lautenschläger, Frankfurt a. M.

W. C. EBAUGH

A new laboratory stirring apparatus. ARNO MÜLLER. *Chem.-Ztg.* 49, 807(1925).—An illustrated description of a patented form of stirring app. marketed by A. Primavesi, Magdeburg.

W. C. EBAUGH

Grease-free mercury valve with porous glass plates. ALFRED STOCK. *Ber.* 58B, 2058-60(1925).—The previously described Hg float valve (cf. C. A. 9, 765; 11, 2637; 12, 547) has the disadvantage that it fails to function rapidly when large pressure differences exist across it. To overcome this disadvantage a Hg valve has been designed with porous glass plates to replace the glass float. The construction of this valve has been made possible by the recent development by the Jenaer Glaswerk Schott and Gen. of porous glass plates that can be fused into glass app. The plates permit passage of gas but are impervious to Hg. The permeability of gas varies between 100 and 500 cc. per min. per atm. drop. The valve consists of a glass U across the two arms of which are fused 2 porous glass plates. A T-connection at the bottom of the U leads to a Hg leveling device. When the Hg level is below the U, connection is made between the 2 arms of the U through the plates. To close the valve the Hg is run up against the 2 plates.

R. L. DODGE

An apparatus for approximate or comparative melting points of fats, waxes and petroleum. HOYT STEVENS. *J. Oil and Fat Ind.* 2, 28-30(1925).—A glass rod about the size of the thermometer is coated with a thin layer of the substance whose m. p. is to be detd. and suspended in the m. p. bath close but not touching the thermometer. The temp. at which the coating becomes transparent is the softening point and that at which it slides down the rod the m. p.

H. S. BAILEY

Welded steel pipe protected inside and out by reinforced concrete. A. BONNA. *Technique sanitaire* 20, 80-8(1925). J. J. HINMAN, JR.

Silica gel, its properties and apparatus for using it (HORST) 2.

Column still. J. SCHNEIBLE. U. S. 1,557,112, Oct. 13.

Filter. H. BECHHOLD. U. S. 1,557,234, Oct. 13. A filter adapted for purifying serums, H_2O , fruit juices or other liquids may be of diatomaceous earth which is impregnated with $AgCl$ or other insol. or difficultly sol. compd. of a metal of lower soln. tension than H and of higher soln. tension than Cu .

Filter. H. BECHHOLD. U. S. 1,557,235, Oct. 13. Filters for H_2O , fruit juices, serums, etc., and which may be formed of clay, C , diatomaceous earth, etc., are impregnated with substances at least one of which is a metal, e. g., Ag or Au , of lower soln. tension than H and of higher soln. tension than Pt , another being a compd. of a metal of lower soln. tension than H , e. g., $AgCl$.

Centrifugal filter. H. S. HELE-SHAW. U. S. 1,557,585, Oct. 20.

Rotary filter. W. D. MOUNT. U. S. 1,558,038, Oct. 20.

Air filter. A. JORDAHL. U. S. 1,560,790, Nov. 10.

Gas filter. R. M. RANYARD. U. S. 1,559,456, Oct. 27.

Filter for beverages, pharmaceutical solutions, etc. H. S. LEVINTHAL. U. S. 1,560,266, Nov. 3.

Filter for water, etc. W. L. HILBISH. U. S. 1,558,608, Oct. 27.

Filter for water, cider, beer, etc. W. L. COOP. U. S. 1,556,426, Oct. 6.

Viscometer. R. G. CASEY. U. S. 1,560,662, Nov. 10.

Viscometer. F. P. ZIMMERLI. U. S. 1,557,517, Oct. 13.

Optical pyrometer. F. H. SCHOFIELD. U. S. 1,560,864, Nov. 10.

Thermostat. G. H. WHITTINGHAM. U. S. 1,557,535, Oct. 13.

Temperature indicator and recorder. F. J. BAST and F. KRAMER. U. S. 1,551,129, Aug. 25.

Thermostatic temperature regulator. S. T. HINDENACH, J. G. BRADFORD, H. W. HUNTLEY and J. G. GOODHUE. U. S. 1,551,153, Aug. 25.

Liquid-oxygen container. C. MOTT and W. H. MARSHALL. U. S. 1,561,101, Nov. 10. U. S. 1,561,102 (C. Mott) also relates to a vacuum container adapted for transporting liquid air, etc.

Apparatus for charging liquids with carbon dioxide. G. F. SUGDEN. U. S. 1,561,036, Nov. 10.

Apparatus for contacting gases with liquids. P. M. KUEHN. U. S. 1,561,000, Nov. 10.

Apparatus for dehydrating air by refrigeration. J. A. MARTOCELLO. U. S. 1,558,741, Oct. 27.

Apparatus for disintegrating, emulsifying and mixing milk powder, china clay, barytes or other substances. H. POVEY and H. O. HALLAS. U. S. reissue 16,191, Oct. 27. (Original pat. No. 1,489,786, issued April 8, 1924; C. A. 18, 1768.)

Apparatus for continuous crystallization of sodium hyposulfite or other substances. H. HOWARD. U. S. 1,560,473, Nov. 3.

"Reflex oven" employing surface combustion. G. WOLLERS. U. S. 1,561,389, Nov. 10. An oven is specified, adapted for "hardening" (metals?) or producing low temp. tar, etc.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

The discipline of chemistry. C. H. DESCH. *Nature* 116, 504-5(1925).—A lecture. F. N. SCHOTT

Some Czech contributions to chemical science. J. G. F. DRUCE. *Science Progress* 20, 308-11(1925).—An essay on the present status of chemistry in Bohemia. JOSEPH S. HEPBURN

Chevreul. L. J. SIMON. *La nature* 53, ii, 235-8(1925).—A biography of Chevreul with portraits, with particular reference to his work on animal fats and org. acids and their classification, and his creation of proximate analysis. C. C. DAVIS

A new method of determination of certain dimensions of molecules and of the number N based on the study of the surface equilibrium of colloidal solutions. P. LE-

COMTE DU NOÛY. *J. phys. radium* 6, 145-53(1925).—By the use of the tension meter (cf. Noüy, *C. A.* 13, 1549, and Klopsteg, *C. A.* 18, 3501) the adsorption isotherms of different colloidal sols. have been detd. as a function of time. These colloids were studied: proteins (albumin, globulin, hemoglobin, etc.), oleates, stearates taurocholates, Na glycocholate, saponin, etc., a large no. of coloring materials and electrosols of Au, Ag, Fe and Al. The fall of the surface tension was from the beginning and during a time which depended on the concn. proportional to the time and then followed a logarithmic law as a function of time. In the case of Na oleate at the concn. of 10^{-8} this proportionality continued to the equilibrium value of 32 dynes at 22° . No explanation is offered for the observation that during the 1st 10 mins. (approx.) with Na oleate at concns. between 1×10^{-8} and 4×10^{-8} one-third the time is required to produce the same lowering of surface tension if the concn. is doubled. When the sols. were shaken or agitated, even slightly, the surface tension rose, but not to the initial value except for some very dil. sols., and then decreased according to the same law as above. This phenomenon could be repeated indefinitely. In order to obviate the effect of agitation and to det. the min. value of surface tension at the end of an arbitrary time, the sols. were placed side by side on a table supported on piers. The tension meter was brought successively to the sols. on a little carriage rolling on rails. For each substance a max. fall occurred at a certain concn. (e. g., $1/140,000$ for egg albumin). This max. corresponded to a critical arrangement of the mols. and was evidently a function of the ratio (adsorption surface) (S)/ (vol. of the liquid) (V). By adding glass spheres of known surface, expts. demonstrated that the displacement of the max. was directly proportional to the different values of S/V , i. e., adsorption occurred on the glass as well as on the surface of the liquid. In the curves plotting surface tension at the end of 2 hrs. with concn., 3 well-defined minima occurred. These min. were attributed to a geometrical arrangement of a mono-mol. layer of mols. oriented in parallel (polarized) on the surface. By assuming that all the mols. were adsorbed and using the vol. and concn. of the soln., the total area of surface and the d. of pure Na oleate, the thickness of the adsorbed layer for the 3 min. at concns. of $1/750,000$, $1/1,220,000$ and $1/1,390,000$ corresponded, resp., to 12.3×10^{-8} , 7.56×10^{-8} and 6.64×10^{-8} cm.. By considering the 3 thicknesses to correspond to the 3 dimensions of a mol. of Na oleate and using the d. and mol. wt. of pure Na oleate, $N = 6.004 \times 10^{23}$. A discussion of the sources of error indicated an accuracy of 0.15%, i. e., $N = 6.004 \pm 0.09 \times 10^{23}$.
H. M. McLAUGHLIN

The derivation of the equation for the effect of temperature on reaction rate. R. C. TOLMAN. *J. Am. Chem. Soc.* 47, 2652-61(1925).—The equation of Arrhenius for the temp. coeff. of mono- and bi-molecular reaction is derived on the assumptions of microscopic reversibility, i. e., that the condition of statistical equil. is that the number and rate of the mols. entering any statistical state shall be equal, and on the assumption that the number of unactivated mols. is given by the Maxwell law. No assumption of the mol. mechanism or indeed of the mol. significance of the process of activation need be made. The energy of activation comes out a function of the difference of the av. energies of the activated and non-activated mols. and not as a function of the difference of the individual energies as assumed by Lewis and Smith in their account of the mechanism of activation. This mechanism must therefore be wrong. No alternate mechanism is offered here.
F. R. B.

Cohesive forces of liquids. A. TH. VAN URK. *Proc. Acad. Sci. Amsterdam* 28, 356-64(1925).—See *C. A.* 19, 3185.
E. J. C.

Equilibrium in the system zinc sulfate-water. ERNEST COHEN AND A. L. TH. MOESVELD. *Proc. Acad. Sci. Amsterdam* 28, 461-6(1925).—See *C. A.* 19, 2158.
E. J. C.

Study of the ternary mixture—water, ethyl alcohol, normal butyl alcohol. F. DROUILON. *J. chim. phys.* 22, 149-68(1925).—The temps. of mutual soly. of the two phases formed by mixing different portions of H_2O , EtOH and BuOH were detd. by sealing a number of known mixts. in small glass tubes and heating slowly until the boundary between the phases disappeared. From these data curves were drawn representing the soly. of BuOH in a series of EtOH- H_2O mixts. (from 0 to 25% EtOH by wt.) covering a temp. range from 10° to 130° . The data are also shown in triangular coordinates. The coeff. of partition of BuOH between the aq. and alcoholic layer at 20° was then detd. over a wide range of concn. The method of analysis of the phases was based on the addn. of a known wt. of either EtOH or H_2O and detn. of the temp. of mutual soly. as in the case of the first expts. The coeffs. thus detd. varied from 12.3 to 1.00.
A. W. KENNEY

Standardization and calculation of results for the Haber-Löwe gas interferometer. G. WERNER. *Z. angew. Chem.* 38, 905-11(1925).—Equations and tables are given

for the standardization and for the use of this app. in the detn. of the compn. of binary gas mixts. The use is discussed in detail and a bibliography given. WM. B. PLUMMER

A general theory of solvent systems. A. F. O. GERMANN. *J. Am. Chem. Soc.* **44**, 2461-8(1925).—Based on a study of the analogy between the reactions in H_2O and in $COCl_2$ solns., a general theory of acids, bases and salts as related to a parent solvent has been outlined. The common definitions of aquo acids, aquo bases and aquo salts or ammono acids, ammono bases and ammono salts have been generalized to include other solvents and the names changed to *solvo acids*, *solvo bases* and *solvo salts*. The application of the theory to other solvents— SO_2Cl_2 , $SeOCl_2$ and $SOCl_2$ —has been suggested. H. M. McLAUGHLIN

Considerations on the properties of physical systems in the vicinity of the critical state. L. ÇAY AND N. PERRAKIS. *J. chim. phys.* **22**, 169-85(1925).—A general consideration is given to the phenomena of the crit. point. By definition, any system containing any number of phases, of which at least two are fluid, is at the crit. point with regard to these two fluid phases when by causing a suitable variation in the conditions imposed on this system the two phases in question mix and become identical at all points. Illustrations as, for example, C_2H_4 -EtOH mixts. and nicotine- H_2O mixts. are given. The major portion of the article is devoted to theoretical generalizations in regard to the analytical geometry of crit. points and the mathematical form which the different curves may take. By a suitable choice of variables the crit. curve may be represented by an approx. straight line. A. W. KENNEY

Colloidal cobaltic hydroxide. C. PAAL AND HANS BOETERS. *Ber.* **58**, 1539-41 (1925).—*Prepn.*: (a) Oxidation with air. A soln. of 1 g. of Na protalbinat or lysalbinat in 25 cc. of H_2O was treated alternately with small portions of $CoCl_2$ (1%) and NaOH (normal) until a permanent turbidity (after about 9-10 cc. of the $CoCl_2$) remained. The hydrosol was dialyzed for 3-4 days until free of Cl^- . After 1 day the cobaltous was changed to cobaltic hydrosol by the O_2 of the air. With transmitted light the content of the dialyzer changed from a deep green to a reddish brown. After filtering the hydrosol was concd. by evapg. at 50-60° and 25 mm. pressure and finally dried in a vacuum desiccator. (b) Oxidation with H_2O_2 . The procedure was the same as in a except that 2 g. of the Na protalbinat or lysalbinat was dissolved in 20 cc. H_2O and 10 cc. of 3% H_2O_2 added before adding the $CoCl_2$ and NaOH. Brittle, black lustrous lamella easily sol. in H_2O were obtained. H. M. McLAUGHLIN

The densities of beryllium halides. CARL MESSERKNECHT AND WILHELM BILTZ. *Z. anorg. allgem. Chem.* **48**, 152-6(1925).—The densities of beryllium chloride (I), bromide (II) and iodide (III) were detd. by means of a pycnometer. Mineral oil b. 180-240° was used. I and II were prepd. by the action of the respective halogens on BeO in the presence of C. All three were obtained also from the beryllium carbide and purified by sublimation. The mol. vols. calcd. from the d agree with those calcd. from the mol. vols. of K halides according to the equation $V_{BeHal_2} = aV_{KHal_2} + b$, where $b = -2.76$, $a = 1.193$. No simple relation to Biltz's extension of Kopp's rule could be found. EMIL KLARMANN

Specific gravity of concentrated solutions of orthophosphoric acid. WM. H. ROSS AND R. M. JONES. *Ind. Eng. Chem.* **17**, 1170-1(1925).—The sp. gr. of solns. of H_3PO_4 of 90 to 100% concn. was detd. at different temps. ranging between 20° and 60°. W. H. ROSS

Silica gel, its properties and apparatus for using it. F. W. HORST. *Chem. App.* **12**, 159-61, 201-2(1925); 7 cuts. J. H. MOORE

The kinetics of sol-gel-transformation of concentrated ferric oxide sols. H. FREUNDLICH AND A. ROSENTHAL. *Kolloid-Z.* **37**, 129-31(1925); cf. Schalek and Szegvary, *C. A.* **17**, 2663.—The observed and calcd. (cf. *C. A.* **14**, 1067) velocity of gelation (reciprocal of the time required for the sol-to-gel transformation) were in close agreement. With increasing electrolyte concn. the velocity of gelation increased to a const. value which was then independent of the concn. of the electrolyte. During the measurements it was necessary to retard the gelation by adding glycooll, alanine and similar compds. (cf. Paine and Evans, *C. A.* **18**, 609). These added substances were not characteristically protective but seemed to form inner complexes with the Fe on the surface of the colloid particle. H. M. McLAUGHLIN

Monomolecular soap films in emulsions. WM. RIEMAN 3RD AND P. A. VAN DER MEULEN. *J. Am. Chem. Soc.* **44**, 2507-13(1925); cf. *C. A.* **18**, 1412.—Emulsions of the oil-in- H_2O type contg. a soln. of C_6H_5OH in toluene as the internal phase and Na oleate as the emulsifying agent have been studied. When the concd. emulsion was dild. 5 to 500 cc. instead of 10 to 500 cc. the av. area of interface covered per mol. varied, i. e., the av. area per mol. depended primarily on the concn. of the soap in the external

phase and not on the concn. of the soap in the concd. emulsion. The C_6H_5OH displaced the soap in the film to a limited extent and affected the av. area per mol. of soap. When the soap concn. in the external phase of the dil. emulsion exceeded 0.01 M, the protective film was composed of closely packed, oriented soap mols., occupying an av. area of 17 sq. Å. each. To account for the difference from the area of 22 sq. Å. per $-COOH$ found by Langmuir (cf. *C. A.* 11, 2849) and others, it is assumed that the neighboring $-COOH$ groups are drawn into the H_2O to different depths and that the 17 sq. Å. represents the av. cross-sectional area of the hydrocarbon chain of the oleic acid.

H. M. McLAUGHLIN

The absorption of oxygen and liberation of carbon monoxide by alkaline pyrogallol solutions. T. J. DRAKELEY AND HUGH NICOL. *J. Soc. Chem. Ind.* 44, 457-62T (1925).—Preliminary investigation showed that all of the alk. pyrogallol solns. described in the literature yielded CO when absorbing O of high strength. Systematic study of the absorption conditions showed that the CO production was minimized under the following conditions: use of a highly concd. absorbent soln., vigorous agitation of the absorbent, use of a nearly fresh pyrogallol soln., and diln. of high concn. O to not over 25% with N. No difference in CO production was noted when KOH, NaOH, or NH_4OH was used as alkali. The Orsat app. is unsuitable because agitation of the absorbent is difficult. The best general soln. is that of Anderson, contg. 15 g. of pyrogallol to 100 cc. KOH, d. 1.55. For accurate O detn., a separate CO detn. should be made after the O detn.

T. S. CARSWELL

Adsorption of acids by purified silica. J. N. MUKHERJEE. *Nature* 115, 497 (1925).—M. showed in *C. A.* 19, 1320, that hydrated silica free from all impurities adsorbs acids. Data are now given to show that thoroughly washed hydrated silica, prepd. from pure $SiCl_4$ and allowed to be partially dehydrated in air at room temp., exhibits a marked increase in its capacity to adsorb acids.

FLORENCE N. SCHOTT

Catalytic transference of hydrogen as the basis of the chemistry of dissimilation processes. A. J. KLUYVER AND H. J. L. DONKER. *Proc. Acad. Sci. Amsterdam* 28, 605-18 (1925).—See *C. A.* 19, 2354.

E. J. C.

Comparative investigations of the activity of contact catalysts. II. Water synthesis by metals of the iron group and by binary alloys that these metals form with the platinum group metals, insofar as they are catalytically active at room temperature. H. REMY AND H. GONNINGEN. *Z. anorg. allgem. Chem.* 148, 279-92 (1925); cf. *C. A.* 18, 3307.—The comparative catalytic activity of Rh, Pd, Os, Ir, Pt toward the reaction $2H_2 + O_2 = 2H_2O$ was redetd. in a new app. by the same method as in the previous investigation. The results of the previous investigation were confirmed in every case. The influence on the catalytic activity of preliminary treatment of the catalyst with H or O was detd. as well as the influence of H, O or N as diluent in the electrolytic gas mixt. The metals and alloys were prepd. by the same method as previously described. The pure metals of the Fe group that were studied were Fe, Co and Ni; the alloys (proportions not given) were Rh/Fe, Rh/Ni, Pd/Fe, Pd/Co, Pd/Ni, Ir/Fe, Ir/Co, Ir/Ni, Pt/Fe, Pt/Co, Pt/Ni. In general the catalytic activity of the alloys was found to be less than for the corresponding Pt group metals under the same conditions. After preliminary treatment with H the Ni alloys were the most active of the alloys, but after O treatment they were decidedly the least active. The Fe alloys showed the reverse behavior, being least active after preliminary H treatment, and particularly active after O treatment. The metals and alloys that do not catalyze the synthesis of H_2O at room temp. under any conditions are Fe, Co/Fe, Ni/Fe, Ru/Fe, Os/Fe, Co, Ni/Co, Ru/Co, Os/Co, Rh/Co, Ni, Ru/Ni, Os/Ni, Ru. The alloys Rh/Fe and Ir/Fe will catalyze the reaction at room temp. only after preliminary treatment with H; Rh/Ni only after preliminary treatment with O. Os, Os/Ru, Rh, Rh/Os, Rh/Ru, Ir, Ir/Rh, Ir/Os, Ir/Ru, Ir/Ni, Ir/Co, Pd, Pd/Ir, Pd/Rh, Pd/Os, Pd/Ru, Pd/Ni, Pd/Co, Pd/Fe, Pt, Pt/Pd, Pt/Ir, Pt/Rh, Pt/Os, Pt/Ru, Pt/Ni, Pt/Co, Pt/Fe all catalyze the reaction at room temp.

R. L. DODGE

Heterogeneous catalysis. J. R. PARTINGTON. *Nature* 115, 534 (1925).—Graham's explanation for the adsorption of H by Pt is quoted.

F. N. SCHOTT

Gaseous catalysis by metals of the platinum group. L. DUPARC, P. WENGER AND CH. URFER. *Helvetica Chim. Acta* 8, 809-31 (1925).—The catalytic action of Rh was measured in two types of gaseous reactions. The first type was oxidation reactions, the second reduction reactions. The Rh was employed in the form of "Rh Black" deposited on asbestos fibers for support. In several expts. the action of the Rh catalyst was compared with the action of Pt black under similar conditions. The oxidation reactions investigated were the oxidation by O of (1) SO_2 and (2) NH_3 . The reduction reactions were the reduction by H of (1) CO, (2) CO_2 , (3) NO and (4) N_2O . The dy-

namic method was used. The catalytic oxidation of SO_2 is claimed to proceed through the formation of intermediate compds. of the O with the catalyst. In the oxidation of NH_3 the Rh catalyst was found to be more active than the Pt catalyst. This reaction is claimed to proceed through the formation of a hydride of Rh and nascent N. By suitable choice of conditions (not specifically indicated) the reduction of CO by H could be made to proceed completely to CH_4 without the formation of C. The reduction of CO_2 to CH_4 proceeded less easily. NO was reduced to NH_3 , while the product of reduction of N_2O was invariably N_2 . This fact is used to support the theory that all reactions of N proceed only through the nascent state. R. L. DODGE

Thermodynamics of the quinhydrone electrode and the chemical constant of hydrogen. ERLING SCHREINER. *Z. physik. Chem.* 117, 57-87(1925).—The sp. heat of quinone, hydroquinone and quinhydrone were measured from 10° to 300° . The heat of combustion of these substances was measured and found to be at const. vol. (wts. reduced to vacuum), resp.: 656.61, 682.29 and 1334.54 kcal. per mol. The heat of solution of quinone in water was -43.4 cal./g.; in 50% AcOH $+42.55$ cal./g. The heat of soln. of hydroquinone was $+40.9$ cal./g.; in 50% AcOH $+31.1$ cal./g. The solubilities of hydroquinone and of quinone were measured in water and in H_2SO_4 solus. The e. m. fs. of the cells Pt|hydroquinone, quinone, H_2SO_4 | H_2 |Pt, and the similar cells with hydroquinone, quinhydrone and with quinone, quinhydrone, as well as their temp. coeffs. were measured. All of these data are consistent with the second and third laws of thermodynamics and lead to the values for the chem. const. of H of 1.11, 1.12, 1.11, 1.09 and 1.01, of which the last value has little wt. F. R. B.

The measurement of very low temperatures. XXXIII. Comparison of the hydrogen and the helium thermometers of constant volume at different zero-point pressures. F. P. G. A. J. VAN AGT AND H. KAMERLINGH ONNES. *Verslag. Akad. Wetenschappen Amsterdam* 34, 644-51(1925).—The results of previous papers are used for comparison of the Celsius-Avogadro temp. scales (based on $\alpha = 0.0036618$) of the He and the H_2 thermometers. It appears from the linear $(t_{\text{He}} - t_{\text{H}_2})/p_0$ curves for different temps, that the differences converge all to zero at $p_0 = 0$. The accuracy of the temp. scale used with the given corrections is about 0.002° down to 14° K. B. J. C. VAN DER H.

A buffer method for calorimetry at high temperatures. W. A. ROTH. *Z. Elektrochem.* 31, 456(1925).—In order to damp the sudden flux of temp. produced by dropping a hot body into a calorimeter it is proposed to catch the body in a bed of some easily fused salt, thus preventing temp. rises to a point higher than the m. p. of the salt. F. R. B.

Thermal expansion of crystals and chemical composition. F. A. HENGLEIN. *Z. Elektrochem.* 31, 424-8(1925).—The density of the alkali halides as measured in a gas-filled pycnometer at 0° , -79° and -184° arc, resp.: LiF 2.642, 2.6606, 2.6780; LiCl 2.0712, 2.0913, 2.1135; LiBr 3.4207, 3.4589, 3.5022; LiI 3.9261, 3.9781, 4.0375; NaF 2.8043, 2.8273, 2.8471; NaCl 2.1677, 2.1866, 2.2080; NaBr 3.2139, 3.2445, 3.2814; NaI 3.6587, 3.6982, 3.7466; KF 2.5202, 2.5428, 2.5638; KCl 1.9925, 2.0086, 2.0277; KBr 2.7557, 2.7799, 2.8096; KI 3.1265, 3.1577, 3.1968; RbCl 2.7302, 2.7516, 2.7783; RbBr 3.2805, 3.3074, 3.3419; RbI 3.5148, 3.5481, 3.5901. The coeff. of expansion is inversely proportional to the heat of formation for all these salts. The connection between coeff. of expansion and the possibility of forming mixed crystals is discussed in a general way. F. R. BICHOWSKY

Sweet ice from sea water. Last reply to J. J. Van Laar. CH. M. VAN DEVENTER. *Chem. Weekblad* 22, 475(1925); cf. C. A. 19, 2438, 2439, 3410. MARY JACOBSEN

Distribution of electrons in atoms. J. D. M. SMITH. *Phil. Mag.* **50**, 878-9(1925).
—A priority claim. S. C. L.

Professor Whittaker's atomic model. J. A. ELDRIDGE. *Proc. Roy. Soc. Edinburgh* **45**, 245-8(1924-5); cf. *C. A.* **16**, 3428-9.—W. has failed to take into account the forces on the central pole of his magnetic wheel, which will not in fact be set into rotation on the approach of the electron as he assumes. He has in effect employed a unipolar magnet—"a conception abhorrent to physics."—In a note W. says in reply that the essential feature of his model is the *magnetic current* which is a new conception not derivable from old conceptions. The storage of momentum in the ether involved in the model is a generally accepted conception. In a second note H. STANLEY ALLEN says: "There is a way out of the difficulty if we suppose that the electron, instead of moving along the axis of the 'wheel,' passes through the ring of poles of one name but not through the ring of poles of contrary name." NORRIS F. HALL

The fields of force of polarized dielectrics. AMALIA CALDI. *Nuovo cimento N. S.* **2**, No. 2, 125-42(1925).—C. has deduced a formula based upon theoretical considerations which permits the calcn. of dilatation per unit vol. of spherical condensers. The calcd. values obtained by C. are much nearer the exptl. values obtained by Quincke than Quincke's calcd. values are. L. T. FAIRHALL

Equilibrium between matter and radiation. OTTO STERN. *Z. Elektrochem.* **31**, 448-9(1925).—Recent exptl. studies of the equivalence of mass and energy, as given by the special relativity formula $E = mc^2$, suggest that these 2 quantities are interconvertible. Thermodynamics is therefore applicable to reversible transformations of matter and energy. An expression is developed, by use of Nernst's heat theorem, for the entropy change involved. From this it is possible to calc. the number of atoms in equil. with black-body radiation at any temp. Eddington's deductions for the loss of wt. of stars due to energy radiation are verified qual. For an electron d. as small as 1 electron per cm.³: a temp. of 100,000,000°C. is necessary, and for H nuclei the temp. must be at least 2000 times as high. This fact explains the extraordinary preponderance of electrons over protons in the material world. HARRY R. MOORE

The derivation of Planck's law from Einstein's equation. A. S. EDDINGTON. *Phil. Mag.* **50**, 803-8(1925).—A direct derivation is given of Planck's radiation law from Einstein's equation (*C. A.* **11**, 729), without assuming Boltzmann's formula. S. C. L.

Atomic structure and coördination number. J. D. MAIN SMITH. *Chemistry and Industry* **44**, 944-7(1925); cf. *C. A.* **18**, 1944.—A brief restatement and discussion of the so-called "Stoner" scheme of allotting electrons to quantum sub-groups (first published by Smith, l. c.). The author concludes: (1) In any two-electron link both electrons must belong to the same quantum sub-group (in opposition to Sidgwick's view (*C. A.* **18**, 196)). (2) In many cases the two-electron link is inadmissible. (3) The max. coördination no. is unrelated to the size of any quantum group or sub-group in any atom. (4) "No means other than expt. exist... for detg. the no. of electrons in any chem. bond." (5) "The time is not yet ripe for the application of general electronic theories of chem. combination either in org. or inorg. chemistry." NORRIS F. HALL

The isotope effect in band spectra. IV. The spectrum of silicon nitride. R. S. MULLIKEN. *Phys. Rev.* **26**, 319-38(1925); cf. *C. A.* **19**, 3060.—The spectrum of the bands obtained by passing SiCl₄ vapor into active N₂ was rephotographed, and the quantum relations were applied. The vibrational quantum effect was confirmed for Si²⁹ and Si³⁰. The evidence is against half quantum nos. for SiN. D. C. BARDWELL

The separation of chlorine into isotopes (isotopic elements) and the whole-number rule for atomic weights. W. D. HARKINS. *Proc. Nat. Acad. Sci.* **11**, 624-8(1925).—A review of the work of sepg. Cl into isotopes. Samples with at. wts. 0.055 units higher and 0.04 units lower than ordinary Cl have been obtained. MARIE FARNSWORTH

The isotopic composition of the element chlorine in meteorites: the atomic weight of meteoric and terrestrial chlorine. W. D. HARKINS and S. B. STONE. *Proc. Nat. Acad. Sci.* **11**, 643-5(1925).—Cl from a meteorite and from a rock of non-marine origin (wernerite) has exactly the same at. wt. as ordinary Cl. The bearing of these results on the history of the earth and the meteorites and the stability of the atoms of the two isotopes are discussed. MARIE FARNSWORTH

The radioactivity of potassium, rubidium and other elements. W. D. HARKINS and W. G. GUY. *Proc. Nat. Acad. Sci.* **11**, 628-30(1925).—The method used to measure the radioactivity is to balance the natural leak of a large ionization chamber against another one containing U₃O₈. The radiation from Rb salts is 10-15 times weaker than that from K and is probably more complex. MARIE FARNSWORTH

Electric phenomena in the atmosphere. J. CLAY. *Proc. Acad. Sci. Amsterdam*

28, 531-5(1925).—On the plateau of Bandoeng the potential gradient has a mean value of about 90 v., a max. value of 250 v. and a min. value of 40 v. per m. It is higher at greater elevations. The mean no. of positive ions found per cc. was 260 and the no. of negative ions 220. The value for Rn was 3×10^{-10} curie per cc. M. F.

Ionium. I. Recovery of ionium from carnotite. II. Adsorption of ionium-thorium by barium sulfate. III. Ionium-thorium ratio in carnotite. G. D. KAMMER AND ALEXANDER SILVERMAN. *J. Am. Chem. Soc.* **47**, 2514-22(1925).—There is no good method for sepg. Io directly from carnotite. That carried down with the Ra-Ba sulfate can be sepd. by fusion by Na_2CO_3 or boiling with Na_2CO_3 . BaSO_4 has an extraordinary capacity for the adsorption of Th, 1 g. of BaSO_4 adsorbing as much as 16% of its own wt. of ThSO_4 . The Io-Th ratio in av. Colorado carnotite is 1:15.8.

MARIE FARNSWORTH

Proof of the existence of retrograde hydrogen particles from disintegrated atoms. GERHARD KIRSCH. *Physik. Z.* **26**, 379-80(1925).—Rutherford and Chadwick have contended (*C. A.* **16**, 526, 4128) that H particles ejected at angles of 90° - 180° to the direction of α -rays hitting the nuclei of B, N, F, Na, Al, P atoms are true retrograde rays. A re-investigation of these data has lead K. to the conclusion that the observed backward ranges are those of particles sent off at right angles to the various directions of incidence of the colliding α -rays. Therefore R. and C. have not proved the existence of retrograde H particles, but this has been accomplished in Vienna by means of special methods.

H. R. MOORE

The reflection of α -particles from atomic nuclei. HANS PETTERSSON. *Arkiv for Matematik, Astronomi och Fysik* **19A**, No. 15(1925) (in English).—The numbers of α -particles and of H-particles reflected per min. from collisions between α -particles from Ra C and at. nuclei of Mg, Al, Cu and Ni, and following paths 150° from the initial paths of the α -particles have been counted with the aid of a microscope of new design which secures greater apparent brilliancy for the impacts on a ZnS screen. Mica screens were used to det. the residual air-absorption ranges of the particles. The α -particles could be distinguished from the H-particles by the greater brilliancy of their scintillations. The very few α -particles reflected from C and Mg and their low ranges suggest that the collisions with atomic nuclei are not elastic impacts. Ni and Cu reflect numerous α -particles at 150° but their max. residual ranges are too low for elastic collision (*i. e.*, for Ni 3.4 cm. air instead of 4.6; for Cu 3.0 instead of 4.5). C. M. B.

The aging effect in the mobility of positive ions. H. B. WAHLIN. *Proc. Nat. Acad. Sci.* **11**, 606-8(1925).—W. answers Loeb's criticism (cf. *C. A.* **19**, 3214) of the results on the effect of aging on the mobility of positive ions. The change in mobility observed by Loeb was due to the gauze and was absent in W.'s results.

MARIE FARNSWORTH

Glow discharge in high-frequency fields. FRITZ KIRCHNER. *Ann. Physik* **77**, 287-301(1925).—In specially constructed double tubes, one side being used for the glow discharge, the other side (evacuated) for cathode-ray production, with two electrodes in common, the min. potential necessary for the glow discharge was measured from the max. deviation of a pencil of electrons, which crossed the field of the electrodes. The behavior of air, Ne, H_2 and O_2 was investigated. It was found that on applying potentials, obtained from a wireless transmitter tube, with frequencies of 1.2 to 3.5×10^7 , the min. potential required to run the discharge fell down considerably, for Ne a min. potential of 15 v. was observed. At const. frequency the potential decreases slightly with diminishing pressure, passes a min. at about 0.4 mm. and then increases rapidly. The min. for $n = 3.5 \times 10^7$ in air lay at 28 v., 0.4 mm Hg, *i. e.*, $1/10$ of the d. c. min. potential. Expts. on the influence of varying electrode distance showed that the potential minima become sharper and occur at lower pressures the larger the electrode distance. K. explains these phenomena by assuming that as a result of the high frequency of the current, the electrons swing back and forth in the gas, ionize repeatedly, liberating new electrons, without ever reaching the electrodes; no high cathode fall is in this case necessary to keep up the electron production. The mean free path, *i. e.*, the chance for an electron to collect sufficient energy for ionization, is longer the lower the gas pressure; consequently the discharge potential drops for decreasing pressures; as soon, however, as the free path becomes of the order of the electrode distance further pressure decrease results in an increasing potential. The electrode distance in other words measures the m. f. p. (between two nonelastic collisions) of the electrons at the pressure corresponding to the potential min. On reducing the m. f. p. values to 760 mm. they are found to check satisfactorily and to be 3 to 5 times as large as those derived from the gas kinetic laws.

B. J. C. VAN DER HOEVEN

Magnetic field of a moving electron. F. COUÉRY. *Compt. rend.* **179**, 895-7(1924).

—The application of Maxwell's theory leads to a value for the magnetic field of a moving electron which is not in accordance with the first law of Laplace. There results from this expression an action between elements of current which is half that observed, but it is not an admissible hypothesis to attribute half the action to modifications of the elec. field due to the movement. Conclusion: the magnetic field of an electron is a mathematical expression without physical reality. B. C. A.

Electrical discharge in gases at low pressures. R. MAGINI. *Nuovo cimento* N. S. 2, No. 2, 83-124(1925).—The exptl. results obtained by M. demonstrate the complete efficacy of a photographic means of following the course of cathode rays. This permits a discrimination of the elements of discharge not accessible by other means. Through the superficial limits of the cathode and the intensity of flow electrodes become rapidly coated in the air with a skin and the photograph indicates an anomalous form of discharge. With a cathode centered in a large balloon the positive flow is uniform and the limit of dark space is a function of the anode; the ions move freely and the discharge is symmetrical. In cylindrical tubes the appearance of the discharge is altered owing to the action of the walls. With a given aperture there is established an axis of discharge with opposed cathodic bundles and bands. The flow and current are at a max. in the direction of the cathode axis. Mica placed before the cathode resulted in a modification of flow, but the discharge tended to preserve its original symmetry. It is possible that the true cathode is constituted of the stratum of gas directly in front of the metal cathode. L. T. FAIRHALL

Demonstration of the photoelectric effect with the glow lamp. H. GREINACHER. *Physik. Z.* 26, 376-9(1925).—Expts. are described which are similar in many respects to those of Oschwald and Tarrant (*C. A.* 18, 3008) on the effect of external light sources on the p. ds. necessary to maintain a glow discharge. G. finds that the luminous discharge occurs at the usual voltage when p. ds. somewhat less than the discharge p. d. are first applied, and the tube is then irradiated with light from a Zeiss arc. The effect is tested with 6 types of glow lamps under variable voltages and different electrodes in the tubes. This reduction of the p. d. necessary for discharge is probably due to a simple photoelec. effect, since the negative electrode must be exposed in every case. Moreover, the magnitude of the effect bears a definite relation to the intensity of the light. In general, the light intensity must be higher the greater the difference between the impressed potential and the glow potential. H. R. MOORE

Electronic conduction in crystals. H. LENZ. *Physik. Z.* 26, 481-3(1925).—Acting on the assumption that electron conductance in crystals may be increased by the introduction of free electrons into the crystal, L. has designed an app. for bombarding ZnS crystals with cathode rays. The crystal face exposed to the rays is covered with a thin layer of Ag, which serves to conduct excess electrons to earth. One terminal of a sensitive galvanometer is connected to the posterior side of the crystal and the other in series with a high potential battery. Although only a small fraction of the bombarding electrons penetrates the crystal, the cond. is found to be 10^{-8} amp. or 10,000 times the usual primary photoelec. current. Destruction of the ZnS lattice is thus accompanied by a strong "electrolytic current" in the crystal. No systematic study is made of the dependence of this new effect on crystal thickness, voltage and cathode-tube voltage. Concomitant studies of the variance of the photoelec. conductance of diamond and ZnS crystals with temp. are readily interpreted in light of the new effect. The curves obtained affirm L.'s theory that the primary photoelec. current is due to displacement of electrons within the crystal lattice. Photoelec. conductance is a rapidly increasing function of temp., since thermal excitation undoubtedly increases the effective number of cond. electrons. HOWARD R. MOORE

Ionization and activation potentials. I. Methods of determining critical potentials. K. T. COMPTON. *Fortschritte Chem.* 18, 291-351(1925).—A large no. of methods for detg. crit. potentials are critically discussed, together with methods for distinguishing between crit. potentials of atoms and mols. A no. of problems are suggested for further work; e. g., degree of activation, intensity of spectral lines, mean free path of electrons, etc. Finally a no. of suggestions as to general technic are given. **II. Critical potentials and their significance.** F. L. MOHLER. *Ibid* 352-425.—The work which has been done on simple ionization and resonance potentials of the atoms is discussed, taking them up as they occur in the periodic system, and the results are compared with values calcd. from spectral data. The significance of higher crit. potentials is pointed out and values obtained for double ionization, ionization of ions, combined ionization and excitation, excitation of ions, etc., are discussed. Crit. potentials of mols. and the potentials for the production of X-ray spectra are treated. A bibliography of 180 references is given. A. E. S.

The attachment of electrons to gas molecules. V. A. BAILEY. *Phil. Mag.* 50, 825-43(1925).—For N collisions between electrons and gas mols. let h be the fraction that results in attachment. B. asserts that h is not independent of u , the velocity of agitation of the electrons, and criticizes the results of others involving the assumption of independence of h and u . B. develops a new method to test the relation which depends on causing photoelectrons and the ions resulting from attachment to move under a uniform field through a series of plates with central circular openings, which serve to filter out that part of the electrons and ions that has diverged from the line of flow. Since the electrons diverge more than the ions, each plate increases the ratio of the latter to the former, and this effect is still further enhanced by recombination with positive ions. The theory is presented in detail and the equations are deduced necessary to its test by employing the exptl. data obtained. For thoroughly dry air the following results were calcd.

Z/p	0.5	1.0	2.0
h	3.3×10^{-8}	2×10^{-8}	0.7×10^{-8}
	3.3×10^{-7}	4.5×10^{-7}	6×10^{-7}

showing how rapidly h diminishes with increasing u . (Z/p is the ratio of voltage drop to pressure.) Without a more accurate knowledge of the mean free path of electrons in O_2 , one can only estimate from these results that h for O_2 is of the order 10^{-8} , admitting h for N_2 to be infinity. In other words, about 1 collision in 100,000 results in attachment of a free electron to form a negative O_2 ion. S. C. LIND

Impact experiments in compound gases. Ammonia. ALMA T. WALDIE. *J. Franklin Inst.* 200, 507-18(1925).—Photoelectrons obtained by irradiating Ni on acceleration gave crit. potentials at 11 v. (confirming Mackay, *C. A.* 18, 352), at 22 and perhaps at 33 v. On continuing the expt. crit. voltages for H and N were obtained. Thermions on colliding near the wire give values chiefly for H with some N due to thermal decompn. of NH_3 . Farther away from the wire a few impacts were obtained with NH_3 . F. O. A.

The ionization of HCl by electron impacts. E. F. BARKER AND O. S. DUFFENDACK. *Phys. Rev.* 26, 339-45(1925).—With HCl flowing continuously through a 3-element discharge tube so that it passed through the observation chamber where the electron impacts occurred before it reached the filament, no H lines appeared up to acceleration voltages of 120 v. Current-voltage curves showed a crit. potential at 14 v. which is attributed to the ionization of the mol. without dissociation. No band spectra of between 6000 and 2000 Å. accompany this excitation; hence it is concluded that the mol. has no electron transitions between 2 and 6 v., but that the electron is probably bound in a single operation with consequent radiation of energy equiv. to 14 v. D. C. BARDWELL

Negative-ion emission from oxide-coated filaments. H. A. BARTON. *Phys. Rev.* 26, 360-3(1925).—Negative ions emitted from an oxide-coated Pt filament were shown by a mass spectrograph to be O_2^- , formed by disintegration of the oxide coating. D. C. BARDWELL

Three examples illustrating X-ray methods of supplementing and correcting crystallographic data. KATHLEEN YARDLEY. *Phil. Mag.* 50, 864-78(1925).—The limitation of goniometric and of X-ray spectrometric measurements are discussed and compared. The comparisons are illustrated by potassium hydrogen chloromaleate, ammonium chlorofumarate and ammonium hydrogen fumarate. S. C. L.

A note on the vibration of the CO_2 ion. S. CHAPMAN AND A. E. LUDLAM. *Phil. Mag.* 50, 822-4(1925).—C. and L. attempt to improve the theory proposed by Kornfeld (*C. A.* 18, 3313) for the structure of the CO_2 ion in a crystal lattice to account for its infra-red frequencies of vibrations. While some improvement is effected, difficulties remain which probably can be met only by taking account of the influence of surrounding ions in the crystal. S. C. L.

Directed quanta of scattered X-rays. A. H. COMPTON AND A. W. SIMON. *Phys. Rev.* 26, 290-9(1925); cf. *C. A.* 19, 1534.—Out of 38 cases where recoil tracks and β -ray tracks are found on the photograph of tracks from X-rays, the direction of scattering is in 18 cases within 20° of that to be expected if the X-ray is scattered as a quantum so that energy and momentum are conserved during the inter-action between the radiation and the recoil electron. The chance that this agreement is accidental is 1 in 259, thus giving direct proof that at least part of the scattered X-rays proceed in directed quanta of radiant energy. D. C. BARDWELL

Experiments on the wave length of scattered X-rays. S. K. ALLISON AND WM. DUANE. *Phys. Rev.* 26, 300-9(1925).—The Compton theory of the shift in the max.

intensity of the modified band is confirmed in general for Li, Al, Be, C, Na, NaCl, Mg, W and S.

D. C. BARDWELL

High-energy γ -rays and their photoelectric effect. M. DE BROGLIE. *Nature* 115, 461(1925) (in French).—The work of Black (cf. *C. A.* 19, 1530) is in accord with that of Thibaud (cf. *C. A.* 19, 1225), who observed the conversion of γ -rays of 2 million v. by photoelectric effect in the K and L orbits of heavy atoms, the effect being very intense with lighter atoms such as Ce, Sb, Sn, Ag, Cu and Fe, and who verified precisely the quantum relation for this effect.

GERALD L. WENDT

The Zeeman effect in strong magnetic fields. P. KAPITZA AND H. W. B. SKINNER. *Proc. Roy. Soc. (London)* 109A, 224-39(1925).—A method of utilizing the transient magnetic fields (up to 130,000 gauss), produced by accumulator discharges through a coil, for the study of the Zeeman effect is given. The method involves photographing a spectrum with an exposure of not more than 1/300 sec., and a means for doing this with a high-dispersion quartz spectrograph is described. It consists of a special application of a large condenser battery to give a single localized spark, the spark being timed to occur at the moment when the max. field strength is attained. For spark electrodes the metals Cu, Al, Zn and Mg were used. On account of the high vapor pressures developed in a momentary spark considerable difficulty was experienced in obtaining sharp spectral images, but fairly consistent results were obtained by photometric measurement of some Zeeman patterns for strong doublets, singlets and triplets in these spectra. The magnetic resolutions are approx. what would be expected from the usual expts. on the Zeeman effect if the separations increase proportionally to the field strength. Evidence is positive, however, that for the s-p combinations of Zn and Hg, the splitting is not strictly proportional to the field strength between fields of 70,000 and 130,000 gauss; at the latter value it is 10% greater than would be expected. The splitting of the s-p combinations in doublet and singlet spectra seems to be normal. Three cases of Paschen-Back effect are discussed in connection with observations on the Ca diffuse doublet (3159, 3179, 3181 Å. U.) and the pp' groups for Mg and Be.

W. F. MEGGERS

The structure of the K_{α} lines of molybdenum. F. K. RICHTMYER AND R. C. SPENCER. *Phys. Rev.* 23, 550-1(1924).—With a Mo water-cooled target and an ionization chamber of high resolving power a search was made for the faint lines in the neighborhood of K_{α} discovered for the lighter elements by other investigators and attributed to multiply ionized K shells. No lines were found. By studying the line width as a function of slit width it is shown that the width of $K_{\alpha 1}$ is probably not greater than 0.0003 Å. U.

W. F. MEGGERS

The mechanism of the quantum relationships in black body radiation. SATYENDRA RAY. *Z. Physik* 32, 473-6(1925).—R. claims to have shown in previous articles by two different lines of reasoning that in a light wave the ratio between amplitude and wave length must be const., and he has further shown that this assumption is contained in the Bohr theory. In the present article he arrives at the same conclusions for heat waves on the basis of thermodynamical reasoning. The expression as obtained involves the idea of a discreet sub-electronic elec. structure of the ether, the frequency of vibration of one of the ether particles being assumed const. over time intervals of a second. The reasoning also contains the assumption of what the author terms Doppler's principle; to wit, that amplitude divided by the wave length is a const., for the equation deduced contains beside this factor and a const. only the velocity light. Thus in postulating the constancy of the velocity of light, it is not surprising that the Doppler principle follows from the equation.

L. B. LOEB

The theory of the radiometer. H. E. MARSH, E. CONDON AND L. B. LOEB. *J. Opt. Soc. Am.* 11, 257-62(1925).—Although the theory of repulsion radiometers is fairly well developed by the recent work of Hettner and Czerny, that of the ordinary vane radiometer commonly seen in opticians' windows is very unsatisfactory. Recently A. Einstein has proposed a theory giving the magnitude of the effect in order of magnitude only. Contrary to the accepted beliefs this makes the action dependent on a narrow strip of the vane, of the dimensions of mol. free path at the existing pressure, along the edge of the vane. Such an action would make the torque on a vane having a large edge moment greater than one having a smaller edge moment and the same area. The authors tested this and find the effect as predicted. The torque does not appear to be proportional to the edge moment, however. It was also found that pressure variations of the torque were present which are not included in Einstein's theory. In a forthcoming paper by H. E. Marsh in the *J. Opt. Soc. Am.*, it will be shown that both these deviations from the Einstein theory are due to temp. differences which were not detd. in the article being abstracted. It will further be shown that the torque

observed is in good agreement in order of magnitude with the Einstein theory.

L. B. LOEB

Comet-tail spectrum and Deslandres' first negative group. H. B. LEMON. *Proc. Nat. Acad. Sci.* 11, 41-3 (1925).—A long vacuum tube of the Wood type filled with He pumped by circulation through activated C furnishes an extremely brilliant comet-tail spectrum provided the partial pressure of the C compds. is of the order 10^{-6} mm. The compn. of the residual C compds. is quantitatively unknown, although CO_2 and certain hydrocarbons are present. The He plays only a secondary role in the excitation of these spectra, but nevertheless is necessary for their production with great intensity.

B. C. A.

Law of variation with temperature of the conductivity of solid salts, and possible relationship to the characteristic spectrum of the metal of the salt. P. VAILLANT. *Compt. rend.* 180, 206-8 (1925).—If the liberation of electrons that carry the current which flows when an e. m. f. is applied to a layer of a solid salt (cf. C. A. 19, 2770) is caused by the absorption of radiant energy produced by a monochromatic radiation of wave length λ , then the coeff. K , which connects the densities of the liberated electrons, n_1 , with that of the particles giving rise to them, n_2 ($Kn = n_1^2$), should vary with temp. and follow the same law as this radiation, viz., $K = K_0 e^{-hc/\nu T \lambda}$, where h = Planck's const., c = velocity of light. The wave lengths, λ , calcd. in this way for the salts of Na, K and Li are, within the limits of exptl. error, those of the chief lines in the spectra of the elements.

B. C. A.

A peculiarity of some red neon lines. W. H. J. CHILDS. *Nature* 115, 572 (1925).—The wave length of the reversal of λ 6402 was found to be 6402.251 ± 0.001 A. U.

FLORENCE N. SCHOTT

Spectroscopic determination of electron affinity of halogens. E. V. ANGERER AND A. MÜLLER. *Physik. Z.* 26, 643 (1925).—The long-wave absorption limit of thermally dissociated alkali halide vapors yields a measure of the electron affinity of the halogen atoms. The following values were obtained:

Salt	KF	NaCl	CsCl	KBr	CsBr	KI
Å. units	3030	3280	3170	3590	3490	3980
Cal	94.0	86.6	89.6	79.1	81.3	71.3

Vapor density and temp. yield no marked influence on the precision with which the absorption limit may be evaluated.

F. C. KRACEK

The origin of some band spectra. M. DUFFIEUX. *Ann. phys.* [10] 4, 249-318 (1925).—The widths of spectrum lines emitted by gaseous particles are explained largely as Doppler-Fizeau effects resulting from the thermal agitation of the particles. Other causes which contribute to the widths of the lines are discussed. The formula for the half-width of a spectrum line (the distance between the abscissas of those points of the interference pattern at which the intensity is half the max.) is shown to depend directly on the abs. temp. and inversely on the mass of the emitting particle. It is, therefore, possible to deduce the masses of the particles by measuring the half-widths of the lines at const. temps. The Fabry-Perot interferometer was used in making observations of the limiting orders of interference for lines in various spectra. From the tabulated details of the observations it is concluded that the mol. H_2 emits the H secondary spectrum; the mol. N_2 emits the first positive group of N; the atom N emits the second positive group of N, the negative group of N, and the two cyanogen groups at 3883 A. U. and 4212 A. U.; the atom O emits the bands of the CO spectrum, that at 4123 A. U., however, probably originating in the C atom.

C. C. KRESS

Mass spectra of some light elements. J.-L. COSTA. *Ann. phys.* 4, 425-56 (1925).—A mass spectrograph is described, similar to that of Aston but of greater precision, which was used in measuring the masses of H, He, Li, C and N. The method of measurement consisted in photographing two masses of known ratio under conditions in which the magnetic field was maintained const., but the elec. field was varied so as to be a little less and a little larger than the ratio of the masses. In this way a scale of the spectrograph is secured for dispersion of mass with varying field, permitting the precise detn. of an unknown mass whose image on the photographic plate lies between two successive images of the known mass, the field strength producing it being known. The ratio of the masses $\text{H}:\text{H}_2$ thus measured was found to be exactly 1:2. For He and H_2 the ratio 2.0148 was measured; for He:C the measurements gave 1:3. Li has two isotopes of masses 6 and 7. The mass of Li^6 compared with He was found to be 6.009, that of Li^7 compared with N (14.008) was found to lie between 7.010 and 7.013. Measurements on N indicate that its mass is greater than 14 but less than 14.008 assigned by chemists.

C. C. KRESS

Structure of the nickel spectrum. II. KARL BECHERT. *Ann. Physik* 77, 537-59 (1925).—Previous work on the structure of the Ni arc spectrum (*C. A.* 19, 3427) classified many of the lines in multiplets of the singlet and triplet series systems and combinations between them. The present work classifies additional lines in the triplet and quintet systems, and in combinations between the triplet and quintet systems and between the singlet and quintet systems. About 220 lines are tabulated in addition to those previously classified. Comparison of the term-structure of Ni with those of Fe and Co shows a striking resemblance between them as regards the distribution of the higher terms. The septs. ($\Delta\nu$) of complex terms, however, show a rapid increase in passing from Fe (approx. 300 cm^{-1}) through Co (approx. 600 cm^{-1}) to Ni (approx. 900 cm^{-1}). C. C. KRESS

Infra-red absorption spectra. Experimental and theoretical determination of the infra-red absorption spectra of some organic compounds. LADISLAUS MÁRTON. *Z. physik. Chem.* 117, 97-128 (1925).—The near infra-red absorption spectra of some org. compds. were measured with a thermopile, the light of a Nernst glower after passing through the absorbing media being dispersed in a prism spectrometer. Numerical data and graphs are given for the following compds.: Hexane, cyclohexane and homologs, benzene and homologs, some aliphatic aldehydes, acetone, chloroform, phosgene, and thiophosgene. All these substances have similar absorption spectra between 1.1 μ and 4 μ . The following differences, however, have been noted: from hexane to cyclohexane all the bands are displaced toward longer wave lengths and become more intense; the homologs of the various substances differ only in the variations in intensity of the bands; the bands of compds. with unsaturated bonds are displaced toward shorter wave lengths. The bands may be represented by a formula of the type $\nu_s = \nu_0(1 - px)$, which describes the anharmonic oscillations of the mols. ν_0 is the fundamental frequency of the oscillator and p is a variable assuming successive integral values. A table compares the calcd. values of ν_s for several compds. with those derived from the measurements. C. C. KRESS

Change of wave lengths for certain lines of zinc, cadmium and mercury in a condensed discharge. MITSU HARU FUKUDA. *Sci. Papers Inst. Phys. Chem. Research, Japan* 3, 183-92 (1925) (in English).—Lines in the spectra of Zn, Cd and Hg, excited in capillary tubes by condensed discharges, were observed to undergo changes in wave length. The shifted lines are mostly members of the sharp series and the displacement is toward increasing wave lengths. Of the diffuse series lines some shifted toward the red, others toward the violet. The shifts increased as the spark gap, inserted in series with the tube, was lengthened. The wave-length changes are attributed to Stark effects produced by the elec. field of the closely crowded ions in the capillary of the tube. C. C. KRESS

Complementary researches on the structure and distribution of band spectra. H. DESLANDRES. *Compt. rend.* 181, 265-71 (1925).—The relation previously found for expressing the members of band series in terms of a fundamental frequency d_1 1062.5 (*C. A.* 19, 2782) is shown to hold for the infra-red absorption bands of NH_3 . The bands of HF, HCl and HBr are likewise expressible in terms of d_1 . These bands have well-observed secondary max. the frequencies of which are fractional parts of d_1 . The denominators of the fractions are related to the atomic no. of the heavier atom of the mol. but more work will be required to establish the precise relationship. C. C. KRESS

Complementary investigations on the structure and distribution of band spectra. H. DESLANDRES. *Compt. rend.* 181, 387-92 (1925).—Previous work (*C. A.* 19, 606, 2299, 2782, and preceding abstr.) has shown that the frequencies of the absorption bands of simple gaseous compds. may be represented by the formula $\nu = qd_1/rs = q'd_1/r's'$ in which the fundamental frequency $d_1 = 1062.5$, s is the no. of atoms comprised in the mols., s' is the no. of free positive charges on the nucleus of the heavier atom, and q, r, q', r' are integers. Recent studies of the absorption spectra of CH_4 , C_2H_2 , C_2H_4 , CHCl_3 , CCl_4 , C_2H_6 , CO_2 , H_2S , SO_2 , CS_2 and solid cryst. S, and also the emission bands of CO_2 and CO , prove them all to be satisfactorily represented by the above formula. As in previous investigations those bands are strongest for which $r = 1$. C. C. KRESS

The regularities in the resonance spectrum of iodine vapor and the calculation of the moment of inertia. A. KRATZER AND ELIS. SUDHOLT. *Z. Physik* 33, 144-52 (1925).—The regularities detected by Mecke in the resonance spectrum of I excited by the green Hg line (*C. A.* 17, 2994) are shown to be in agreement with the theoretical formula for band spectra. For the moment of inertia of the unexcited I mol. the value $8.63 \times 10^{-39} \text{ g. cm}^2$ has been calcd. The distance between the atoms of the mol. comes out $r = 2.87 \times 10^{-8} \text{ cm}$. C. C. KRESS

The influence of an alternating magnetic field on the polarization of resonance radiation. E. FERMI and F. RASSETTI. *Z. Physik* 33, 246-50; *Atti accad. Lincei* 2, 117-20(1925).—An expt. is described for measuring the effect on the polarization of the resonance radiation of Hg of a magnetic field of const. amplitude but of variable frequency. The results of the observations do not permit derivation of quant. relations between the amt. of polarization and frequency of the field, but qualitatively there is for certain amplitudes an increase of polarization with frequency, and for others the polarization remains const. as the frequency increases. The results also indicate that the Larmor precession is $3/2$ the normal for the Hg line 2536 A. U. C. C. KIESS

Intensity of multiple spectral lines: experiment and theory. I. S. ORNSTEIN. *Proc. Phys. Soc. (London)* 37, 334-7(1925).—An address. C. C. KIESS

The series spectrum of gold. J. C. McLENNAN and A. B. McLAY. *Proc. Roy. Soc. (London)* 108A, 571-82(1925).—Absorption expts. with Au vapor indicate that the pair of ultra-violet lines 1665.7 A. U. and 1646.7 A. U. constitutes the second member of the principal series of the Au arc spectrum. In addn. two other ultra-violet lines 1951 A. U. and 1879 A. U. are easily absorbed and are shown to be combinations between the low σ term and two irregular π terms which are not a part of the term system that gives rise to the principal and sharp series. The sharp and diffuse series as given by Thorsen (*C. A.* 17, 3135) are recalcd. with wave lengths reduced to the international system. The three lines 6278 A. U., 5230 A. U., and 5064 A. U. are shown to originate in a transition between the low π levels and a still lower pair of δ levels, the latter constituting a metastable state. The classified lines with their series designations are tabulated. C. C. KIESS

A high-vacuum spectrograph for X-ray measurements and some preliminary results. ROBERT THORAEUS and MANNE SIEGBAHN. *Arkiv Mat. Astron. Fysik* 19A, No. 12, pp. 1-9(1925) (in English).—A new vacuum spectrograph for measurement of the longer X-rays up to and exceeding 20 A. U. is described. Preliminary observations with it yield the following results: 18.37 A. U. for the line $K\alpha$ of Fe; 17.60 A. U. and 17.27 A. U. for the $L\alpha$ and $L\beta$ lines of Fe; 19.48 A. U. and 19.17 A. U. for the $L\alpha$ and $L\beta$ lines of Mn; and 21.69 A. U. and 21.35 A. U. for the corresponding lines of Cr. C. C. KIESS

Wave lengths of additional lines in the many-lined spectrum of hydrogen. T. TANAKA. *Proc. Roy. Soc. (London)* 108A, 592-606(1925).—Two spectrograms of the secondary spectrum of H have been measured to secure wave lengths of faint lines not hitherto published. To eliminate lines due to oxyhydrogen bands spectrograms were made of a H flame fed by a current of O., OH lines were measured between 3525 A. U. and 3428 A. U. These are tabulated. In the H_2 spectrum approx. 600 faint lines were measured between 6572 A. U. and 3295 A. U. These new wave lengths have been used in the analysis of the H_2 spectrum for band series; see preceding abstract. C. C. KIESS

The secondary spectrum of hydrogen at higher pressures. IAN SANDEMAN. *Proc. Roy. Soc. (London)*, 108A, 607-16(1925).—The spectrum of H_2 was photographed when an arc between W electrodes was operated in H at high pressures. The behavior of certain H_2 lines under such conditions of excitation affords a method of relating them in series. In the blue between 4450 A. U. and 5000 A. U. is a group of strong lines which has been classified into a P, Q and R combination. The Q series has 8 members, those corresponding to even quantum integers being more intense than the odd. The P and R branches are short. From the consts. of the series formulas a moment of inertia equal to 19.326×10^{-41} g. cm.² has been calcd. This agrees exactly with the value calcd. for a particular configuration of the static model of H_2 . The P, Q and R combination in the yellow (cf. Richardson and Tanaka, *C. A.* 19, 778) appears under the same conditions of excitation as the blue band, both having the same intensity distributions. C. C. K.

The distribution of intensity in the X-ray spectra of certain long-chain organic compounds. G. SHEARER. *Proc. Roy. Soc. (London)* 108A, 655-66(1925).—Recent studies by various X-ray workers has included many org. compds. having as the basis of their structure a long chain of C atoms. From the viewpoint of the crystal structure of the compds. it is found that there is one set of planes in the crystal with a much longer spacing than any of the others. Two groups of crystals are recognized: (1) those in which the planes are sepd. by the length of a single mol.; (2) those in which they are sepd. by the length of two mols. Theoretical values are calcd. for the intensity of the various orders of X-ray spectra reflected from the planes of crystals of both groups and these are shown to be in agreement with observed results. With the hydrocarbons (group 1) there is a slow decrease of intensity with increase of order. With the fatty acids and alcohols (group 2) the even orders are very weak compared to the odd orders. The ketones and esters exhibit similar behavior. By regarding them as equiv. to two

half-mols. arranged end to end in opposite directions they come under group 2 and exhibit a gradual decrease in intensity with increasing order on which is superposed a periodic variation depending on the distance of the O atom from the end of the mol.

C. C. K.

The intensities of lines in multiplets. II. Observed data. H. N. RUSSELL. *Proc. Nat. Acad. Sci.* 11, 322-8(1925).—The theoretical values for intensities of spectral lines in multiplets (*C. A.* 19, 2782) are compared with the few precise intensity measurements which have been made and the agreement between the two is satisfactory. For the great majority of classified spectrum lines, however, there are no precise intensity measurements, but for many of them there exist intensity estimates made by King in his studies of the variations of spectra with temp. King's estimates are very nearly proportional to the square roots of the actual intensities. The observed estd. intensities of lines belonging to 231 multiplets of 46 types are compared with their theoretical values and the agreement is remarkably close.

C. C. KIESS

Multiple electron transitions and primed spectral terms. A. E. RUARK. *J. Opt. Soc. America* 11, 199-211(1925).—Mg vapor was excited in the force-free space between the cylinder and grid of a 3-electrode tube. It was found that the lines of Mg^+ appeared at voltages which were equal to the ionization potential of Mg plus the voltages required from the series classification of the lines to excite them. The $2p-2p'$ group, included between 2776 A. U. and 2783 A. U., was excited at an applied potential of 7.9 v., which shows that these lines appear at their quantum voltages resulting from single electron impacts which move two electrons simultaneously to higher orbits. Similarly the pp' group of Cd (2239 A. U. to 2329 A. U.) was excited at its quantum voltage. In the Cd low-voltage arc new lines were observed which have been classified as members of the singlet and triplet subordinate series.

C. C. KIESS

The structure of the red lithium line λ 6708. J. B. GREEN. *J. Opt. Soc. America* 11, 213-6(1925).—The red line of Li excited under varying conditions of vapor density and current in a vacuum arc was observed with the high resolution afforded by a Lummer plate to det. its structure. At low vapor densities the line appears as a simple doublet. With increasing vapor density each member of the doublet reverses, the reversals widening until the inner components overlap, giving the appearance of a triplet. At high densities the reversals merge and the line appears as a single reversal with broad wings. (For similar behavior of the green Tl line and other lines see *C. A.* 19, 1374.)

C. C. KIESS

Structure in the secondary hydrogen spectrum. I. O. W. RICHARDSON. *Proc. Roy. Soc. (London)* 108A, 553-61(1925). **II.** *Ibid* 109A, 35-56.—The details of the analysis of the secondary spectrum of H, promised in a previous paper (*C. A.* 19, 778), are tabulated in these 2 papers. Numerous series of the P, Q and R types, some probably tentative, are presented. **III.** *Ibid* 239-66.—Previous work (*C. A.* 19, 778) on the secondary spectrum of H has classified into band series lines which are selectively weakened when the spectrum is excited by the method recently described (*C. A.* 19, 776). Investigation of the series relationships of the remaining lines has permitted the classification of about 130 additional lines into band series with P, Q and R branches. The moments of inertia of the emitting mols. calcd. from the new series coincide with values previously found from the band series already published.

C. C. KIESS

The excitation of the band spectrum of helium. T. R. MERTON AND J. G. PILLEY. *Proc. Roy. Soc. (London)* 109A, 267-72(1925).—Methods and app. for exciting the band spectrum of He are described. In particular the behavior of the bands under varying conditions of excitation was studied. It was found that the green band including lines from 5386 A. U. to 5276 A. U., which has hitherto been observed only faintly, can be selectively enhanced.

C. C. KIESS

The arc spectrum of palladium, its Zeeman effect and spectral type. C. S. BEALS. *Proc. Roy. Soc. (London)* 109A, 369-84(1925).—The Zeeman effect was observed for lines in the spectrum of Pd from 4473 A. U. to 2447 A. U. Comparison of the observed magnetic resolutions with those calcd. from Landé's theory has permitted the assignment of term combinations to all the lines, and has led to the classification into multiplets of some of the lines. The arc spectrum is thus seen to consist of singlet and triplet systems with combinations between the two. The lowest term of the arc spectrum is a triplet d between the components of which the const. wave-no. differences 4972.0 and 3377.6 cm^{-1} occur.

C. C. KIESS

Regularities in the hyperfine structure of spectral lines. GEORG JOOS. *Physik. Z.* 26, 380-2(1925).—The hyperfine structure of a Cd triplet and the Bi λ 4722 line points strongly to the existence of another quantum no. "f." The selection principle is still valid for inner quantum nos. Similarly the fine structure of Hg lines and other

elements is accounted for by term splitting (cf. Ruark, Mohler, Chenault, *Nature* 114, 475).

H. R. MOORE

A note on the spectra of silicon and aluminium. W. C. MCQUARRIE. *Phil. Mag.* 50, 819-21(1925).—In an attempt to det. the lines of Si by measurement of the absorption of the under-water spark, an alloy of 70% Al, 30% Si was used. The same Al absorption lines as found by L. and E. Bloch (*C. A.* 17, 673) were measured and in addn. 12 new ones. Si absorptions were also observed and identified with the Popow series (*C. A.* 9, 884) but were not measured.

S. C. L.

The spectrum of potassium at low voltages. F. H. NEWMAN. *Phil. Mag.* 50, 796-803(1925).—After a discussion of the propagation of an arc at a voltage less than the ionization potential of the vapor, as well as general energy considerations in electron-atom systems, N. described expts. with K vapor at 245° C., when the vapor pressure of K is about 0.1 mm. A table and a plate show the spectral lines obtained with various voltages: for the orbital transfer $1\sigma-1\pi$, 7665 and 7699 with 1.9 v. (1.61 calcd.); for $1\pi-2\sigma$, 12,434 and 12,523 with 2.50 v. (calcd.); for $1\pi-2\delta$, 11,690 and 11,772 with 2.66 v. (calcd.); for $1\sigma-2\pi$, 4044 and 4047 with 3.3 v. (3.05 calcd.); for $1\pi-3\delta$, 6936 and 6965 with 3.7 v. (3.38 calcd.); for $1\pi-3\sigma$, 6911 and 6939 with 3.7 v. (3.39 calcd.); for $1\sigma-3\pi$, 3447 and 3448 with 3.9 v. (3.58 calcd.). The exptl. value for the complete arc spectrum of K vapor was 4.4 v. and the calcd. value 3.32.

S. C. L.

Fine structure, absorption and Zeeman effect of the 2536 mercury line. R. W. WOOD. *Phil. Mag.* 50, 761-74(1925); cf. *C. A.* 19, 776.—The intensity of the 2536 Hg line was increased 8 fold by using a magnet to press the discharge against the wall the discharge tube. A Rochon quartz prism was used to polarize the light. Three different types of Hg arc lamps were employed for different conditions. Five components of the 2536 line were revealed, sepd. by intervals 0.014, 0.010, 0.011 and 0.011 A.U. resp., or a total sepn. of about 0.05 A.U. Reversal may make each of the 5 lines appear double. Absorption nos. between 5 and 10 may be obtained as well as other more complicated types. 3 cm. pressure of N₂ produces the same change in the absorption of Hg as produced by raising its vapor pressure from 0° to 25° C., or about a 10-fold increase. The study of the Zeeman effect was rendered very difficult by the tendency of the magnetic field to extinguish the Hg arc, preventing observation. Various effects were detected at different current strengths through the magnet which will be further studied.

S. C. L.

Optical excitation of the mercury spectrum with controlled orbital transfers of electrons. R. W. WOOD. *Phil. Mag.* 50, 774-96(1925).—This paper contains an account of the orbital transfers or various spectral lines which accompany the excitation of the Hg line 2536 A. U. The transfers are presented in the form of a diagram showing the orbits and orbital transfers for about 30 lines, the wave lengths and intensities of which are given in a table. The prepn., use and results obtained with Br₂ and Cl₂ gas filters as a means of analysis are described; also the very interesting effect of N₂ and other gases. A table is given showing how He and CO affect the intensity of different lines, increasing or decreasing part of them, while leaving others the same. These different effects of foreign gases have been qualitatively distinguished: (1) the accumulation of electrons in the metastable 2p₃ orbit in a large no. of atoms, resulting in the powerful absorption of lines which terminate on that orbit and the enhancement of these lines in the optically excited spectrum; (2) the emission of forbidden lines in the optically excited spectrum which is provisionally ascribed to the excitation of these Hg lines by N₂ brought into the excited state by excited Hg; and (3) an effect produced by foreign gases at very low pressures (0.01 mm.) for which no theory is advanced.

S. C. LIND

The molecular scattering of light in liquids. K. S. KRISHNAN. *Phil. Mag.* 50, 697-715(1925).—Measurements are given of the intensity and imperfection of polarization for different spectral regions of the light transversely scattered by 65 different dust-free org. liquids. Some of the liquids are feebly fluorescent, generally toward the blue end of the spectrum. In some of the liquids there appears to be a genuine dependence on wave length of the depolarization; the imperfection of polarization increases with wave length. The theoretical formula for intensity fails in the liquids of high refraction, which are also the ones showing high polarization. The prominent relations between depolarization and chem. constitution are pointed out.

S. C. L.

Series spectra of two-valence-electron atoms of boron and carbon. I. S. BOWEN AND R. A. MILLIKAN. *Phys. Rev.* 26, 310-8(1925); cf. *C. A.* 19, 2781.—By methods previously described, additional lines of B_{II} and C_{II} are identified. The progression of frequency sepn. and screening const. for regular doublets for Li to O are shown in a table.

D. C. BARDWELL

Measurements of the relative intensities of the doublets of the alkali metals in the principal series. F. W. ÖÖDR. *Z. Physik* 33, 656-7 (1925).—The relative intensities of the doublets of the principal series of Rb and Cs in flames have been measured. The ratio of intensities of $1s-3p_1$ to $1s-3p_2$ and of $1s-4p_1$ to $1s-4p_2$ of Rb in a flame is 2:1 in both cases. The ratio of $1s-3p_1$ to $1s-3p_2$ of Cs in a flame varied widely, but in an arc was found to be 2:1. H. C. U.

Intensity relations of some intercombination lines. T. BOUMA. *Z. Physik* 33, 658-9 (1925).—The ratio of intensities of the mercury lines $1P-2d_3$ to $1P-2D$; $1P-3d_3$ to $1P-3D$; and $1P-4d_3$ to $1P-4D$ were found to be 100:100; 42:100; and 24:100, resp. The lines $1P-nd_3$, $1P-nd_5$, and $1P-nD$ cannot be regarded as a multiplet, since in that case the relative intensities should not vary with n . H. C. U.

The interpretation of complicated spectra. F. HUND. *Z. Physik* 33, 345-71 (1925).—On the basis of the suggestions of Russel and Saunders, Pauli and Heisenberg on the interaction of electrons in emitting light, the spectral terms of some elements have been correlated to definite quantum nos. which specify the arrangements of the electrons in the atoms. For Sc it is found that the first electron to be added to the Sc^{++} ion goes into a $3s$ orbit giving a doublet 2D term as the normal state of Sc^{++} . The next electron enters a $4s$ orbit and gives a 4D term for the normal state for the Sc^+ . The last electron enters a $4s$ orbit and gives a 2D term for the normal state. The predicted terms for the normal states agree with the exptly. observed terms. It is noted that for terms of the same quantum nos. (*i. e.* the azimuthal quantum nos. of the electrons which do not form a closed shell) that term which has the highest multiplicity lies lowest. Making use of this rule it has been possible to give the type of term ($S, P, ^3D, F, G$, etc.) and its multiplicity for the normal states of the second short series of the periodic table and for the elements from Sc to Zn. The predicted term agrees with experiment for all cases in which the spectra are known with the exception of Cr. In this case the term for four electrons in the $3s$ shell and two in the $4s$ shell was predicted and experiment agrees with five electrons in the $3s$ shell and one in the $4s$ shell. The spectra of O, Ne, Sn and Pb are discussed and found to agree with theory. The singly ionized atoms from Ca to Fe inclusive are also considered and excellent agreement between calcn. and expt. is secured. H. C. U.

The phase rule and its application to problems of luminescence and ionization of gases. MEGHNAD SAHA. *Quart. J. Indian Chem. Soc.* 2, 49-60.—The ionization theory is mathematically discussed from the standpoint of the phase rule for the ionization of Ca gas into Ca^+ and e ; for the ionization of Ca gas in an atmosphere containing an excess of electrons; for the double ionization of Ca; and for the double ionization of Ca, but with an arbitrary concn. of electrons. The role of radiation in detg. the equil. is discussed, but the equations are not worked out. MARIE FARNSWORTH

Simple preparation of substances showing both fluorescence and phosphorescence. B. BATSCHA. *Z. physik. chem. Unterricht* 38, 25-8 (1925).—Tiede found recently (*C. A.* 16, 2078) that excellent substances for showing both fluorescence and phosphorescence can be made by suspending various org. compds. in molten boric acid. Fluorescein is particularly suitable. B. finds that by suspending it in melted tartaric or citric acid preps. with very brilliant fluorescence and phosphorescence are obtained. M. B.

Efficiency coefficients of phosphores. FELIX SCHMIEDER. *Ann. Physik* 77, 381-416 (1925).—According to Stokes' law the wave length of emitted phosphorescent light is always greater than that of the exciting source. Nevertheless, the present studies on $CaS-Bi$ phosphores show that the 2 wave lengths are identical within exptl. error. Thus the exciting λ 436μ was found to evoke a fluorescent band max. at λ 440μ . When the temp. of the phosphorescent layer was raised to 550° , the efficiency coeff. (ratio of the wave lengths of exciting and emitted light) was found to be 0.97. This result directly controverts Stokes' law, and indicates transformation of a large no. of small energy quanta into a smaller no. of larger quanta. Apparently the thermal vibration energies of the heat cond. electrons are integrated by some unknown mechanism into quanta of higher frequency. H. R. MOORE

Some properties of ice crystals. E. K. PLYLER. *J. Elisha Mitchell Sci. Soc.* 41, 18, 39-40 (1925).—The ice forming between crystals has a much higher absorption of infra-red light than the crystals. This holds with frozen tap as well as distd. H_2O . The location of absorption bands in the spectra and the corresponding transmission are given. A. L. MEHRING

A note on the photoactivation of chlorine. E. J. BOWEN. *Phil. Mag.* 50, 879-80 (1925).—B. points out the necessity of taking into account the amt. of light absorbed by Cl_2 as depending on the wave length. Assuming absorption to be proportional

to the extinction coeff., the recent table of W. Taylor (*C. A.* 19, 2604) is corrected as follows:

Range of filter λ	Reaction velocity	Light absorbed (light intensity \times mean absorption)
4300-4800	100	100
4550-5000	27	30
4780-5370	14	13
5050-5570	0	0

From which B. concludes that the Ribaud fine-structure bands of Cl_2 are active, and that the reaction rate is proportional to the no. of light quanta absorbed. A similar error of Coehn and Jung is pointed out (*C. A.* 18, 3144). S. C. LIND

Detection of Au formed from Hg (STAMMREICH) 7.

4—ELECTROCHEMISTRY

COLIN G. FINK

Advances in electrochemistry in the last ten years. FRIEDRICH MÜLLER. *Z. angew. Chem.* 38, 766-71, 865-8, 933-41(1925). E. J. C.

Electrometallurgy of iron and steel in Italy. F. GIOLITTI. *Iron & Steel Can.* 8, 103-6(1925).—A review of the growth in elec. steel and pig iron manuf. in Italy, particularly from 1913 to 1922. W. H. BOYNTON

Electrometallurgical plants in France. CH. A. KELLER. *Arts & Métiers*, July, 1925; *J. four élec.* 34, 195-8(1925).—A popular discussion of the location and economics of electrometallurgical plants in France. C. J. BROCKMAN

Duplex furnace operation in a steel company. ANON. *Elec. World* 86, 854(1925).—A brief account of the multiple 3-ton furnace installation at the Burnside Steel Co., Chicago. One set of electrodes and a single unit of control and transformer equipment are used. One furnace is melting its charge while the other is being tapped and recharged. In this way little time is lost between heats. The charge is preheated with oil. The power demand is 1650 kw. and both furnaces produce 20 tons steel per 10 hr. day. A. D. S.

Induction furnaces in a large brass mill. ANON. *Elec. World* 86, 801(1925).—Twenty-four Ajax-Wyatt induction furnaces are connected in a delta to a 3-phase bus. The nominal charge capacity is 600 lbs. (273 kg.). A 230 v. single-phase 60-cycle circuit is used and the av. current is 400 amp. The power factor is 60-75%. During the pouring period, an 80 v. current for holding the heat is applied from a sep. bus and sep. bank of transformers. Av. performance is about 9 lbs. (4.1 kg.) of metal per kw.-hr., the rate \$0.0125 per kw.-hr., and the current cost \$0.0014 per lb. (45 kg.) of metal. Labor costs are low, on account of the continuous operation. A cross-section of 1 furnace is shown. W. H. BOYNTON

High-frequency induction furnaces for high temperatures. G. RIBAUD. *Compt. rend.* 180, 1733-5(1925).—R. made a study of furnaces having, in principle, a porous C cylinder extending above the graphite heating chamber, all of which is surrounded with lamp black. He describes the method of closing the cylinder which made it possible to attain a temp. of 3000° in the interior of the furnace. The results show that a 10 kw. high frequency furnace, with a vol. of 500 cm.³, may reach a temp. of 2500° as compared with 1700° for a C resistance furnace of like vol. and kw. capacity; with a vol. of 100 cm.³ a temp. of 3000° was attained. One of these furnaces has been used for the transformation of the diamond and has produced more than 50 heats at 2000° without the replacement of porous C. These furnaces have been used for calcining refractories, for detg. points of fusion, etc. A. D. SPILLMAN

Silit. ANON. *Electrician* 95, 387-8(1925).—Silit consists of an intimate mixt. of Si and SiO₂ with a volatile binder which is heated until the Si just softens. Exposure of the forms of mixed Si, SiC and C to the action of CO at 1500° produces a product of high fireproof qualities, resistant to atm. influences, and possessing high and variable sp. resistances. Three grades are made: (1) for resistances subject to permanent loads at glowing temps. and to high momentary loads; (2) for elec. heating resistances up to 1400°; and (3) for fireproof material capable of withstanding violent changes in temps. Applications of each grade and several curves showing sp. properties are indicated. W. H. BOYNTON

Electrodeposition of tungsten (from fused electrolytes). J. A. M. VAN LIEMPT. *Z. Elektrochem.* 31, 249-55(1925).—For the deposition of W in the form of a powder a ternary mixt. of Na, K or Li tungstates is workable at 700–1000°; the lower the temp. the better are the results. Anodes may be of graphite, W or W carbide; cathodes may be a crucible of aluminized iron, chrome-iron, chrome-nickel and Ag, or a bar of these metals in a porcelain crucible. A diaphragm need not be used. Pure Na_2WO_4 electrolyzed in a quartz crucible at 950° with a c. d. of 1500 amp. per sq. dm. at 9 v. between 2 W electrodes gave 60–80% yields of a gray powder that contained 99.3% of W, 0.26% of SiO_2 , and 0.30% of alkali. The reaction is supposed to be due to the action of the electrolytically discharged Na on the Na_2WO_4 . The fusion must at all times remain neutral or slightly alk. W may be deposited on sheets of Cu, Ni or Co which have been previously cleaned and are free from oxide. Cathodes of Fe, Pd and Ag are attacked by the fused bath. The anode should be of W. The best metallic coating of W is deposited from an acid electrolyte of the compn. $\text{Me}_2\text{O} \cdot n\text{WO}_3$ ($n > 1$; Me is Li, Na, K, in decreasing order of efficiency). Continued electrolysis deposits a W bronze ($\text{Na}_2\text{W}_2\text{O}_6$) on the first layer of W, but burnishing with a steel brush readily removes it, leaving a good surface of W. The temp. should be 1000–1050°. With an electrolyte contg. 38% Na_2WO_4 , 32% Li_2WO_4 , 30% WO_3 , and a c. d. of 80 amp. per sq. dm. after 15 min. on sheet Cu at 585–670° there was only a deposition of the bronze; from 835° to 870° there was spotted W-plating; above 1020° a complete covering layer of W was deposited. The c. d. must not fall below 20 amp. per sq. dm. In 10–30 min. the W deposit is 30–100 μ thick. To get a heavier coating the first deposit must be burnished to remove the bronze and then be replated. W plating is not attacked by hot acids. The deposition is supposed to be due to a direct electrolytic decompn. of the acid tungstate and W bronze, the latter decomp. so slowly that it accumulates in large quantities on the cathode in about 30 min. Single crystals of 6 or 8 sides may be grown in poor yields on wires in an acid electrolyte (55% Li_2WO_4 , 45% WO_3) at about 900° with a c. d. of 1.5 amp. per sq. dm. With larger c. d. the crystals become irregular.

C. J. BROCKMAN

Electrolytic hydrogen plant for France. ANON. *Elec. World* 86, 800(1925).—An installation of 600 Knowles standard type cells, each with a capacity of 7500 amps. at 2.5 v., is arranged in 3 batteries of 200 each. Production is 70,000 cu. ft. (1981 cu. m.) of H_2 and 35,000 cu. ft. (990.5 cu. m.) of O_2 per hr. on a consumption of 11,250 kw. hrs. The cells are of the multipolar type and possess the following features: (1) "staggered" leads attached so as to insure even distribution over the surfaces of the electrodes; (2) substitution of "hydraulic" seals for glands, permitting simple insulation of the leads; (3) S-pipe gas mains carried by the cells with an almost vertical glass tube insulator between each 2 cells, so that at no point in the main is there a greater p. d. than between 2 adjoining cells while the insulating gland tube, being nearly vertical, remains free from liquid, thereby guarding against a short circuit at this point; (4) "safety" tubes in each cell; (5) washing of the outgoing gases by the incoming water feed which is automatically controlled.

W. H. BOYNTON

Perborate formation by electrolysis with unsymmetrical alternating current. SVEN BODFORSS and AKSEL ARSTAL. *Z. Elektrochem.* 31, 1-5(1925).—Two electrodes were connected to the source of d. c. through the secondary coil of a transformer, the primary coil of which was in the a. c. circuit; this induced an unsymmetrical a. c. between the electrodes. The anode was a Zn rod in a clay cell outside of which a cathode of Fe, Pt or Zn was symmetrically placed. Electrolysis at -4° with a sin wave frequency of 48 gave max. yields in 15 min. with an electrolyte contg. 5 mols. NaOH and 1 mol. H_2BO_3 in 1 l. After 15 min. of electrolysis the yields decreased slowly. The best current yield was 56.7% figured as H_2O_2 with a c. d. of 6 amp. per sq. dm. and $I_{a.e.}:I_{a.c.} = 1:5.57$; ($I_{a.e.}$ is the effective a. c.). Curves showing the influence of c. d., temp., time, ratio of a. c. to d. c., and compn. of the electrolyte are given. Pure a. c. forms no perborate. There is no direct relation between the peroxide formation and the corrosion of the Zn anode. The influence of the a. c. on the course of the reaction is discussed, but no electrode potential measurements are given.

C. J. B.

Conduction by metallic colloids and their electrotechnical applications. H. ANDRE. *Compt. rend.* 181, 243(1925).—In the electrolysis of concd. H_2SO_4 , using 2 Ag electrodes and a c. c., the resistivity diminishes as the p. d. between the electrodes drops. With an electrode of colloidal Ag and an unattackable metallic oxide a current is obtained sufficient to charge accumulators. The effective voltage set up by different cathodes may vary from 8 v., for pure Cu, to 80 v. for Si; a c. d. of 1–2 amp. /cm.² was used. It is possible to obtain a thermionic function in drying out the colloids. The current is established at 300–400° and ceases upon cooling.

A. D. SPILLMAN

The valve as oscillation generator. D. G. BOWER. *Electrician* 95, 412-4 (1925).—B. describes the efficiency of the triode when used as an oscillation generator, the conditions to be satisfied, and the favorable effect on the output. The valve must be capable of amplifying, and it must possess unilateral impedence. The amplitude of the oscillations are detd. by the tube constns. and more particularly by the factors which limit the flow of current through the valve. The conventional form of the triode radio frequency power assembly is illusd. If X equals the efficiency, the output power is given by $P_0 = XP_p/(1-X)$, where P_0 = the power delivered to load, and P_p = power the plate is capable of dissipating. Small valves are operated at high efficiency under constant oscillation production. W. H. BOYNTON

A study of liquid dielectrics. I. Effect of moisture and air content. W. P. DAVEY AND T. A. WILSON. *Gen. Elec. Rev.* 28, 770-81 (1925).—Expts. are described involving the study of the insulating characteristics of *linseed oil* as a means of judging the characteristics of *transil oil*, most of which it possesses to a marked degree. The app. and general exptl. method for d. c. leak tests are fully described. Results show that: (1) absorption of linseed oil by the spacer causes segregation of the originally contained water and air into bubbles; (2) removal of this water and air from the spacer increases the effective resistance of condensers to d. c. leak 12,000 times at room temp. and 900 times at 90°; (3) removal of air from the dielectric increases the effective resistance over 140 times; and (4) extreme removal of contained air, water and volatile oxidation products from spacer and dielectric increase the effective resistance to d. c. leak 4500 times at 90°. W. H. BOYNTON

Sealing composition containing S and fibrous material (U. S. pat. 1,557,231) 18.

Electric batteries. S. APOSTOLOFF. U. S. 1,551,359, Aug. 25. An electrolyte contg. a porous or spongy siliceous material such as pumice or kieselguhr together with a binder, e. g., alum, portland cement, magnesia or silica, is used in batteries of the dry cell type having a "bobbin" of C.

Primary electric battery. I. DARIMONT. U. S. 1,560,379, Nov. 3. A battery of the 2-fluid diaphragm type comprises an "exciter mass" which includes NaCl or other "exciter proper" together with CaCO_3 or other substantially insol. antacid capable of decomposing FeCl_3 , and an agglutinating substance such as starch, glue or flour for emulsifying the antacid powder. The battery has a depolarizer of FeCl_3 , a Cr compd. such as CrO_3 for increasing the elec. capacity of the depolarizer, and a soln. of NaCl for increasing the cond. of the dild. soln. of FeCl_3 and for regulating the osmotic pressure.

Paste electrolyte for dry batteries. B. H. TEITELBAUM. U. S. 1,558,413, Oct. 20. NH_4Cl is dissolved in a ZnCl_2 soln., preferably of a strength of 27° Bé. and at a temp. of about 22°, and the temp. is allowed to fall by the endothermic action to about 0°. A cereal mixt. such as starch and flour is then added which will congeal the product without need of cooking it.

Dry-cell battery. J. HARRIS. U. S. 1,560,798, Nov. 10. Structural features.

Composition for coating battery terminals, etc., to prevent corrosion. R. B. CANUTE and E. H. TANK. U. S. 1,558,589, Oct. 27. Na_2CO_3 64, petroleum jelly 80 and oil of cedar 1 part.

Electrolytic cell. I. H. LEVIN. U. S. 1,560,250, Nov. 3. Structural features.

Electrical connections. W. R. MOTT. U. S. 1,559,349, Oct. 27. Low resistance elec. connections adapted for use in electrodes, rheostats, rectifiers, etc., are formed of graphite compressed upon a conductive metal oxide, e. g., PbO .

Storage battery. T. A. EDISON. U. S. 1,559,562, Nov. 3. Separators are formed from asbestos associated with Na_2CO_3 or other carbonate, which is subsequently removed from the formed separators, e. g., by use of a 3% aq. NaOH soln., to give them increased porosity.

Storage battery. H. L. YOUNG and F. W. PLUMB. U. S. 1,561,392, Nov. 10. Structural features.

Storage battery. W. L. SCARFF. U. S. 1,558,927, Oct. 27. Battery separators are formed of the wood of *Chamaecyparis nootkalensis*, which is very durable.

Storage battery. J. F. MONNOT. U. S. 1,557,602, Oct. 20. Structural features.

Storage battery. W. L. WHIDDEN and L. MCCARTNEY. U. S. 1,557,952, Oct. 20. Structural features.

Electric storage battery. E. A. HARRIS. U. S. 1,556,932, Oct. 13. Structural features.

Storage battery container of wood impregnated and coated with rubber. R. N. CHAMBERLAIN. U. S. 1,560,172, Nov. 3.

Storage battery box formed of united hard and soft rubber portions. J. B. MARRISON. U. S. 1,558,384, Oct. 20.

Lead electrode for storage batteries. A. STRASSER. U. S. 1,559,471, Oct. 27. Pb is alloyed with Na or other alkali metal capable of reducing H_2O and this alloy is introduced into perforated shells of insulating material and these shells are dipped into H_2O fully to ext. the alkali metal from the alloy and produce an active mass of porous recrystd. Pb.

Electrolyte-level indicator for storage batteries. R. N. CHAMBERLAIN. U. S. 1,558,076, Oct. 20.

Electrolyte-level indicator for storage batteries. G. A. JENSEN. U. S. 1,556,838, Oct. 13.

Cathodes for vacuum tubes. W. R. BULLIMORE. U. S. 1,558,961, Oct. 27. Cathodes are formed with a core of relatively high specific resistance and m. p. such as an alloy of Ni 80 and Cr 20% coated with noble metal, e. g., Pt, and an active coating comprising alk. earth metal compds., e. g., oxides of Ca, Ba or Sr.

Liquid electrode for heating liquids. O. MEYER-KELLER. U. S. 1,559,447, Oct. 27. Structural features.

Electric furnace producing annular concentric arcs. S. L. TINGLEY. U. S. 1,556,377, Oct. 6. The furnace is adapted for smelting.

Electric arc furnace adapted for brass melting, etc. C. L. IPSEN. U. S. 1,551,396, Aug. 25.

Electric arc and resistance furnace adapted for heat-treating metal articles, etc. A. D. KEENE. U. S. 1,557,062, Oct. 13.

Electric resistance furnace. F. THORNTON, JR. U. S. 1,557,104, Oct. 13.

Electric resistance furnace. A. M. MACFARLAND. U. S. 1,557,074, Oct. 13.

Induction electric furnace adapted for melting brass waste, etc. R. L. CHARTIER. U. S. 1,561,408, Nov. 10.

Electrolytic treatment of solutions from leucitic rocks. U. POMILIO and F. GIORDANI. U. S. 1,556,543, Oct. 6. Solns such as those obtained by treating leucitic rock with HCl or other acids are neutralized, and are then electrolyzed to remove Fe and prepare the soln. for pptn. of alumina by lime and subsequent fractional crystn. of K salts.

Circulation diaphragm electrolyzer for alkali chlorides. F. GIORDANI and U. POMILIO. U. S. 1,558,085, Oct. 20.

Apparatus for electrolytic production of iron. A. BOUCHER. U. S. 1,556,408, Oct. 6.

Continuous rotary electroplating apparatus. H. B. FARRAND. U. S. 1,557,474, Oct. 13.

Electrode for arc welding. C. J. HOLSLAG. U. S. 1,559,875, Nov. 3. A rod of metal is coated with Na silicate and lampblack which serve to control the action of the electrode on thin Fe or steel sheets to be welded. Asbestos, $CaCO_3$, B or Mg also may be used. Cf. C. A. 19, 1401.

5—PHOTOGRAPHY

C. E. K. MEES

Rongalit in photography. A. MILLER. *Phot. Ind.* 1925, 1064-5; *Brit. J. Phot.* 72, 602(1925).—A reducing agent, known as Rongalit C, used in the dye industry, has been found to act as a photographic developer. It is a combination of the Na salt of the unstable sulfoxylic acid and HCOH. When used with an excess of $NaHSO_3$ and KBr it works satisfactorily, but the substance very readily produces dichroic fog, has an initially slow rate of development, and decomposes after standing a few hours, becoming entirely inactive. A freshly prepd. mixt. of Rongalit C and $NaHSO_3$ may be used as a re-developer for brown tones on prints bleached in ferricyanide, but the soln. gives black tones if allowed to stand.

Silver in photography. LÜPPO-CRAMER. *Z. wiss. Phot.* 23, 294-302(1925).—This is a review of the literature of the question of the color and exact compn. and constitution of the developed Ag images in collodion and gelatin, of print-out images and of "dichroic" fog.

Reactions of silver sulfide. A. SREIGMANN. *Phot. Ind.* 1925, 541-2(1925).—Some reactions of Ag_2S in relation to toning are discussed. Ag_2S prints can be toned with

Au and by previous treatment with such a soln. as "Heliographontstuffer" the resulting tone can be varied from a red brown through purple brown to a Pt black. This depends on the ability of Ag_2S to act as a nucleus for the pptn. of certain non-metals as well as metals. Ag_2S images can also be transformed into colloidal Ag by means of a Ag intensifier, which also strengthens and darkens the image. M. L. DUNDON

Bleached-out pictures in silver iodide. LÜPPO-CRAMER. *Phot. Ind.* 1925, 650-1; cf. C. A. 19, 2918.—A fine-grained AgBr positive plate is given a uniform preliminary exposure, and then converted into AgI by bathing for 10 min. in Renwick's soln. which consists of 10 g. KI, 10 g. Na_2SO_4 , and 30 g. hypo, in 1 l. H_2O . It is washed 30 min. and dried. After the second exposure the plate is developed in alk. amidol of the following compn.: amidol, 5 g.; Na_2SO_4 , 50 g.; H_2O , 500 cc. This soln. is mixed with an equal vol. of 10% Na_2CO_3 or K_2CO_3 soln. immediately before using. Fixing is slow and should be carried out in 35% hypo at a temp. of 30-40°. Direct positives are obtained. The bleaching reaction is sensitized both optically and chemically by sensitizing and desensitizing dyes such as phenosafranine, pinakryptol green, erythrosin, and rhodamine B. On the other hand pinaflavol decreases sensitivity. The greatest effect was obtained by bathing the iodized plate for 1.5 min. in a soln. of the dye 1:10,000 contg. 1% KBr. M. L. DUNDON

Characteristics of photographic materials in the ultra-violet. G. R. HARRISON. *J. Opt. Soc. Am.* 11, 341-56 (1925).—The present methods of spectrophotometry require a knowledge of certain fundamental properties of photographic materials. In this investigation, the speed, the variation of contrast with wave length, and the variation of the exponent p in the Schwarzschild formula have been detd. in the spectral region from 435.0 to 214.4 μ . The radiation from a Hg vapor lamp or Cd spark was dispersed by a large aperture quartz monochromator, the spectral energy distribution being measured by a thermopile and d'Arsonval galvanometer. The rate of energy flux was altered by means of diaphragm and wire screens. No numerical values of speeds are given, the log speed-wave length curves show a small uniform increase in speed from 435 to 250 μ when the speed for all except the Schumann plate decreased very rapidly. The contrast was found to decrease from the visible into the ultra-violet. Some of the plates showed a min. at about 280 μ , reaching a small max. at about 250 μ followed by a very rapid decrease. Bathing the emulsions in certain oils was found to render them more suitable for photographic photometry in the ultra-violet. This treatment did not only increase the sensitivity but also produced a more uniform contrast with wave length. OTTO SANDVIK

Three-color prints by toning. J. C. ARCH. *Brit. J. Phot., Color Supp.* 19, 37-8 (1925).—Instructions are given for making 3-color prints by toning. The blue component is $\text{Fe}_4[\text{Fe}(\text{CN})_6]_3$; the green component is $\text{Cu}_2\text{Fe}(\text{CN})_6$; the yellow component is $\text{Pb}_2\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$. Bromide prints made from the three-color negatives are fastened to transparent supports, toned with soln. yielding the above colored salts, and finally assembled on a common base to form the color photograph. G. E. MATTHEWS

Theory and practice of fixing. II. ANON. *Phot. Ind.* 1925, 513-5 (1925).—The simple chemistry of fixation is outlined and typical formulas for acid and hardening fixing baths are given. The use of an indicator such as Aurin to show when a fixing bath becomes alk. is suggested. The useful life of a fixing bath is considered briefly as is also the necessity of thorough and suitable methods of washing. III. *Ibid* 542-6.—Methods of testing for hypo in wash H_2O are discussed, and several substances recommended for destroying hypo are mentioned. The accelerating action of hypo when added to developers, simultaneous development and fixation, development after fixation, and the reducing action of fixing baths are considered briefly. The recovery of Ag from used fixing baths is discussed. The hypo can be regenerated but not satisfactorily as the accumulation of NaBr eventually interferes with the usefulness of the soln. Substitutes for the hypo such as cyanide, etc., are mentioned. M. L. DUNDON

The ripening process. III. LÜPPO-CRAMER. *Z. wiss. Phot.* 23, 137-44 (1925); cf. C. A. 19, 1230.—L.-C. describes an expt. showing the protective action of either acid or basic dyes, against the NH_3 ripening of an unwashed Lippmann emulsion. He then contrasts the behavior of 2 chloro-bromide emulsions similarly prepd. with final excess of sol. bromide, but differing in that in the one case (A) the halides were added to the gelatin- AgNO_3 soln., while in the other (B) the AgNO_3 was added to the gelatin and halides. On heat treatment the latter emulsion was found at a certain point to be much (20° E. H.) more sensitive than the former. After further heating, B developed deep black, while A remained glass clear. Pure chloride emulsions showed a similar difference, in accordance with the order of mixing. No difference in grain size between A and B in either case could be definitely observed. L.-C. considers that the observed

photographic differences are explainable by the more considerable occlusion of gelatin, due to the conditions prevailing during pptn., in the crystals of *A* as compared with those of *B*. He offers explanations of the relatively greater diminution in sensitivity by such an agent as chromic acid, and of a heat-ripened as compared with the original emulsion, and likewise of one that has received a uniform moderate exposure to light, as compared with the unexposed emulsion. IV. *Ibid* 227-32. L.-C. describes an expt. illustrating the diminution in sensitivity by the action of chromic acid on a heat-ripened bromo-iodide emulsion, as compared with practically no action on the unripened emulsion. That the sensitivity of the ripened cannot be reduced as far as that of the unripened emulsion, he explains as due to the greater opacity of the former. He then discusses the theory of printing but and shows that an increase in grain size may be practically detrimental and describes the prepn. of an emulsion for a photometer paper. V. *Ibid* 286-94. L.-C. investigates and discusses the influence of variation in the excess of sol. bromide used, during mixing, on the facility of ripening, and the resulting contrast and speed of bromo-iodide gelatin emulsions. The effect of a large, as compared with a slight, excess of NH_4Br in the making of an ammoniacal bromo-iodide emulsion, was seen as a hastening of sensitivity, solarization, and fog, on ripening by keeping in a thermostat at 45° . The Ag halide grain, also, is both larger and more uniform. A similar excess of NH_4Br added to an emulsion newly mixed with but slight excess restrains ripening. When NH_4Br is replaced by its equivalent of KBr , the effects are similar but usually less pronounced. It is considered that the occlusion of gelatin is inhibited by the great adsorption of sol. bromide when the latter is in large excess in the pptn. medium. E. R. BULLOCK

"Ripening" of photographic emulsions from the standpoint of the doctrine of ion deformation. II. SCHMIDT. *Z. wiss. Phot.* 23, 201-16(1925).—Distinction is drawn between ripening during emulsification, and the ripening that is effected after washing. In the former, the sensitivity and absorption max. are observed to be slowly displaced in the direction of increasing wave length. It is supposed that under the influence of certain salts, NH_4 and gelatin, the lattice type of the individual grains is established at this stage. Adsorption forces, being a function of the structure and size of grain, are dependent on the nature of the ripening during emulsification, and this is thus considered to det. the intensity of the ripening after washing. The latter is regarded as a physico-chem. process which entails a progressive loss by the individual AgBr crystal lattices of their adsorbed Br ions, and consequently the alteration in the deformation forces in the interior of the grains, on which, it is considered, the observed large increase in general light-sensitivity depends. The latent fog that appears on over-ripening, or on continued storage, is attributed to a too great loss of Br ions, leading to excessive deformation and changes in the grain that are equivalent to an exposure to light. In the case of an emulsion prep'd. with excess Ag salt instead of with excess halide, there is observed on emulsification an increased general sensitivity and also an extension in the direction of increasing wave length, but such an emulsion fogs under attempted after-washing ripening treatment; this, it is shown, is in harmony with S.'s theory. E. R. BULLOCK

Suggested method of exposing H. and D. strips. T. THORNE-BAKER and W. A. BALMAIN. *Brit. J. Phot.* 72, 624(1925).—The authors suggest a method of making an H. and D. detn. which involves the use of an enamel contg. RaBr_2 coated in increasing quantities, as x g., $2x$ g., etc. The strip is placed in contact with the photographic plate for a predetd. time. The gamma radiation is the active exposing source and the alpha and beta radiation are screened off. No mechanism is necessary and the exposure is non-intermittent. G. E. MATTHEWS

Developable glass etchings. G. KÖGEL. *Phot. Ind.* 1925, 679-80.—If a gelatin Ag or dichromate image is removed completely from a glass plate and the plate treated with ammonium bifluoride soln. sometimes an etched picture which is a copy of the original picture appears on the glass. K. speculates as to whether this latent effect may be chem. or phys. It is probably related to the Limmer process for photo-etching of clock faces. M. L. DUNDON

Enlargements. G. COLLIN. *Rev. franc. phot.* 6, 277-9(1925).—For local brush development of enlargements a diaminophenol developer is recommended in combination with a retarding bath of NaHSO_3 liquor, 5 cc.; KBr , 10%, 5 cc.; H_2O to make 100 cc. The print is first immersed in the developer until the image appears. It is then quickly rinsed and placed in the retarding bath. Development is finished by local brushing. O. COOK

Color photography. W. V. D. KELLEY and D. TRONOLONE. U. S. 1,561,168,

Nov. 10. A latent image is formed in a colloid layer, developed in neutral or acid diaminophenol soln., toned with an Fe salt and, after clearing with a bath of NH_4Br and $\text{K}_2\text{Cr}_2\text{O}_7$ in H_2O , an image toned with a U salt is formed in the same colloid layer in registry.

Color photography. L. E. TAYLOR. U. S. 1,560,437, Nov. 3. A soln. of CuSO_4 , H_2O_2 and an acid, e. g., H_2SO_4 , in H_2O , is used for etching out the exposed portions of an exposed and developed film, preliminary to coloring of different films for superposing in register. U. S. 1,560,438 relates to mech. features of coloring motion picture films.

Photographic sensitizer. E. E. JELLEY. U. S. 1,560,240, Nov. 3. See Brit. 229,566 (C. A. 19, 3069).

Composition for cementing and coating photographic films. V. L. FARRINGTON and E. T. ALDERMAN. U. S. 1,556,512, Oct. 6. Nitrocellulose 4, acetone 8, ether 1-4, AmOAc 2-8 and alc. 4-8 parts.

Apparatus for dyeing photographic films. J. G. CAPSTAFF. U. S. 1,560,541, Nov. 10.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Chloroferriate substituted ammonium bases; a contribution to coordination chemistry. H. REMY. *Ber.* 58B, 1565-71 (1925).—On the basis of the coordination theory the compds. $\text{M}_2^1(\text{FeX}_6)$ and $\text{M}_4^1(\text{FeX}_7)$ should exist. The following were prepd.: *Methylammonium tetra-chloroferriate*, $(\text{CH}_3\text{NH}_2)(\text{FeCl}_4)$, m. 211° , green-yellow powder. *Methylammonium hepta-chlorohemi-aquoferriate*, $(\text{CH}_3\text{NH}_2)_4(\text{FeCl}_7 + \text{H}_2\text{O})$, orange prisms, m. 161° . *Dimethylammonium tetra-chloroferriate*, $[(\text{CH}_3)_2\text{NH}_2](\text{FeCl}_4)$, green powder, m. $97-104^\circ$. *Dimethylammonium penta-chloroferriate*, $[(\text{CH}_3)_2\text{NH}_2]_2(\text{FeCl}_5)$, yellow-green crystals, m. 98° . *Dimethylammonium hepta-chloroferriate*, $[(\text{CH}_3)_2\text{NH}_2]_2(\text{FeCl}_6)$, dark red crystals, m. 48° . *Trimethylammonium tetra-chloroferriate*, $[(\text{CH}_3)_3\text{NH}](\text{FeCl}_4)$, m. p. not detd. *Trimethylammonium penta-chloroferriate*, $[(\text{CH}_3)_3\text{NH}]_2(\text{FeCl}_5)$, green needles, m. 143.5° . *Tetramethylammonium tetra-chloroferriate*, $((\text{CH}_3)_4\text{N})(\text{FeCl}_4)$, apple-green crystals, m. 308° . *Ethylammonium tetra-chloroferriate*, $(\text{C}_2\text{H}_5\text{NH}_2)(\text{FeCl}_4)$, yellow-green crystals, m. 85° . *Ethylammonium hepta-chloroferriate*, $(\text{C}_2\text{H}_5\text{NH}_2)_2(\text{FeCl}_6)$, orange needles, m. 117° . *Propylammonium tetra-chloroferriate*, $(\text{C}_3\text{H}_7\text{NH}_2)(\text{FeCl}_4)$, black to green crystals, m. p. not detd. *Propylammonium hepta-chloroferriate*, $(\text{C}_3\text{H}_7\text{NH}_2)_2(\text{FeCl}_6)$, orange crystals, softens 110° , m. 118° . *Butylammonium tetra-chloroferriate*, $(\text{C}_4\text{H}_9\text{NH}_2)(\text{FeCl}_4)$, greenish brown crystals, m. 60.5° .

ROSALIE COBB

Constitution of the thionic acids. ISRAEL VOGEL. *J. Chem. Soc.* 127, 2248-9 (1925).—In the study of $(\text{S}_2\text{O}_3)_x$ (V. and Partington, C. A. 19, 2919) it became evident that none of the formulas proposed gave a rational explanation of the exptl. facts recorded. The following formulas are proposed: dithionic acid, $\text{HO}_2\text{S}\cdot\text{SO}_2\cdot\text{OH}$; trithionic acid, $\text{S}(\text{SO}_2\cdot\text{OH})_2$; tetrathionic acid, $\text{S}:\text{S}(\text{SO}_2\cdot\text{OH})_2$; pentathionic acid, $\text{S}:\text{S}:\text{S}(\text{SO}_2\cdot\text{OH})_2$; various exptl. facts are reviewed, with which these formulas are in agreement.

C. J. WEST

Is orthoboric acid volatile with steam? RICHARD ANSCHÜTZ AND KARL RIEFENKRÖGER. *Ber.* 58B, 1734-5 (1925).—Distg. off one-half of a H_3BO_3 soln. at atm. and reduced pressures gave no trace of acid in the distillate, nor loss of acid in the residue. When H_3BO_3 was heated under pressure to $150-180^\circ$ and then distd. at atm. pressure, about 90% of the acid distd. over. H_3BO_3 is not volatile with steam; the $\text{O}:\text{B}:\text{OH}$ formed at higher temps. is volatile with steam.

ROSALIE COBB

Some properties of stannous iodide. P. FREUNDLER AND MILE Y. LAURENT. *Bull. soc. chim.* 37, 1133-5 (1925); cf. C. A. 19, 780.—(1) SnCl_2 and NaI do not form a complex; the monohydrate, $\text{SnI}_2\cdot\text{H}_2\text{O}$, is obtained upon mixing cold concd. solns. This hydrate is stable in the cold but completely hydrolyzed by cold water or transformed by desiccation in the cold to anhyd. SnI_2 . (2) SnCl_2 and KI form yellow needles of $\text{SnI}_2\cdot 2\text{KI}\cdot 3\text{H}_2\text{O}$ in neutral soln., and in cold (22°), warm (45°), and hot acid solns., $\text{SnCl}_2\cdot 2\text{KI}\cdot \text{HCl}$, $\text{SnCl}_2\cdot 3\text{KI}\cdot \text{HCl}$, and anhyd. SnI_2 , resp., are formed. The transformations are reversible. The K complex is stable in neutral soln. but oxidizes in acid soln., especially in sunlight, to a deep brown soln. contg. a periodide. P. B. PLACE

Working-up noble-metal alloys, filings, turnings, etc., in the laboratory or on a small scale. F. W. STEINMETZ. *Chem.-Ztg.* 49, 807 (1925).—Inquartation, granulation, digestion with 36°Bé. HNO_3 , followed by washing, diluting, decanting or filtering,

and then washing, separate Au-Pt residues from Ag soln. The Ag soln. is pptd. with dil. HCl; the washed AgCl is then reduced with Zn strips and HCl, the Ag washed, dried and fused in graphite crucibles. The Au-Pt residue is dissolved in *aqua regia*, dild., and pptd. with SO_2 or FeSO_4 . If Pt be present, the filtrate from AgCl is evapd. with HCl, dild., pptd. with NH_4Cl , filtered and ignited. W. C. EBAUGH

7--ANALYTICAL CHEMISTRY

WILLIAM T. HALL

The use of liquid amalgam in volumetric analysis. III. Determination of phosphoric acid with the aid of lead amalgam. KINICHI SOMEYA. *Z. anorg. allgem. Chem.* 148, 58-64 (1925).—Ppt. NH_4 phosphomolybdate in the usual way and wash the ppt twice by decantation with a soln. of NH_4HSO_4 contg. 25 cc. H_2SO_4 and 15 cc. of concd. NH_4OH per liter. Filter into a Munroe crucible and dissolve in a little hot NH_4OH . Evap. to small vol. in an Erlenmeyer flask, add 50 cc. of concd. HCl, reduce with Pb-Hg, and titrate the reduced soln. with 0.1 *N* KMnO_4 . The results given appear to be remarkably accurate. W. T. H.

Stability of sodium thiosulfate solutions. E. COLLARD, JR. *Ann. chim. anal. chim. appl.* 7, 291-2 (1925).—A standard soln. was found to have the same titer after standing $3\frac{1}{2}$ years. W. T. H.

Evaluation of barium dioxide. E. C. WAGNER. *Ind. Eng. Chem.* 17, 972-4 (1925).—Treat 0.25 g. of sample with 50 cc. of water and 200 cc. of 0.25 *N* HCl contg. 8.5 g. H_3PO_4 and 0.1 g. MnCl_2 crystals per l and not with concd. H_3PO_4 as stated in *C. A.* 19, 2921. The method gives results consistently higher than those by the KMnO_4 method as ordinarily carried out. W. T. H.

Detection of oxygen. HANS SCHMALFUSS AND HANS WERNER. *J. prakt. Chem.* 111, 62-4 (1925); cf. *C. A.* 19, 1110. It is sometimes desirable to detect small quantities of O_2 in gases. A procedure has been developed which permits the detection of 0.002 cc. of O_2 in 200 cc. of a gas mixt. The test depends upon the fact that a piece of filter paper moistened with a drop 1% diphenylamine in 18 *N* H_2SO_4 , and treated with NO becomes blue in the presence of O_2 . Instead of diphenylamine in H_2SO_4 a soln. of α -naphthylamine in dil. AcOH can be used. In the reaction vessel, a little water is placed and a strip of paper is annexed to the dry wall of the vessel with the aid of a rod which has been touched with the reagent. After evacuating the vessel, a little O_2 -free NO is introduced and then the gas to be tested. W. T. H.

Electrometric studies of the precipitation of hydroxides. I. Precipitation of magnesium, manganous, ferrous, cobalt, nickel and thorium hydroxides by use of the hydrogen electrode. HUBERT THOMAS STANLEY BRITTON. *J. Chem. Soc.* 127, 2110-20 (1925).—The various methods which have hitherto been used for the detn. of the basic strength of the hydroxides have not always led to consistent results. In this investigation the order of pptn. was studied by gradually adding dil. alkali hydroxide and measuring the e. m. f. when pptn. took place, with the aid of the H_2 electrode. The order of pptn. was as follows; $\text{Mg}(\text{OH})_2$ at $p_{\text{H}} = 10.4$; $\text{Mn}(\text{OH})_2$ at $p_{\text{H}} = 8.4$; $\text{Co}(\text{OH})_2$ at $p_{\text{H}} = 6.8$; $\text{Ni}(\text{OH})_2$ at $p_{\text{H}} = 6.6$ and $\text{Fe}(\text{OH})_2$ at $p_{\text{H}} = 5.5$. In every case the ppt. contained an appreciable amt. of the original anion of the salt used. These p_{H} values are practically independent of the nature of the anion present and of the precipitant and are affected but slightly by changes in concn. of the metal salts in dil. solns. which have to be attained before any particular hydroxide can ppt. The dependence of these values on the soly. products of the different hydroxides is shown mathematically and it is demonstrated anew that the real reason why NH_4 salt prevents the pptn. of $\text{Mg}(\text{OH})_2$ and $\text{Mn}(\text{OH})_2$ by NH_3 soln. is due to the inability of such a soln. to furnish enough OH^- ions to cause pptn. when sufficient NH_4 salt is present. II. **The precipitation of the hydroxides of zinc, chromium, beryllium aluminium, bivalent tin and zirconium by use of the hydrogen electrode and their alleged amphoteric nature.** *Ibid.* 2120-41 (1925).— $\text{Al}(\text{OH})_3$ begins to ppt. at $p_{\text{H}} = 4.1$; $\text{Be}(\text{OH})_2$ at $p_{\text{H}} = 5.7$; $\text{Zn}(\text{OH})_2$ at $p_{\text{H}} = 5.2$; $\text{Cr}(\text{OH})_3$ at $p_{\text{H}} = 5.35$; $\text{Sn}(\text{OH})_2$ at $p_{\text{H}} = 1.9$ and $\text{Zr}(\text{OH})_4$ at $p_{\text{H}} = 2.8$. In all cases basic salts, rather than pure hydroxides, are pptd. Of all these bases, $\text{Al}(\text{OH})_3$ appears to be the only one which is definitely amphoteric, uniting with one mol. of NaOH, for example, to form NaAlO_2 . Although Hildebrand obtained data indicating similar salt formation with $\text{Zn}(\text{OH})_2$ and $\text{Zr}(\text{OH})_4$, these observations could not be confirmed. In the case of Cr, it would appear that the green modification of the sulfate is due to the hydrolysis of the violet salt and the $\text{Cr}(\text{OH})_3$

bound to colloidal aggregates of basic salt loses its reactivity. The fact that BaCl_2 and AgNO_3 produce incomplete pptn. in the case of the green sulfate and chloride is probably accounted for in the same way that Cl^- in Fe_2O_3 hydrosols is incompletely pptd. by Ag^+ . The Werner coordination theory does not offer as good an explanation of the anomalous behavior of green and violet Cr salts and it is pointed out that the original evidence of Werner and Gubser is unconvincing although Lamb and Fonda (C. A. 15, 2375) have stated that it is the most striking exemplification of the Werner theory of molecular structure. The study of ZrCl_4 and $\text{Zr}(\text{SO}_4)_2$ revealed the fact that both salts in soln. are composed of highly dispersed basic particles and hydrolyzed acid, there being no evidence of the so-called "zirconyl" radical. III. **Precipitation in the cerite group of rare earths and of yttrium hydroxide** by the use of the hydrogen electrode. *Ibid* 2142-7(1925).—In this group, the pptn. of hydroxide, or basic salts, begins at the following p_{H} values: $\text{Yt}(\text{OH})_3$ at 6.78; $\text{Sa}(\text{OH})_3$ at 6.83; $\text{Nd}(\text{OH})_3$ at 7.00; $\text{Pr}(\text{OH})_3$ at 7.05; $\text{Ce}(\text{OH})_3$ at 7.41; $\text{La}(\text{OH})_3$ at 8.35. All these values lie below those of $\text{Mg}(\text{OH})_2$ and $\text{Mn}(\text{OH})_2$ and above that of $\text{Zn}(\text{OH})_2$. The difference between the hydron concn. for the pptn. of $\text{Th}(\text{OH})_4$ and those of the rare earth hydroxides accounts for some of the methods used in sepn. Th from these earths. If sufficient NH_4Cl is present, the pptn. of La and Ce⁺⁺⁺ hydroxides is prevented. IV. **Precipitation of mercuric, cadmium, lead, silver, cupric, uranic and ferric hydroxides** by use of the oxygen electrode. *Ibid* 2148-59(1925).—Although O_2 electrodes cannot be used to det. accurately the changes in hydron concn., they are sufficiently responsive to indicate the character of the changes and to give an approx. idea of the hydron concn. According to the results described in this paper, together with the results of the work with the H_2 electrode, the following table gives the metals in the order of the hydron concns. at which their respective hydroxides or basic salts are pptd. from dil. solns. Although it is not certain that this order represents the actual basic strength of the hydroxides, it can be said that these hydron concns. underlie many of the reactions of the various sepn. which are used in analytical chemistry.

Hydron concn.	Metal ion.
10^{-11}	Mg
10^{-9}	Ag, Mn^{++} , La, Hg^{++}
10^{-8}	Ce ⁺⁺⁺ , Co, Ni, Cd, Pr, Ne, Yt, Sa, $\text{Fe}^{++}(?)$, Pb?
10^{-6}	Zn, Be, Cu, Cr,
10^{-5}	Al,
10^{-4}	U, Th,
10^{-3}	Sn^{++} , Zr, Fe^{+++}

According to this, $\text{Al}(\text{OH})_3$ is a very weak base yet Al occurs higher than Cr in the e. m. f. table. Heyrovsky's system of classification indicates that $\text{Pb}(\text{OH})_2$ is stronger than $\text{Mg}(\text{OH})_2$ and that HgO is weaker than $\text{Zn}(\text{OH})_2$ but the above values indicate that the contrary is true, which would seem more reasonable. The ppt. obtained by adding NaOH to $\text{UO}_2(\text{NO}_3)_2$ soln. was chiefly hydroxide and not $\text{Na}_2\text{U}_2\text{O}_7$ as often stated. Significant changes in color were observed in the titration of uranyl and ferric salts which can be best explained by the colloid theory. W. T. H.

The separation of palladium from platinum. F. KRAUSS AND H. DENEKE. Z. anal. Chem. 67, 86-96(1925).—Several methods for the detn. of Pd and Pt in mixts of their pure salts were tested. The attempt to dissolve out the Pd by means of hot HNO_3 or hot HCl proved unsuccessful. The pptn. of Pd with α -nitroso- β -naphthol can be carried out successfully but the Pd ppt. is very voluminous. The same is true of the ppt. of Pd by means of C_2H_2 and when considerable Pd is present it is difficult to get quant. pptn. The sepn. with dimethylglyoxime has several disadvantages although the expts. show that with a modified procedure it is possible to obtain excellent results. The sepn. with $\text{Hg}(\text{CN})_2$ is capable of yielding excellent results but the reagent is poisonous and expensive to use. Of all the methods tried, the following is preferred in the case of a mixt. of only Pd and Pt. Evap. the soln. several times to dryness with HCl to remove any HNO_3 . Take up the residue in HCl , add an excess of NH_4Cl and evap. again to dryness. Take up the residue with a little water and add some more of a cold. satd. NH_4Cl soln. After a short time, filter off the $(\text{NH}_4)_2\text{PtCl}_6$ and wash with a satd. NH_4Cl soln., until the filtrate is colorless, and then with 96% alc., dissolve the ppt. in hot water and ppt. Pt by adding $\text{N HCO}_2\text{Na}$. Filter off, ignite in H_2 and weigh the Pt. Neutralize the first filtrate with Na_2CO_3 , treat with HCO_2Na and wash the Pd sponge very carefully with hot water. Ignite as with Pt. W. T. H.

The determination of traces of lead in organics and the changes that take place in

very dilute aqueous solutions of lead nitrate. HUGO BERNHARDT. *Z. anal. Chem.* **67**, 97-105(1925).—The method consists in first destroying the org. matter by means of eucblorine or an oxidizing fusion, then pptg. PbS, oxidizing and dissolving it, depositing PbO, electrolytically, dissolving the ppt. in an acid soln. of KI and titrating the liberated I_2 . Before pptg. PbS, it is necessary to add 50 cc. of 10% NH_4 citrate to prevent carrying down phosphates in the nearly neutral soln. It is well to dissolve the PbS ppt. and repeat the pptn. in the analysis of bones. For the electrolysis, a rotating gauze anode is recommended. The soln. should be dild. to about 250 cc. treated with 10 cc. of 60% HNO_3 and electrolyzed with a current of 0.2-0.3 amp. at 2.8-3.2 vs. In work with solns. of $Pb(NO_3)_2$ contg. 10 mg. Pb per cc., it was found that the Pb content diminished as the soln. was allowed to stand in a glass vessel owing to the formation of Pb silicate on the walls of the vessel. W. T. H.

The determination of traces of mercury. I. The sensitivity of the qualitative tests for mercury. A new method for the detection of mercury sensitive to one part in a billion. H. S. BOOTH AND NORA E. SCHREIBER. *J. Am. Chem. Soc.* **47**, 2625-9 (1925).—Some 18 sensitive tests for Hg were studied and greater delicacy was obtained with a new electrolytic test. Place a drop of the soln. on a microscope slide, make acid with HNO_3 , touch with a polished Cu cathode and insert a Pt anode. Pass a current of 1.3-1.5 milliamp. at 1.5-2 v. through the soln. and after 2-3 min. exam the tip of the Cu anode under the microscope. W. T. H.

Detection of gold formed from mercury. H. STAMMREICH. *Z. anorg. allgem. Chem.* **148**, 93-6(1925).—If Hg is distd. *in vacuo* at a low temp., overheating being avoided at the last, all lower-boiling metals are left behind, as has been proved in the case of Pb, Bi, Cd, Na, etc. After treating the last drop of the distn. residue with pure HNO_3 , the Hg will dissolve, leaving the Au behind. Under the microscope the diam. of the residual Au is about 2.3 that of Au in its usual solid condition. If the Au is obtained in Hg which is so highly dispersed that it will not collect to form a liquid, it is desirable to dissolve the Au in HNO_3 with a very little HCl and from the soln. ppt. Au with hydrazine in ammoniacal soln. Owing to the highly absorptive nature of finely dispersed Hg, it is permissible to reject the liquid Hg when both liquid and colloidal Hg are present. A further difficulty arises from the fact that Cu and Fe interfere somewhat with the detection of small quantities of Au. Sometimes shaking with $Hg(NO_3)_2$ helps, but if only traces of Au are present, it is best to dissolve in a little *aqua regia*, ppt. Au with hydrazine and NH_4OH and remove the $Fe(OH)_3$ by the addn. of a little HCl. W. T. H.

The determination of uranium. G. E. F. LUNDELL AND H. B. KNOWLES. *J. Am. Chem. Soc.* **47**, 2637-44(1925).—Contrary to prevailing prejudices, the volumetric method for detg. U is accurate provided a cool, acid soln. is passed through a Jones' reductor and sufficient time is allowed for atmospheric oxidation before titration with $KMnO_4$. The reduction is then to the quadrivalent state. The soln. should contain 1% or less of U and 5% of H_2SO_4 . Similarly the gravimetric method of pptg. with NH_4OH and weighing as U_3O_8 is accurate but it is advisable to add macerated paper pulp; there is no need for special ignition in H_2 or in O_2 . A residue of U_3O_8 can easily be tested volumetrically by titrating with $KMnO_4$ after dissolving in HF and H_2SO_4 and adding boric acid. W. T. H.

The development of organic elementary analysis from Lavoisier to Pregl. C. WEYGAND. *Z. angew. Chem.* **38**, 881-5(1925). B. H.

Azido-dithiocarbonic acid. II. Methods for the determination of the azido-dithiocarbonate radical, $SCSN_2$. A. W. BROWNE AND G. B. L. SMITH. *J. Am. Chem. Soc.* **47**, 2698-702(1925).—Several possible methods for detg. $SCSN_2$ are discussed: (1) titration of the free acid with methyl red as indicator, (2) gravimetric detn. as the Ag salt or as $AgCl$ equiv. to it, (3) titration with $AgNO_3$ as in the Gay-Lussac or Volhard methods for titrating Cl^- and (4) titration with I_2 dissolved in alc. Of these, apparently the Volhard titration method is to be preferred. W. T. H.

A new method of precipitating oxalic acid in the systematic qualitative procedure by means of basic bismuth nitrate. A. KESCHAN. *Z. anal. Chem.* **67**, 81-6(1925).—Oxalic acid, as well as H_3PO_4 , can be removed by pptn. with Bi subnitrate (3 g. subnitrate for 0.88 g. of $C_2O_4^{--}$), in a soln. which is not over 2 N in HNO_3 . Owing to the formation of oxalate complexes, trivalent Fe, Cr and Al interfere somewhat. In dil. soln. Al does no harm and Fe can be easily reduced to the bivalent state by means of $NH_4NH_2.HCl$ or H_2S . With Cr, difficulty is encountered both with respect to the removal of the Cr and of the C_2O_4 anion. By adding 1-2 cc. of N $(NH_4)_2HPO_4$ and boiling with $BiONO_3$ first the oxalate and then the phosphate is pptd. In the absence of Cr and Fe, evap. the filtrate from the 2nd group to a small vol., add a little concd.

HNO₃ and again evap. to small vol., add the necessary amt. of BiONO₃ and dil. with 10–15 vols. of water. Boil a few minutes, dilute with an equal vol. of hot water, allow to cool somewhat and filter while still warm. W. T. H.

Absorption of O and liberation of CO by alkaline pyrogallol solutions (DRAKELEY, NICOL.) 2. Determination of CO in blood and in air (SAVERS, YANT) 11B. Gasometric CaC₂ method for the determination of moisture (JAKOWENKO) 12.

Gas analysis. J. R. CATN. U. S. 1,560,660, Nov. 10. In-letg. C in steel, rubber or CO₂ in carbonates, flue gases, etc., an aq. soln. of Ba(OH)₂ or other suitable electrolyte is used for absorbing CO₂ and changes in elec. resistance of the electrolyte due to the absorption are noted to det. from them the amt. of CO₂ absorbed.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

An X-ray investigation of some finely divided minerals, artificial products, and dense rocks. F. RINNE. *Z. Krist.* 60, 55–69 (1924).—The X-ray diffraction patterns are described (but not analyzed) for: bauxite, hydargillite, diasporite, Al₂O₃, Fe₂O₃, SiO₂, opal, V₂O₅, kaolin, allophane, talc, serpentine, meerschaum, calcite, aragonite (flos-ferri), vaterite, magnesite, hydrozincite, turquoise, boracite, stassfurtite, org. compds. such as asphalt, ozocerite, and dopplerte, and rocks, such as limestone, flint, obsidian, etc.

Beryllium oxide as a mineral, and its crystal structure. G. AMINOFF. *Z. Krist.* 62, 113–22 (1925).—An analysis of an unknown mineral from Långban gave 98% BeO. Properties: dibexagonal pyramidal (isomorphous with ZnO) $c = 1.6288$, hardness 9, uniaxial +, $\epsilon = 1.733$, $\omega = 1.719$. It is named *bromellite*, after the Swedish mineralogist von Bromell. The structure found by McKeehan (*C. A.* 17, 1356) on artificial BeO is verified—ZnO type, $c = 4.36$ Å U and $a = 2.68$ Å U.

Chromite from Mont Djéti, near Atakpame, Togo. M. H. ARSANDAUX. *Bull. soc. franç. minéral.* 48, 70–6 (1925).—The high Al and Mg content places this mineral intermediate between spinel and chromite.

Vaterite and μ -calcium carbonate. R. E. GIBSON, R. W. G. WYCKOFF AND H. E. MERWIN. *Am. J. Sci.* 10, 325–33 (1925).—A critical examn. of the literature on "vaterite" has shown that this name has been applied to 2 entirely different spherulitic habits of CaCO₃. The first of these, which was studied by Vater and later by Johnston, Merwin and Williamson, has now been shown by X-ray powder photographs definitely to be calcite. The second which was studied by Butschli, Spangenberg, Rinne and Heide has been proved to be essentially μ -CaCO₃. A reliable method for the prepn. of crystals of CaCO₃ in fairly large yields has been obtained. From a review of all of the work in this field it may be stated that anhyd. CaCO₃ may exist at ordinary temp. and pressure in 3 distinct cryst. forms, calcite, aragonite and μ -CaCO₃.

The chemical constitution of the monoclinic pyroxenes and amphiboles. B. GOSSNER. *Z. Krist.* 60, 76–124 (1924). The chemical composition of alkali amphiboles. *Ibid.* 302–10 (1924); cf. *C. A.* 19, 952.—The compns. are shown to correspond to combinations in varying proportions of certain simple mols.

The chemical composition of crossite, arfvedsonite, aenigmatite, rhoenite and babingtonite. B. GOSSNER. *Z. Krist.* 61, 538–44 (1925); cf. *C. A.* 19, 952.—Analyses are interpreted to show the relationship of these minerals to the more common members of the amphibole and pyroxene groups.

The FeSiO₃-CaSiO₃-MgSiO₃-NaFeSi₂O₆ system of monoclinic amphiboles. A. N. WINCHELL. *Am. Mineral.* 10, 335–41 (1925).—By plotting the chem. compn. of the minerals of the grunerite-cummingtonite-kupferite series against the optical constants, the influence of each mol. on the optical properties is shown. NaFeSi₂O₆ produces the greatest effect.

Leverrierite as a schist-forming mineral. C. S. CORBETT. *Am. J. Sci.* 10, 247–68 (1925).—Chem. analyses and phys. properties of the hydrous Al silicate, leverrierite show it to be a mineral differing from muscovite chiefly in the fact that K is not essential to its compn. It is the type mineral of a group which includes batchelorite, kryptotile, rectorite, delanouite and pyrophyllite. The similarity in compn. and properties of muscovite and leverrierite suggest that the latter may occur in every situation where

the former is found as a mineral of secondary development, especially in schistose rocks. The distinction between muscovite and leverrierite is not possible by ordinary petrographic or optical methods, nor by microchem. tests in samples which contain an appreciable amt. of K. The specimen giving the most conclusive evidence of the presence of leverrierite by optical and microchem. examn. gave also the best result upon X-ray analysis, and furnishes evidence of the development of this mineral under conditions of anamorphism producing schistose rocks. L. W. RIGGS

Hedyphane from Franklin Furnace, New Jersey. Wm F. FOSHAG AND R. B. GAGE. *Am. Mineral.* 10, 351-3 (1925).—The analysis: Cl 2.98, As_2O_3 29.94, PbO 52.77, (Mn,Fe)O 0.28, CaO 14.98, MgO 0.10, ZnO 0.23, H_2O 0.08%, establishes hedyphane as a new species. Its $\omega = 2.026$, $\epsilon = 2.010$. C. B. SLAWSON

New investigations upon dewindtite: birefringence, chemical composition, and dehydration; comparison with dumontite. ALFRED SCHOEP. *Bull. soc. franç. mineral.* 48, 77-85 (1925).—The crystals are biaxial +, 2H large, and extinction perpendicular. H_2O 7.93, P_2O_5 10.14, UO_3 54.80, PbO 24.85%. C. B. SLAWSON

A new mineral from Långban. G. AMINOFF. *Z. Krist.* 60, 262-74 (1924). The compn. is: Sb_2O_3 54.17, P_2O_5 0.23, Al_2O_3 34.72, CaO 0.94, MgO 0.52, Na_2O 8.50, K_2O 0.21, H_2O 0.39 = 99.68%, corresponding to the formula $Na_2O.2Al_2O_3.Sb_2O_3$. Crystals are hexagonal, with $c = 1.6309$. Uniaxial, negative, ω 1.7724, ϵ 1.7700. This mineral is named *swedenborgite*, in honor of Emanuel Swedenborg. L. S. RAMSDELL

The genesis of the Texada Island magnetite deposits. C. O. SWANSON. Can. Bur. Mines, *Summary Rept.* 1924A, 106-44.—The probable conditions under which Fe_3O_4 was deposited from magmatic solns. are described. L. W. RIGGS

The copper deposits of Capillitas, Patamarea, Argentine. E. KITTL. *Z. prakt. Geol.* 8, 121-4; 9, 140-6 (1925).—The ore deposit is associated with andesite. Primary minerals present are: pyrite, arsenopyrite, chalcopyrite, quartz, kaolin, galena, sphalerite, barite, and tetrahedrite. Minerals formed in the cementation zone are: chalcopyrite, enargite, tetrahedrite, chalcocite, bornite, covellite, pyrite. In the oxidation zone: cerussite, rhodochrosite, native Cu, cuprite, malachite, Au, braunite, limonite, linarite, and $CuSO_4$. W. H. NEWHOUSE

Upper Beaver river area, Mayo district, Yukon. W. E. COCKFIELD. Can. Bur. Mines, *Summary Rept.* 1924A, 1-18.—Deposits of galena with smaller quantities of tetrahedrite and Zn blende are found at McKay hill, Silver hill and Grey Copper hill. These ores generally carry small quantities of Ag. The outlook for profitable mining is unfavorable. L. W. RIGGS

Driftwood Creek map-area, Babine Mts., British Columbia. GEORGE HANSON. Can. Dept. Mines, *Summary Rept.* 1924A, 19-37.—Twelve mining properties are described which show Ag, Pb and small quantities of Au. The deposits are small and discontinuous. Prince Rupert to Burns Lake, B. C. *Ibid* 38-43.—The common minerals contg. Cu, Pb, Zn, Ag, Fe and As are found, also Au ores, but none of them in quantities sufficient to encourage com. development. L. W. RIGGS

Tungsten deposits near Hazelton, B. C. M. E. HURST. Can. Dept. Mines, *Summary Rept.* 1924A, 44-6.—W has been found in 2 claims. L. W. RIGGS

Chilko Lake and vicinity, B. C. V. DOLMAGE. Can. Bur. Mines, *Summary Rept.* 1924A, 59-75.—Au, Ag, Sb and As are found in the Morris mine and in other claims. The ores are low grade. L. W. RIGGS

Pemberton area, Lillooet district, B. C. C. E. CAIRNES. Can. Dept. Mines, *Summary Rept.* 1924A, 76-99.—About 12 mining properties are described, most of which show low Au, Ag and Cu values. Zn and Pb ores are less common. Nickeliferous mineral deposit, Emory Creek, Yale mining division, B. C. *Ibid* 100-5.—The genesis of the Ni deposits and particularly of *pentlandite* is described at length. L. W. RIGGS

Genesis of lithium pegmatites. W. T. SCHALLER. *Am. J. Sci.* 10, 269-79 (1925).—The Li pegmatites as now seen are not the result of an original crystn. of a magma unusually rich in the so-called mineralizers, but the results of later replacement (probably hydrothermal) of an earlier formed rock essentially free from any of the mineralizers. The earlier formed rock in the California field was graphic granite whose peculiar structure and texture served as a key in the interpretation of subsequent rock replacements. L. W. RIGGS

A pigeonite-andesite with diabasic texture from Taodeni, Soudan, Sahara, and the origin of bowlingite from the same locality. M. E. DENAEYER. *Bull. soc. franç. mineral.* 47, 355-7 (1924).—Bowlingite is an alteration product of pigeonite which has an extremely low Ca content. C. B. SLAWSON

Lower muds (older loess) of the vicinity of Paris. AGAFONOV AND MILE. MALICHEF. *Compt. rend.* 181, 300-2 (1925), cf. C. A. 18, 1027.—These muds are much less

changed, less calcareous, more heterogeneous and coarser than the recently deposited muds of the locality. The probable genesis is described. L. W. RIGGS

A new attempt to determine the relative dissemination of the rare elements. G. BERG. *Z. prakt. Geol.* 5, 73-9 (1925).—Discussion of the abundance of each of the elements is followed by a table with the elements listed. W. H. NEWHOUSE

Measurement of the altitude of the ozone layer in the atmosphere. J. CABANNES AND J. DUFAY. *Compt. rend.* 181, 302-4 (1925).—Mathematical calcs. applied to data furnished by photospectroscopic observation upon the absorption of the sun's rays gave about 50 km. as the height of the ozone layer. L. W. RIGGS

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST AND R. S. WILLIAMS

The Hornsey low-temperature process for reducing iron ore. G. HOOGHWINKEL. *Iron Coal Trades Rev.* 111, 326 (1925).—The Hornsey app. consists of 3 rotary furnaces arranged in series. Ore is fed into the upper one, where it is heated to 800° by the surplus gas from the second retort. The ore drops by gravity into the second retort where it is mixed with low-grade coal or other reducing agent. This retort is heated by an auxiliary heating system. In the third retort, the charge is cooled by H₂O sprays to a temp. where reoxidation will not occur. From here it is discharged through an air-tight opening. The retorts are operated at different speeds and at temps. never above 1050°. Fe in the final product is separated magnetically from the gang and is 98-99.5% pure. Ores ranging between 63.4 and 21.0% Fe were used. Steel made from the granular Fe without further additions is of a superior quality. J. F. B.

Notes on blast furnace slags. R. R. F. WALTON. *Iron Coal Trades Rev.* 111, 319 (1925).—The roles of SiO₂, Al₂O₃, CaO, MgS and CaS are discussed. J. F. BYRNE

Dimensions and output of German open-hearth furnaces. HUGO BONSEN. *Iron Coal Trades Rev.* 111, 351-5 (1925). J. F. BYRNE

Pulverized coal as fuel for copper-refining furnaces. E. S. BARDWELL AND ROY H. MILLER. *Trans. Am. Inst. Mining Met. Eng.*, Sept., 1925, No. 1497-D, 8 pp.—The use of pulverized coal in connection with melting and refining of cathode Cu has proved successful and, in case of any great increase in oil price, very profitable. Bituminous coal running less than 8% ash and 2% S is crushed, dried and pulverized. The total loss of coal in a pulverizing plant described in the paper was found to be 0.6%. Screen tests showed 96% through 100 mesh and 80% through 200 mesh. The transportation of the coal dust to the furnace refinery is undertaken in special designed tank cars. These are discharged to the bins over the furnaces by means of high pressure air. No changes were made in the furnace design when changing from grate-firing to coal dust, except for the removal of the fireboxes which proved to be unnecessary, as the burner pipes could be introduced directly over the bridge-wall. In regard to the economies a saving of time was brought about in the elimination of grating and removing of clinkers from the firebox. The conditions of combustion were more uniform; thus a shorter melting period was required. There was at least 40% saving in actual fuel cost. Compared with similar fuel for grate-firing the fuel ratio was 6.8 tons against 4 tons of Cu per ton of coal. The slag produced per ton of Cu increased 28% but contained only 3.4% more Cu than that with grate-firing. This loss also depends largely on the fineness of the coal dust used; thus a finer dust gives less slag. The quality of the Cu was excellent, and the S content seldom exceeded 0.002%. The cost of furnace-repair during a 16 months' period with coal dust firing showed a decrease of 10%. D. MIESSEY

Melting aluminium. RICHARZ. *Chem.-Ztg.* 49, 813-4 (1925).—A general presentation of the principles and practice of Al-melting. The tendency to oxidize is overcome partly through the formation of a skin of Al₂O₃ on the metal; the taking up of N and hydrocarbons increases above 720°; the high sp. ht. (0.232 cal. at 100°) renders melting slower than with Cu, etc., and cooling correspondingly longer; and as Al dissolves Zn, Cu, Ni, Si, etc., readily at high temps. the materials of which crucibles and furnaces are built are important. The advantages of oil- and gas-fired furnaces, and especially of elec. furnaces, are emphasized. W. C. EBAUGH

The technic of examining metals under the microscope. G. PIRK. *Gen. Elec. Rev.* 28, 800 (1925).—A review. C. G. F.

Endurance properties of non-ferrous metals. D. J. MCADAM, JR. *Trans. Am. Inst. Mining Met. Eng.* 1925, No. 1506-E, 22 pp.; cf. C. A. 19, 1397, 1845, 2627.—McA. has carried out expts. on the endurance properties of various non-ferrous metals and alloys (Cu, Monel metal, bronze, Muntz metal, Al-bronze and duralumin). Stress-

the former is found as a mineral of secondary development, especially in schistose rocks. The distinction between muscovite and leverrierite is not possible by ordinary petrographic or optical methods, nor by microchem. tests in samples which contain an appreciable amt. of K. The specimen giving the most conclusive evidence of the presence of leverrierite by optical and microchem. examn. gave also the best result upon X-ray analysis, and furnishes evidence of the development of this mineral under conditions of anamorphism producing schistose rocks. L. W. RIGGS

Hedyphane from Franklin Furnace, New Jersey. Wm. F. FOSHAG and R. B. GAGE. *Am. Mineral.* 10, 351-3(1925).—The analysis: Cl 2.98, As_2O_3 29.94, PbO 52.77, (Mn,Fe)O 0.28, CaO 14.98, MgO 0.10, ZnO 0.23, H_2O 0.08%, establishes hedyphane as a new species. Its $\omega = 2.026$, $\epsilon = 2.010$. C. B. SLAWSON

New investigations upon dewindtite: birefringence, chemical composition, and dehydration; comparison with dumontite. ALFRED SCHOEP. *Bull. soc. franç. mineral.* 48, 77-85(1925).—The crystals are biaxial +, 2F large, and extinction perpendicular H_2O 7.93, P_2O_5 10.14, UO_3 54.80, PbO 24.85%. C. B. SLAWSON

A new mineral from Långban. G. AMINOFF. *Z. Krist.* 60, 262-74(1924).—The compn. is: Sb_2O_3 54.17, P_2O_5 0.23, Al_2O_3 34.72, CaO 6.94, MgO 0.52, Na_2O 8.50, K_2O 0.21, H_2O 0.39 = 99.68%, corresponding to the formula $Na_2O.2Al_2O_3.Sb_2O_3$. Crystals are hexagonal, with $c = 1.6309$. Uniaxial, negative, ω 1.7724, ϵ 1.7700. This mineral is named *swedenborgite*, in honor of Emanuel Swedenborg. L. S. RAMSDELL

The genesis of the Texada Island magnetite deposits. C. O. SWANSON. Can. Bur. Mines, *Summary Rept.* 1924A, 106-44.—The probable conditions under which Fe_3O_4 was deposited from magmatic solns. are described. L. W. RIGGS

The copper deposits of Capillitas, Patamarea, Argentina. E. KITTL. *Z. prakt. Geol.* 8, 121-4; 9, 140-6(1925).—The ore deposit is associated with andesite. Primary minerals present are: pyrite, arsenopyrite, chalcopyrite, quartz, kaolin, galena, sphalerite, barite, and tetrahedrite. Minerals formed in the cementation zone are: chalcopyrite, enargite, tetrahedrite, chalcocite, bornite, covellite, pyrite. In the oxidation zone: cerussite, rhodochrosite, native Cu, cuprite, malachite, Au, braunite, limonite, linarite, and $CuSO_4$. W. H. NEWHOUSE

Upper Beaver river area, Mayo district, Yukon. W. E. COCKFIELD. Can. Bur. Mines, *Summary Rept.* 1924A, 1-18.—Deposits of galena with smaller quantities of tetrahedrite and Zn blende are found at McKay hill, Silver hill and Grey Copper hill. These ores generally carry small quantities of Ag. The outlook for profitable mining is unfavorable. L. W. RIGGS

Driftwood Creek map-area, Babine Mts., British Columbia. GEORGE HANSON. Can. Dept. Mines, *Summary Rept.* 1924A, 19-37.—Twelve mining properties are described which show Ag, Pb and small quantities of Au. The deposits are small and discontinuous. Prince Rupert to Burns Lake, B. C. *Ibid* 38-43.—The common minerals contg. Cu, Pb, Zn, Ag, Fe and As are found, also Au ores, but none of them in quantities sufficient to encourage com. development. L. W. RIGGS

Tungsten deposits near Hazelton, B. C. M. E. HURST. Can. Dept. Mines, *Summary Rept.* 1924A, 44-6.—W has been found in 2 claims. L. W. RIGGS

Chilko Lake and vicinity, B. C. V. DOLMAGE. Can. Bur. Mines, *Summary Rept.* 1924A, 59-75.—Au, Ag, Sb and As are found in the Morris mine and in other claims. The ores are low grade. L. W. RIGGS

Pemberton area, Lillooet district, B. C. C. E. CAIRNES. Can. Dept. Mines, *Summary Rept.* 1924A, 76-99.—About 12 mining properties are described, most of which show low Au, Ag and Cu values. Zn and Pb ores are less common. **Nickeliferous mineral deposit, Emory Creek, Yale mining division, B. C.** *Ibid* 100-5.—The genesis of the Ni deposits and particularly of *pentlandite* is described at length. L. W. RIGGS

Genesis of lithium pegmatites. W. T. SCHALLER. *Am. J. Sci.* 10, 269-79(1925).—The Li pegmatites as now seen are not the result of an original crystn. of a magma unusually rich in the so-called mineralizers, but the results of later replacement (probably hydrothermal) of an earlier formed rock essentially free from any of the mineralizers. The earlier formed rock in the California field was graphic granite whose peculiar structure and texture served as a key in the interpretation of subsequent rock replacements. L. W. RIGGS

A pigeonite-andesite with diabasic texture from Taodeni, Soudan, Sahara, and the origin of bowlingite from the same locality. M. E. DENAEYER. *Bull. soc. franç. mineral.* 47, 355-7(1924).—Bowlingite is an alteration product of pigeonite which has an extremely low Ca content. C. B. SLAWSON

Lower muds (older loess) of the vicinity of Paris. AGAFONOV and MILE. MAITCHEF. *Compt. rend.* 181, 300-2(1925) cf. C. A. 18, 1027.—These muds are much less

changed, less calcareous, more heterogeneous and coarser than the recently deposited muds of the locality. The probable genesis is described. I. W. RIGGS

A new attempt to determine the relative dissemination of the rare elements. G. BERG. *Z. prakt. Geol.* 5, 73-9 (1925).—Discussion of the abundance of each of the elements is followed by a table with the elements listed. W. H. NEWHOUSE

Measurement of the altitude of the ozone layer in the atmosphere. J. CARANNES AND J. DUFAY. *Compt. rend.* 181, 302-4 (1925).—Mathematical calchs. applied to data furnished by photospectroscopic observation upon the absorption of the sun's rays gave about 50 km. as the height of the ozone layer. I. W. RIGGS

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST AND R. S. WILLIAMS

The Hornsey low-temperature process for reducing iron ore. G. HOOGHWINCKEL. *Iron Coal Trades Rev.* 111, 326 (1925).—The Hornsey app. consists of 3 rotary furnaces arranged in series. Ore is fed into the upper one, where it is heated to 800° by the surplus gas from the second retort. The ore drops by gravity into the second retort where it is mixed with low-grade coal or other reducing agent. This retort is heated by an auxiliary heating system. In the third retort, the charge is cooled by H₂O sprays to a temp. where reoxidation will not occur. From here it is discharged through an air-tight opening. The retorts are operated at different speeds and at temps. never above 1050°. Fe in the final product is separated magnetically from the gang and is 98-99.5% pure. Ores ranging between 63.4 and 21.0% Fe were used. Steel made from the granular Fe without further additions is of a superior quality. J. F. B.

Notes on blast furnace slags. R. R. F. WALTON. *Iron Coal Trades Rev.* 111, 319 (1925).—The roles of SiO₂, Al₂O₃, CaO, MgS and CaS are discussed. J. F. BYRNE

Dimensions and output of German open-hearth furnaces. HUGO BONSEN. *Iron Coal Trades Rev.* 111, 351-5 (1925). J. F. BYRNE

Pulverized coal as fuel for copper-refining furnaces. J. S. BARDWELL AND ROY H. MILLER. *Trans. Am. Inst. Mining Met. Eng.*, Sept., 1925, No. 1497-D, 8 pp. The use of pulverized coal in connection with melting and refining of cathode Cu has proved successful and, in case of any great increase in oil price, very profitable. Bituminous coal running less than 8% ash and 2% S is crushed, dried and pulverized. The total loss of coal in a pulverizing plant described in the paper was found to be 0.6%. Screen tests showed 96% through 100 mesh and 80% through 200 mesh. The transportation of the coal dust to the furnace refinery is undertaken in special designed tank cars. These are discharged to the bins over the furnaces by means of high pressure air. No changes were made in the furnace design when changing from grate-firing to coal dust, except for the removal of the fireboxes which proved to be unnecessary, as the burner pipes could be introduced directly over the bridge-wall. In regard to the economies a saving of time was brought about in the elimination of grating and removing of clinker from the firebox. The conditions of combustion were more uniform; thus a shorter melting period was required. There was at least 40% saving in actual fuel cost. Compared with similar fuel for grate-firing the fuel ratio was 6.8 tons against 4 tons of Cu per ton of coal. The slag produced per ton of Cu increased 28% but contained only 3.4% more Cu than that with grate-firing. This loss also depends largely on the fineness of the coal dust used; thus a finer dust gives less slag. The quality of the Cu was excellent, and the S content seldom exceeded 0.002%. The cost of furnace-repair during a 16 months' period with coal dust firing showed a decrease of 10%. D. MIESEY

Melting aluminium. RICHARZ. *Chem.-Ztg.* 49, 813-4 (1925).—A general presentation of the principles and practice of Al-melting. The tendency to oxidize is overcome partly through the formation of a skin of Al₂O₃ on the metal; the taking up of N and hydrocarbons increases above 720°; the high sp. ht. (0.232 cal. at 100°) renders melting slower than with Cu, etc., and cooling correspondingly longer; and as Al dissolves Zn, Cu, Ni, Si, etc., readily at high temps. the materials of which crucibles and furnaces are built are important. The advantages of oil- and gas-fired furnaces, and especially of elcc. furnaces, are emphasized. W. C. EBAUGH

The technic of examining metals under the microscope. G. PIRK. *Gen. Elec. Rev.* 28, 800 (1925).—A review. C. G. F.

Endurance properties of non-ferrous metals. D. J. MCADAM, JR. *Trans. Am. Inst. Mining Met. Eng.* 1925, No. 1506-E, 22 pp.; cf. C. A. 19, 1397, 1845, 2627. —McA. has carried out expts. on the endurance properties of various non-ferrous metals and alloys (Cu, Monel metal, bronze, Muntz metal, Al-bronze and duralumin). Stress-

cycle graphs are presented and compared with the data obtained elsewhere (Univ. of Ill., McCook field) on the same materials. McA.'s graphs indicate that non-ferrous metals have an endurance limit, just as ferrous alloys, while the results of the other 2 labs. give evidence that no endurance limit was reached, neither for Monel metal nor for duralumin. Possible reasons for the discrepancy in results and conclusions are discussed.

• **Cooling causes brittleness.** S. A. RICHARDSON. *Iron Trade Rev.* **77**, 550 2(1925).

J. F. BYRNE

• **Flow in a low-carbon steel at various temperatures.** H. J. FRENCH AND W. A. TUCKER. *Bur. of Standards, Tech. Paper* **296**, 619 40(1925).—Using a low C steel (0.24% C, 0.37% Mn), F. and T. made a study of the flow under fixed loads at const. temp. within the range 20–600°, seeking to find a possible relationship between long- and short-time tensile tests. The steel was tested at 20°, 295°, 430° and 595° and the loads applied varied from 11,000 to 60,000 lb./sq. in. The relation between decrease in applied load and increase in life is approximately hyperbolic. A fixed load at const. temp. causes 3 stages of flow. (1) an initial flow, (2) a secondary flow at rather uniform slow rate and (3) a final rapid flow just previous to rupture. The secondary flow is most important when it comes to finding the possible life of a steel. No flow in the second stage means a very long life. A comparison between the loads producing "no flow" in the second period and the proportional limit in short time tests, at 295°, 430° and 595°, showed that this max. allowable load is well above the proportional limit at 295° and practically equal to it at 430° and 595°. At room temp. little difference exists between loads permitting long life and those producing fracture in a few seconds. A rise in temp. causes a more gradual increase in life with decrease in applied load. The effect of rise in temp. is mainly a reduction in the strain hardening ability of the steel. The latter is max. around 20° and becomes zero at temps. ranging between 400° and 425°.

H. S. VAN KLOOSTER

• **Steel castings and X-rays.** ANCEL ST JOHN. *Iron Age* **116**, 802 1(1925); cf. *C. A.* **18**, 517.—The preliminary work in the detn. of the size of detectable cavities in steel with X-rays is described. Investigations made with "synthetic specimens" under conditions met in actual practice showed that isolated defects having a diam. of $\frac{1}{16}$ the thickness of the part examd. could be easily detected. The X-ray equipment and arrangement of specimens are described in detail together with X-ray photographs.

D. MIESEY

• **Amorphous cement and the formation of ferrite in the light of X-ray evidence.** F. B. FOLEY. *Trans. Am. Inst. Mining Met. Eng.* **1925**, No. 1505-C, 8 pp.—A theoretical discussion based on the results of recent X-ray studies on Fe and steel leads F. to reject the amorphous cement theory. The formation of ferrite at the grain boundaries of austenite is due to a progressive breakdown of the γ -lattice whereby Fe atoms go into the make-up of cube faces (free from C) and C atoms are thrust towards the center of the crystal.

H. S. VAN KLOOSTER

• **Making seamless steel tubes by improved process.** E. F. ROSS. *Iron Trade Rev.* **77**, 1079 83(1925). The Wellman-Peters process, which uses square billets for hot piercing, is described.

J. F. BYRNE

• **Metallurgy of iron drier rolls.** J. W. BOLTON. *Iron Age* **116**, 800 2(1925).—A thoroughly systematic work in regard to mech. and chem. factors in the steel foundry has resulted in the successful casting of seamless drier rolls for paper machines. The metals used must be strong to support the heavy wt.: up to 14,000 lb. and, when molten, be fluid to run the large area, have a low contraction and resist distortion during machining. A mixt. which fulfils these demands has been worked out, and should have about the following compn.: 1.20–1.25% Si, 3.4–3.55% C, 0.4–0.8% Mn, 0.09–0.12% S and 0.35–0.60% P. In particular are the ratio Si/P and the C content of importance. The mech. technology of casting, such as the setting up of molds, removing core and machining, is outlined. Diagrams for phys. tests and analyses of material are given.

D. MIESEY

• **Mechanical properties and structure of solid solutions in systems with limited solubility in the solid state.** Investigations on solid solutions rich in Ag, of the systems Ag-Mg, Ag-Al, Ag-Sb, Ag-Sn, Ag-Zn, Ag-Cd, and Ag-Mn. J. F. SAEFFEL AND G. SACHS. *Z. Metallkunde* **17**, 155 61, 258–64, 294 8(1925).—For a number of binary Ag alloys, forming solid solns. on the Ag side of the diagram, the mech. properties and structure as functions of the concn. were investigated. In order to obtain results comparable with those of other workers it was necessary to bring the alloys, however previously treated, into a "basic" or normal condition. This was accomplished by a cold work deformation of at least 50%, followed by annealing for 30 min. at a temp.

above the recrystn. temp. (T_1) but below the temp. where coarse crystn. sets in (T_2). After the annealing the alloys were slowly cooled to obtain a stable final condition. Curves are drawn for pure Ag and various solid solns. giving the relation between hardness and annealing temp. of the cold-forged alloys. The range of temps. within which annealing can be suitably carried out is usually reduced by metals going into solid soln., since T_1 is raised and T_2 often depressed. Several "basic" mech. properties are discussed. For pure Ag the following data were obtained: When severely cold worked Ag begins to soften at 100° . After being annealed at $500\text{--}700^\circ$, it has a Brinell hardness of 25 kg./mm.^2 , a tensile strength of $12\text{--}13\text{ kg./mm.}^2$, and elongation of $15\text{--}50\%$ and a reduction in area of 90% . • A systematic study of structure and mech. properties, graphically represented by numerous curves and some photomicrographs, brought out the following new facts: In the system Ag-Mg solid solns. are formed up to about 29% Mg. A eutectic line between 7.2 to 12% Mg at 756° does not exist. In the system Ag-Al Ag can (at room temp.) contain a max. of 5.2 to 5.7% Al in solid soln., and in the system Ag-Zn at least 20.4% Zn. The graphs indicated that the mech. properties agreed well with the results of microscopic investigation. The hardening effect of the second metal is the more pronounced the greater the slope in the liquidus line and the larger the solidification range.

H. S. VAN KLOOSTER

Inner structure of alloys. WALTER ROSENHAIN. *J. Roy. Soc. Arts* **73**, 1000-21, 1022-37, 1039-52 (1925). - See C. A. **19**, 2803.

H. J. C.

Equilibrium diagrams of alloys with formation of a single compound. A. MŁODZIEJOWSKI. *Z. physik. Chem.* **117**, 361-86 (1925). - Using the methods first developed by van Rijn van Alkemade (1893) and Bakhuis Roozeboom (1899) M. has theoretically derived a number of equil. diagrams for binary alloys forming a single intermediate compd. These diagrams are obtained from a study of the curves representing the thermodynamic potential ξ as a function of the concn., both for the liquid and the solid phases, at different temps. In case the compd. forms solid solns. with the 2 components, either in all proportions or to a limited extent the ξ - c curve for the solid phase shows one or more minima and more complicated diagrams result, some of which have not yet been realized experimentally. Finally M. points out that it is not permissible, from a thermodynamic point of view, to consider the intermediate compd. as an independent component; in other words one should not, as is often done, consider a complicated diagram as made up of 2 simple diagrams joined together. H. S. VAN K.

The tempering colors in iron-carbon alloys and in the mixed crystals Fe-Ni; Fe-V; Fe-Al. G. TAMMANN AND G. STEBEL. *Z. anorg. allgem. Chem.* **148**, 297-312 (1925); cf. C. A. **17**, 3823. - Curves are given to show the relation between time of tempering, temperature, and thickness of the oxide layer (expressed in terms of the thickness of a layer of air which would give the same interference color) for cementite, pearlite, pearlitic cementite, and troostite. The velocity of the increase of thickness of the oxide layer depends entirely upon the velocity of diffusion of oxygen to the metal surface. The velocity of oxidation of the metal is so large that all O which comes in contact with the metal immediately unites with it. In cementite, the CO and CO₂ which are formed would interfere with the access of O, and the velocity of increase of thickness of the oxide layer would be decreased. In the case of Fe-Ni alloys, the oxide layer is a solid soln. of Fe and Ni oxides. The thickness of this layer varies with the Ni content for any definite time and temp., changing discontinuously at points corresponding to changes in the crystal lattice in the Fe-Ni system. The film thickness changes linearly with the Ni content within any region characterized by a single stable crystal lattice. In the case of Fe-V alloys, there is a discontinuous change in the relation between layer thickness and V content at the point where the α -iron mixed crystal changes to the γ -iron mixed crystal. For Fe-Al alloys, the velocity of oxide formation decreases with increasing Al content, probably because the oxide layer is relatively impervious to O. R. J. H.

The history of the light alloys of aluminium and the present position of their manufacture. LEON GUILLET. *Le genie civil* **84**, 298-303, 319-21, 356-9 (1925). - An account of the development of the alloys of Al with Cu, Mg, Si, Mn, Ni, Zn, etc., and the heat treatment of these alloys to secure more desirable phys. properties. J. J. H., Jr.

Concentrating ores by flotation. C. P. LEWIS. U. S. 1,560,170, Nov. 3. A suitable acid pulp of Cu-bearing slimes or other ore is agitated with a frothing agent such as pine oil and with K xanthate or a similar S deriv. of carbonic acid which serves to render the sepu. more efficient. Cf. C. A. **19**, 3472.

Smelting ores. G. W. PRINCE and A. DOUGLAS. U. S. 1,559,508, Oct. 27. In smelting ores in a reverberatory furnace, the ore is fed into the furnace chamber substantially continuously so that a continuous longitudinal mound is formed and main-

tained with its apex spaced from the side walls of the furnace chamber. U. S. 1,559,509 specifies forming a plurality of ore mounds similarly in a furnace chamber.

Smelting ores. J. A. CHURCH, JR. U. S. 1,559,510, Oct. 27. Ore is fed into a furnace chamber so as to form "gradually widening valleys" for the free flow of the molten material from the firing end toward the flue end of the furnace. U. S. 1,559,511 relates to a furnace for smelting in the same manner.

Ore flotation. F. CREMER. U. S. 1,550,512, Aug. 18. A colloid made up of freshly pptd. sulfide of the metal to be sepd. is added to ore pulps, *e. g.*, a pulp contg. Cu ore, and the pulp is subjected to froth flotation through the exclusive use of this sulfide.

Reducing ores. W. E. TRENT. U. S. 1,557,107, Oct. 13. Fe ore or other ore in finely comminuted form is mixed with carbonaceous fuel particles (such as those of coal heated sufficiently that they are substantially freed of hydrocarbon) and the fuel particles associated with the ore are then burned in a reducing atm. to reduce the ore.

Reducing ores. G. F. GREENWOOD. U. S. 1,558,262, Oct. 20. Fe oxide or other ore and a reducing agent such as C are separately preheated to a temp. above their combining temp. range, then mixed and maintained at a sufficiently high temp. for reduction.

Chloridizing ores. O. B. HOFSTRAND. U. S. 1,556,822, Oct. 13. Ores are subjected to 2 or more roasting stages, in which the materials are mixed with salt, S and coal and then roasted in the presence of air. The S is so proportioned to the other materials that sintering of the mixt. does not take place.

Impact amalgamator for treating gold ore pulps. W. W. GIBSON. U. S. 1,561,152, Nov. 10.

Apparatus for treating gold ore, etc., with cyanide solutions. G. E. C. ROUSSEAU. U. S. 1,559,914, Nov. 3.

Inclined horizontal rotary kilns or furnaces for reducing or roasting ores, etc. G. H. CLAVENGER. U. S. 1,558,965, Oct. 27.

Apparatus for concentrating and amalgamating placer deposits of gold, platinum, etc. J. H. RAE. U. S. 1,557,877, Oct. 20.

Recovering metal values from slag. H. H. STOUT. U. S. 1,559,803, Nov. 3. The entire body of a charge of molten slag, *e. g.*, that derived from the smelting of Cu ore, is brought into contact with non-molten material such as Fe or steel in bar form which reacts with ingredients of the molten slag to ppt. metallic values, *e. g.*, Cu, this non-molten material leaving a residuum which is also persistently non-molten throughout the pptg. reaction. The slag temp. is not increased during this reaction and the non-molten material is used in excess and subsequently sepd. from the slag.

Copper from ores. J. B. DUFAUR. U. S. 1,550,521, Aug. 18. Oxidized or roasted Cu ore is treated with a leaching soln. contg. Fe sulfate and the soln. is treated with SO₂ and air.

Copper from mat. A. H. HENDERSON. U. S. 1,560,574, Nov. 10. In order to facilitate the extn. of Cu from mat., the latter is treated with an alkali carbonate, fluxing agents such as alum and borax and an alkali hypochlorite, at a temp. of about incipient redness.

Treating tin ores, etc. A. A. LOCKWOOD. U. S. 1,556,449, Oct. 6. Ore or other Sn-bearing material is roasted under conditions which render constituents such as Fe oxide magnetic, subjected to magnetic sepn., and the magnetic values are crushed and mixed with non-magnetic material such as sand, the particles of which are larger than those of the Sn content. The material is subjected to a second magnetic sepn. and the residues are treated to sep. the admixed particles from the Sn content.

Tungsten. C. J. SMITHELLS. U. S. 1,559,799, Nov. 3. Before reduction of W compds. such as WO₃ to metallic form, there is added to them not more than 1% of a substance such as thoria which will introduce into the metal a non-volatile oxide irreducible by H and not more than 0.5% of an alkali metal compd. such as NaCl which is later decomposed by H.

Purifying metallurgical gases. H. A. BRASSERT. U. S. 1,560,202, Nov. 3. Metallurgical gases such as those produced in blast furnaces are passed through coke, brick checkerwork or other materials which are heated to a temp. higher than the fusion point of the impurities, so that the latter are sintered. After this treatment, the gas may be used for metallurgical or other purposes.

Vertical furnace for roasting cinnabar, zinc ore, etc. J. NORRISH. U. S. 1,551,424, Aug. 25.

Device for charging and discharging brass-smelting furnaces, etc. M. TAMA. U. S. 1,550,401, Aug. 18.

Furnace for heat-treating iron internal-combustion cylinders with copper fins, etc. C. L. LEE and T. C. VAN DEGRIFT. U. S. 1,557,208, Oct. 13.

Heat-treated zirconium steel. F. M. BECKETT and A. L. FIELD. U. S. 1,550,489, Aug. 18. A heat-treated C steel contg. Zr has higher ductility than steels of comparable strength and hardness which contain no Zr. U. S. 1,550,490 specifies an alloy steel hardened by heat treatment, contg. Zr and Cr, W, V, Mo or Mn.

Increasing the strength of steel or other metals. H. KÄNDLER. U. S. 1,557,367, Oct. 13. The surface of metal bodies is subjected successfully to the action of different corroding agents to remove discontinuities in the body surface beyond the reach of mech. tools.

Quenching and hardening steel sleeves. J. G. WEISS. U. S. 1,561,384, Nov. 10. Mech. features of hardening sleeves for roller-bearing raceways or similar articles.

Composition for cleaning and preserving iron surfaces. B. K. BROWN and E. G. SCHMIDT. U. S. 1,561,053, Nov. 10. A mixt. of mesityl oxide, acetone, 85% H_3PO_4 and H_2O , equal quantities.

Alloy steel resistant to oxidation at high temperatures. G. R. RICH. U. S. 1,560,099, Nov. 3. An alloy steel adapted for making poppet valves of internal-combustion engines contains Cr 7-8, Ni 1.25-2.25, P and S together less than 0.03, Mn 0.45-0.65, Si 0.50-1.0 and C 0.35-0.45%, the remainder being principally Fe.

Steel alloy. M. PETERS. U. S. 1,558,918, Oct. 27. A steel alloy for rollers of 14-roller rolling mills comprises Cr 2, W 1.5 and Ni 1.5%.

Aluminium steel alloy. A. W. MERRICK. U. S. 1,551,418, Aug. 25. Steel in separately melted and previously cast portions of Al steel alloy are introduced into the steel through the slag which protects the metal from the air.

Alloy of zinc, aluminium and tin. F. W. KARITZKY. U. S. 1,559,620, Nov. 3. An alloy of Zn 85, Al 10 and Sn 5% is suitable for making castings and does not shrink in the mold.

Alloy of iron, aluminium and chromium. H. S. COOPER. U. S. 1,550,508, Aug. 18. An alloy which is resistant to high temps. comprises Fe together with Al 10-16 and Cr 5% or more (but less than the % of Al). U. S. 1,550,509 specifies an otherwise similar alloy contg. Cr up to 20% (and in larger proportion than the Al). This greater Cr content serves to produce a metal workable at 600-1200° by forging, rolling or swaging.

Alloy of iron with nickel or cobalt. R. F. FLINTERMANN. U. S. 1,556,776, Oct. 13. Alloys resistant to oxidation at high temps. contain Ni or Co 20-60 and Si 3-9%, the remainder being principally Fe.

Alloys of silicon with iron or other heavy metals. R. WALTER. U. S. 1,560,885, Nov. 10. Alloy components such as ferro-Si and Fe, Mn, Ni or Co are mixed in proportions for the formation of a single homogeneous silicide, the mixt. is heated to a temp. (which may be about 1200-1300° with Fe and ferro-Si) at which exothermic reaction is initiated and the exothermic reaction then serves to melt down the charge.

Iron alloy resistant to corrosion. G. H. CHARLS. U. S. 1,560,207, Nov. 3. An alloy comprises Fe together with Si 0.5-6.0, Cr 3-30 and Mo not exceeding about 0.35%. Cf. C. A. 19, 1849.

Alloy of nickel, copper and aluminium. S. W. PARR. U. S. 1,556,953, Oct. 13. An alloy which is readily worked and resistant to corrosion comprises Ni over 50, Cu over 22, Al 2-8, Mn 0.1-1.0 and Ta 0.1% or more. The Ni should amount to 1.85-2.20 times the Cu.

Nickel-copper alloys. W. F. GRAHAM. U. S. 1,557,044, Oct. 13. Alloys which have high strength and resistance to corrosion comprise Ni 30-35 and Fe 3-7%, the remainder being Cu, free from Pb and Zn.

Nickel-chromium-copper alloy. W. F. COCHRANE. U. S. 1,557,025, Oct. 13. Alloys adapted for making engine valves, etc., comprise Cr 1-5 and Ni 20-40%, the balance being mainly Cu.

Treating copper alloys for hardening, etc. F. HEUSLER. U. S. 1,559,963, Nov. 3. Alloys contg. Cu with smaller proportions of Mn and Al, e. g., an alloy comprising Mn 10-15 and Al 7-10%, after casting, rolling or forging are subjected to a prolonged heat treatment (the duration of which may be about 20-24 hrs.) to increase their hardness and elastic limit. Zn, Sn, Fe and Si may also be present in the alloys.

Low-carbon chromium-iron alloys. P. A. E. ARMSTRONG. U. S. 1,557,132, Oct. 13. In making low-C or substantially C-free alloys of Cr and Fe, Cr, preheated to somewhat below its m. p., is introduced into molten Fe.

Zinc-copper-aluminium alloy. E. MAASS. U. S. 1,550,730, Aug. 25. An alloy which is suitable for bearings, bushings, bands on projectiles, etc. comprises Zn 100, Cu 3 and Al 5 parts.

Aluminium-gold-copper alloy. M. E. PAGE. U. S. 1,560,845, Nov. 10. An alloy which is suitable for denture bases comprises Al 93.20, Au 4.55 and Cu 2.25%.

Gold copper alloy. V. D. DAVIGNON. U. S. 1,557,431, Oct. 13. A homogeneous ductile and malleable alloy comprises Au 58, Cu 37 and Al 5%.

Silver and gold alloy for electric contacts. E. F. KINGSBURY. U. S. 1,561,247, Nov. 10. An alloy adapted for making elec. contacts comprises Au 72 and Ag 26.2%, the balance being base metal such as Ni 1.8%.

Magnesium alloys. W. R. VEAZEY and E. C. BURDICK. U. S. 1,558,066, Oct. 20. In making alloys consisting largely of Mg, other metals such as Al, Sn, Zn, Cu or Cd are first fused with a relatively small quantity of Mg and the resulting alloy is then added to the remaining quantity of Mg in molten state. $MgCl_2$ and NaCl may be used as a flux.

Brass alloy for bearings. J. VADERS. U. S. 1,551,443, Aug. 25. A brass alloy is formed contg. Si 0.6-1.5% and sufficient Mn (usually about 2-2.5%) to counteract the detrimental effects of the Si. Fe and Al in small aunts. also may be added.

Non-rusting alloy. M. S. CLAWSON. U. S. 1,557,981, Oct. 20. An alloy which is suitable for table ware, builder's hardware, etc., comprises Ni 82-96, Si 3-10, Mn 1-5, Cr 1-5, C 0.85-3.5, Fe 1-6, and Cu 0.5-4.0%, together with a small proportion of reducing, deoxidizing, and denitrogenizing elements such as Ti and Al, U or Ce.

Soldering aluminium. S. SPOGANITZ. U. S. 1,550,987, Aug. 25. Hot solder is applied in the presence of a flux formed of beef tallow, mutton tallow, beeswax, heavy machine oil and rosin.

Welding different steels together. J. B. DAILEY. U. S. 1,550,951, Aug. 25. The joint to be welded between high speed steel and low C steel is coated with a mixt. composed of equal parts by wt. of Cu powder and borax, the joint is heated until the mixt. melts and the steels are joined together. The joint is then quenched and the high speed steel simultaneously hardened by immersing the weld and the high speed steel in oil or other tempering fluid.

Gas for use in welding and cutting metals. R. H. BROWNLEE and R. H. UHLINGER. U. S. 1,551,235, Aug. 25. A gas adapted for use with O in cutting or welding metals comprises about 75% or more H and 5% or more hydrocarbons.

Melting and refining bronze, copper, nickel, tin or other non-ferrous metals. D. CUSHING. U. S. 1,556,591, Oct. 13. The metal is melted in direct contact with incandescent pitch coke which is substantially free from ash and materials which would have a deleterious effect on the metal.

Rust-producing composition. R. MATTICE. U. S. 1,559,341, Oct. 27. A mixt. adapted for scaling pores in metal pipes, etc., comprises magnetized Fe filings 60, NH_4Cl 40 and S 0.1-0.5 parts.

Carburizing composition. G. W. PRESSELL. U. S. 1,556,347, Oct. 6. A mixt. is used comprising coke and charcoal 80-90% and 10-20% of C impregnated with cyanide. Na_2CO_3 and $CaCO_3$ also may be present.

"Soldering compound." J. C. SHOTTON. U. S. 1,557,348, Oct. 13. A mixt. adapted for soldering Au comprises borax, glycerol and AuCl or other metal product which is adapted to be fused and decomposed by heat, leaving the metal residue at a temp. below the m. p. of the metal itself.

Galvanizing flux. U. RAJRA. U. S. 1,560,933, Nov. 10. NH_4Cl is mixed with 2-3% of a mixt. formed of $SrCO_3$ or equiv. Sr bearing material 124, S 62.5, a Bi-contg. material such as Bi nitrate 25.6 Na_2CO_3 13.6 and NaCl 5 parts.

Casting ingots. W. P. BROWN. U. S. 1,560,036, Nov. 3. Molten steel is cast into a vertical ingot and its entire exterior portion is chilled to form a solidified shell around the mass. The chilling is regulated to progress downwardly at a higher rate than the inward chilling, which serves to prevent undesirable segregation.

Flux. J. A. SMITH. U. S. 1,556,968, Oct. 13. A flux for welding cast Fe, etc., comprises borax 64, powdered "carbon" 14, graphite 16, Si 4, Ca phosphate 8 and superphosphate 16 parts.

Purifying molten metals. R. MATTICE. U. S. 1,559,342, Oct. 27. In purifying molten metal such as Fe or steel, a container which holds lime, borax and Al (the latter being coarser than 150 mesh) is immersed in the molten metal.

Smelting. J. O. AMBLER, H. H. STOUT and S. BISHOP. U. S. 1,550,655, Aug. 25. A Cu ore or other ore to be smelted is fed into a smelting furnace to form a pile having a portion in contact with one of the outer walls of the furnace and additional ore is fed through this portion of the wall into the interior of the pile to prevent disturbance of the surface of the pile which is exposed to the smelting flame.

Brazing. C. L. PAULUS. U. S. 1,550,629, Aug. 18. In partially brazing together

articles of Fe or steel, portions of the material are coated with a "rejecting coating" comprising Na silicate and graphite and the material is then subjected to dip brazing.

Working metals. J. G. DE LATTRE and H. HARDY. U. S. 1,559,077, Oct. 27. Fe or steel or other metals which are to be drawn, rolled or otherwise mech. worked are preliminarily provided with a metallic lubricating coating of Cu and Hg which are deposited electrolytically to form an amalgam.

Shrink head casings for ingot molds. F. H. CHAPIN. U. S. 1,558,237, Oct. 20. Furnace slag is mixed with about one-seventh as much of a binder such as portland cement, molded and baked at a temp. of 93–121° to remove moisture and render the casing porous.

Coating metal molds. D. H. MELOCHE. U. S. 1,560,838, Nov. 10. A wash for forming a protective coating on molds such as those formed of cast Fe and used for casting Fe comprises a small quantity of "C" grade Na silicate in soln. and a relatively large quantity of fire clay or other refractory powder in suspension.

Mold for casting metals. A. T. GRAHAM. U. S. 1,550,957, Aug. 25. In making molds for dental or other metal castings, granular particles such as sand and metal particles are used in sufficient amt. to give the mold approx. the same coeff. of expansion and contraction as the metal to be cast.

Apparatus for coating molds with lampblack. G. A. EYNON, D. H. MELOCHE and S. M. UDALL. U. S. 1,550,685, Aug. 25.

Thermostatically controlled device for supplying gases to molds for casting metals. S. M. UDALL. U. S. 1,550,719, Aug. 25.

Malleable castings. W. H. SMITH. U. S. 1,556,642, Oct. 13. Sn in fluid state is maintained in contact with the walls of molds such as those formed of metal and in which malleable Fe castings are cast, in order to produce good castings by regulated cooling without need of subsequent heat treatment.

Metal tools and dies. K. SCHRÖTER and W. JENSEN. U. S. 1,551,333, Aug. 25. Tools or dies adapted for drawing wires, etc., are formed of metals of the 4th, 5th and 6th periodic groups fusible above 1000°, e. g., of Ti, Zr, Th, Si, V, Ta, Cr, Mo, W or U, with surface portions of such metal in combination with a metalloid, e. g., C or B.

Bearings of copper, tin and graphite. H. M. WILLIAMS. U. S. 1,556,658, Oct. 13. Compressed bearings are formed of a mixt. of finely divided Cu 100, Sn 10 and graphite 6 parts, the formed material is packed in lampblack in a sealed container and heated to 590–760° for 5–7 hrs., cooled, ground or broached and treated with oil.

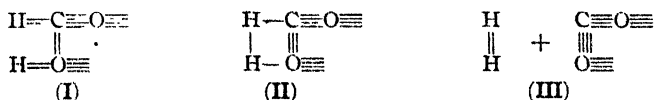

10—ORGANIC CHEMISTRY

CHAS. A. ROUHLER and CLARENCE J. WEST

Recent advances in science: organic chemistry. O. L. BRADY. *Science Progress* 20, 205–11 (1925).—Review of recent work on tautomerism. JOSEPH S. HEBURN

Repulsive action of mutually equal and mutually differing groups in saturated organic compounds. J. BÖESEKEN. *Proc. Acad. Sci. Amsterdam* 28, 371–85 (1925). See C. A. 19, 2193. E. J. C.

The problem of the mechanism of organic reactions. ERICH MÜLLER. *Z. Elektrochem.* 31, 46–50 (1925); cf. following abstr. — A discussion of the decompn. of HCO_2H (I) into CO_2 and H from the point of view of electron affinity. It is suggested that I is in a state of equil. between a large amt. of an inactive form and a small amt. of an active form (specified) which can readily change to CO_2 and H when a suitable catalyst is introduced. I is considered then, metastable, since the catalyst, which cannot add energy, yet causes decompn. It is assumed that in the active or intermediate form, a partial rearrangement of electrons has taken place tending toward the final result, but that this change sets up a chem. polarization or stress, which opposes further change, and which only a catalyst (or depolarizer) can relieve, thus allowing the change to proceed. Thus:

where the lines represent outer-shell electrons. I represents the bulk of HCO_2H , II the active form, and III the final result. Similar forms and reasoning are applied to the catalytic decompn. of AcCO_2H to CO_2 and AcH , the chlorination of CH_4 , the

esterification of acids, and the decompn. of malonic acid to CO_2 and AcOH .

M. A. YOUTZ

The catalytic decomposition of formaldehyde. III. ERICH MÜLLER AND FRIEDRICH MÜLLER. *Z. Elektrochem.* 31, 41-5 (1925).— HCHO (I) is catalytically decompd. by Ru, Rh, Pd and Os to gaseous products (CO_2 , CO , H_2 and CH_4). To 25 cc. of 13% I, free from acid and MeOH , and boiling under a reflux, was added the metal or compd. and the gases were collected and analyzed. Ru metal (0.1 g.), by reduction of $\text{Ru}(\text{OH})_3$ with H at 125° , gave only 8 cc. of gas. $\text{Ru}(\text{OH})_3$ (0.15 g.), pptd. from RuCl_3 with NaOH , gave 441 cc. of gas with 65-66.5% CO_2 , 16.3-17.3% CO , 16.8-17.4% H_2 . Rh metal (0.1 g.), reduced from alk. bicarbonate soln. with HCO_2H , gave 35 cc. of gas with 16.5% CO_2 , 45% CO , 35.6% H_2 , 2.7% CH_4 . Rh oxide (0.17 g.) gave 100 cc. of gas with 50.2% CO , 4.6% CO_2 , 43.0% H_2 , 1.9% CH_4 . Pd metal (0.1 g.), from PdO by H at 150° , gave almost no gas. PdO (0.14 g.), from K_2PdCl_4 and Na_2CO_3 , gave at first 75% CO_2 and the balance CO and H but after an hr., 3.2% CO_2 , 57.0% CO , 39.2% H and no CH_4 . 0.3 g. of K_2PdCl_4 gave practically no gas. Os metal (0.1 g.), from the oxide at 150° with H, gave 75.0-82.5% CO_2 , 1.1-2.5% CO , 11.6-19.2% H, 3.1-4.5% CH_4 . K_2OsO_4 gave a gas with about the same compn. Ir, either as metal or Na_3IrCl_6 , gave little gas. Pt, as metal or H_2PtCl_6 or PtO_2 , gave little gas and this chiefly CO_2 . The following catalytic decompn. reactions of CH_2O are discussed, hypotheacating a complex series of equil., and intermediate substances, various ones of which are attacked by different catalysts to give the products observed: $\text{H}_2\text{CO} + \text{H}_2\text{O} = \text{HCO}_2\text{H} + \text{H}_2$; $2\text{H}_2\text{CO} + \text{H}_2\text{O} = \text{HCO}_2\text{H} + \text{MeOH}$; $\text{H}_2\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + 2\text{H}_2$; $\text{H}_2\text{CO} = \text{CO} + \text{H}_2$; $2\text{H}_2\text{CO} = \text{CO}_2 + \text{CH}_4$; $3\text{H}_2\text{CO} + \text{H}_2\text{O} = \text{CH}_4 + 2\text{HCO}_2\text{H}$; $3\text{H}_2\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + 2\text{MeOH}$.

M. A. YOUTZ

A physico-chemical study of some organic syntheses. CAMILLE MATHIEON. *Bull. soc. chim.* 37, 825-36 (1925).—It is readily possible to decide from the heats of reaction and van't Hoff's equation and the principles of equil. whether certain synthetic reactions starting with simple gaseous substances could be realized, granted a suitable catalyst, or would be entirely unattainable without the introduction of energy in some form. E. g., $\text{CO} + 2\text{H}_2 = \text{MeOH} + 27.2$ Cals. $K = (p_1 \times p_2^2)/x$, where p_1 , p_2 and x are the pressures of the substances concerned in atm. K can be calcd. for any other temp. by the relation $\log K = -27,200/457T + 3.5 \log T + 4.3$. Then for assumed, but possible, values for p_1 , p_2 , x can be calcd. If it is relatively large at the temps. and pressures used, the reaction is possible, but if x is small, the reaction could not possibly be realized. In the above case, at 227° and $p_1 = p_2 = 50$ atm., $x = 1.8 \times 10^3$. At $p_1 = p_2 = 1$, $x = 1/70$. At 327° , the equil. is less favorable but still possible, while at 427° it would be practically useless. Similar calcs. are used to show that primary aliphatic alcs., AcOH and EtCO_2H could be made from CO and H_2 but that CH_3CO could not be. From C_2H_4 and H_2 the satd. hydrocarbons could be formed, also Me_2CO and PrOH from C_2H_4 , CO and H_2 . From CH_4 and H_2O , CO and H_2 might be made at a rather high temp., but CH_4 and CO and H_2 could not give EtOH nor could CH_4 alone give C_2H_6 , etc. Since in general any catalyst which assists a reaction toward equil. also assists the opposite reaction toward equil., the search by catalysts for reactions shown by the above methods to be possible can be simplified by searching for decompn. catalysts for the final substances desired. E. g., find catalysts for the decompn. of AcOH to CO and H_2 , and the same catalysts will serve for the synthesis of AcOH from CO and H_2 .

M. A. YOUTZ

Action of bromine on hydrocarbons. Bromination of isopentane. B. K. MEREFKOWSKY. *Bull. soc. chim.* 37, 861-71 (1925).—1,2,3-Tribromoisopentane (I), made by the action of Br and Fe on $\text{Me}_3\text{CBrCHBrMe}$, $b_{17} 117^\circ$, $b_{30} 128.4^\circ$, $n 1.55801$, 1.562278 , 1.573247 , 1.58141 for α , β , δ and γ at 20° (this same order is followed below), $d_4^{20} 2.11267$, $d_4^{20} 2.08212$. The constitution was established by treatment with AcOK , giving the acetate of an unsatd. Br alc. This was hydrolyzed to the alc. and the latter oxidized with KMnO_4 and the products were examd. 2-Methyl-3-bromo- Δ^2 -3-butene-1-ol, $b_{30} 103-4^\circ$, $n 1.501123$, 1.50500 , 1.513294 , 1.51164 , $d_4^{20} 1.47238$, $d_4^{20} 1.44986$. Acetate, $b_{30} 107-9^\circ$, $n 1.48108$, 1.480948 , 1.48958 , 1.49526 , $d_4^{20} = 1.38054$, $d_4^{20} 1.35523$. I was brominated to a tetrabromide which was shown to be probably a mixt. of 10% of 1,2,3,4-tetrabromo- and the balance 1,1,2,3-tetrabromoisopentane (II), $b_{18} 155-6^\circ$, $b_{16} 160-1^\circ$, $n 1.60167$, 1.60519 , 1.615885 , 1.62768 , $d_4^{20} 2.41822$, $d_4^{20} 2.38358$. Treatment of II with AcOK and AcOH gave the acetate of an unsatd. alc., probably $\text{MeCBr:C}(\text{CH}_3\text{OH})_2$. The alc. $b_{18} 154-6^\circ$. The acetate, $b_{18} 144-6^\circ$, $d_4^{20} 1.5364$, $d_4^{20} 1.5146$, $n_{D_D}^{20} 1.50409$. I with solid KOH gave the unsatd. dibromide in 80% yield. 1,3-Dibromo-2-isopentene, $b_{40} 95.6^\circ$,

b_{751} 179.5° (slight decompn.), n 1.53725, 1.54141, 1.55260, 1.56145, d_4^{20} 1.77529, d_4^{20} 1.74611, oxidized in the air very rapidly. With Br, it gave 1,2,3,3-tetrabromoisopentane, b_{14} 146°, n 1.59557, 1.60157, 1.61222, 1.62725, d_4^{20} 2.36200, d_4^{20} 2.32906. With AcOK and AcOH it gave a product b_{13} 116–7°.

X-rays and the constitution of the hydrocarbons from paraffin wax. S. H. PIPER, DENNIS BROWN AND STANLEY DYMENT. *J. Chem. Soc.* **127**, 2194–200 (1925).—The hydrocarbons isolated by Francis from Scotch paraffin wax (*C. A.* **16**, 2301) as well as synthetic $C_{20}H_{42}$, $C_{27}H_{56}$ and $C_{34}H_{70}$ have been examd. with the X-ray; the results indicate that the hydrocarbons from the wax are identical in constitution with the synthetic normal hydrocarbons: the unknown hydrocarbon line coincides in slope with the line on which the synthetic hydrocarbons lie and the intensity of the lines falls off uniformly with increasing order. The values obtained did not accord with the mol. wt. detns. of F; re-exam. of these detns., by Menzies and Wright's method, gave values agreeing fairly well with those from the X-ray study. The hydrocarbons range from $C_{23}H_{48}$ to $C_{32}H_{66}$.

Hydrogenation of ethylene in the presence of metallic calcium. R. N. PEASE AND LELAND STEWART. *J. Am. Chem. Soc.* **47**, 2763–6 (1925).—Metallic Ca or CaH_2 will catalyze the combination of C_2H_4 and H_2 , but it is very doubtful whether the reaction of C_2H_4 with the CaH_2 is one stage in the reaction.

Polarity and activation. T. M. LOWRY. *Chemistry and Industry* **44**, 970–2 (1925).—Discussion of recent work relating to the theory of polarity in reference to substitution in aromatic compds.

Alkyl and alkylene bromides. OLIVER KAMM AND C. S. MARVEL. *Organic Syntheses I*, 1–13 (1921).—Methods of prepn. of HBr , $CH_3CH_2CH_2Br$, iso- C_4H_9Br , $BuBr$, $EtBr$, $C_7H_{15}Br$ and $(CH_2)_3Br_2$ from $ROH + HBr$ or $ROSO_3H + HBr$.

Butyl chloride. J. F. NORRIS. *Organic Syntheses V*, 27–9 (1925).— $BuOH$, added to a cold mixt. of concd. HCl and $ZnCl_2$ and the mixt. refluxed 3.5–4 hrs., gives 64–6% $BuCl$.

Methylene iodide. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 57–9 (1921).—Prepn. of CH_2I_2 from MeI , Na_2AsO_3 and $NaOH$; 90–7% yields.

Trimethylene cyanide. C. S. MARVEL AND E. M. MCCOLM. *Organic Syntheses V*, 103–4 (1925).— $CH_2(CH_2Br)_2$ and $NaCN$ in dil. $EtOH$ are refluxed for 30–40 hrs., giving 77–86% $CH_2(CH_2CN)_2$.

1,2,3-Tribromopropane. J. R. JOHNSON AND W. L. MCEWEN. *Organic Syntheses V*, 99–101 (1925).— $BrCH_2CH_2CH_2Br$ in CCl_4 is brominated at -5° to 0° , giving 96–8% of $BrCH_2CHBrCH_2Br$.

Butyl butyrate. G. ROSS ROBERTSON. *Organic Syntheses V*, 23–5 (1925).— $BuOH$, oxidized by $Na_2Cr_2O_7$ and H_2SO_4 , gives 41–7% $PrCO_2Bu$.

Methylhexylcarbinol (capryl alcohol). ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 61–6 (1921).—Prepn. of $C_{10}H_{20}O_2$ from castor oil, the yield varying from 23 to 41%.

Allyl alcohol. OLIVER KAMM AND C. S. MARVEL. *Organic Syntheses I*, 15–9 (1921).—Prepn. of $CH_2=CHCH_2OH$ from $C_3H_5(OH)_3$ and HCO_2H .

2,3-Dibromopropene. R. LESPIEAU AND M. BOURGUEL. *Organic Syntheses V*, 49–51 (1925).— $BrClCH_2CHBrCH_2Br$ (200 g.), 10 cc. H_2O and 50 g. $NaOH$ give 74–84% $BrClCH_2CBr=CH_2$.

Catalytic preparation of ether from alcohol by means of aluminium oxide. R. H. CLARK, W. E. GRAHAM AND A. G. WINTER. *J. Am. Chem. Soc.* **47**, 2748–54 (1925).—The max. % of Et_2O was obtained from the catalyst prepd. by dehydration of cryst. $Al(OH)_3$ resulting from the spontaneous decompn. of solns. of $Na_2Al_2O_4$. The highest yield (80.8%) was obtained at 250° . $EtOH$ was obtained from equimol. quantities of Et_2O and H_2O , showing the reaction to be reversible. The position of equil. has been detd. at 250° to correspond to a max. possible conversion to Et_2O of about 85%. The corresponding equil. const. is 8.0. Absolute purity of the catalyst is essential. Impurities may be quickly and completely removed by alternately heating to 350° and washing again. Heating the catalyst to about 400° (but not higher), in drying, was found to give the most active product. The catalysts retain their activity, unimpaired, after long use.

Reactions of β,β' -dichloroethyl sulfide with amino compounds. W. E. LAWSON AND E. EMMET REID. *J. Am. Chem. Soc.* **47**, 2821–36 (1925).—Since NH_2 compds. are important constituents of living tissues, the reactions of $(ClCH_2CH_2)_2S$ (I) with

$\text{CCH(OH)CH}_2\text{CO}_2\text{Me}$ is reduced by Zn and AcOH to the unstable *Me ester*, b_{36} 95–100°, of γ, γ -dichlorobutyric acid, m. 103–4°. The acid is stable, while the esters and salts are unstable; during hydrolysis of the ester, some of the CHCl_2 group is also hydrolyzed. Dichloralurea is reduced to tetrachlorodethyleurea, m. 222° (decompn.). Dichloralthiourea, m. 150–1° (decompn.), is reduced to tetrachlorodethylethiourea, m. 162–3°. Chloralurethan gives dichloroethyleurethan, b_{36} 125–8°, m. about 13° (chloralurethylan, m. 125–8°, gives dichloroethyleurethylan, m. 90–3°; satn with HCl gives the compd. $\text{C}_3\text{H}_3\text{O}_2\text{NCl}$, m. 118–20°). C. J. WEST

The exchange of functional groups between two molecules. The passage of ketones to alcohols and the reverse. A. VERLEY. *Bull. soc. chim.* 37, 871–4 (1925).—The boiling of a mixt. of 40 g. of Me nonyl ketone (I) and 200 g. EtOH, contg. 10 g. of Al as Al(OEt)_3 , did not result in any change of ketone to Me nonyl alc. (II). But the use of $\text{Al(OCHMe}_2)_3$, prepd. from NaOCHMe_2 and AlCl_3 , gave II slowly in about 20 hrs. When 200 g. of I in 500 cc. of EtOH contg. 5 g. Na as NaOEt , was boiled, the reaction was complete in 5–6 hrs. Yield 92%. The reaction is very general except for cyclic ketones such as camphor, pulegone, thujone and menthone. The reverse of this change is illustrated by the change of *sec*-octyl alc. to Me hexyl ketone by boiling with Na and BzMe. The latter was changed to PhCH(OH)Me . The following fairly general reactions seem to occur: $\text{RCOMe} + \text{MeCHR'ONa} \rightarrow \text{RCMe(O'Na)OCHR'Me}$; $\text{RCMe(O'Na)OCHR'Me} \rightarrow \text{RCHMeOCR'(O'Na)Me}$; $\text{RCHMeOCR'(O'Na)Me} \rightarrow \text{RCHMeONa} + \text{MeCOR'}$; $\text{RCHMeONa} + \text{R'CHMeOH} \rightarrow \text{RCHMeOH} + \text{R'CHMeONa}$. Hence the alcoholate is regenerated and only need be present in small amt. M. A. YOURZ

Acetone-isoacetone equilibrium. WM. L. EVANS AND WM. D. NICOLL. *J. Am. Chem. Soc.* 47, 2780–92 (1925).— Me_2CO may be enolized in aq. solns., thus giving rise to the formation of isoacetone, which is in dynamic equlib. with Me_2CO , a relationship entirely analogous to the well-known behavior of $\text{AcCH}_2\text{CO}_2\text{Et}$, $\text{CH}_2(\text{CO}_2\text{Et})_2$, etc. The effect of increasing the concn. of the alkali up to $3.69 \times 10^{-2} M$ is one that gives rise to a corresponding increase in the concn. of the isoacetone mols. The wt. of the basic Hg isoacetone obtained at this concn. of alkali is equiv. to 26.5% of the original Me_2CO used. Beyond this concn. the Me_2CO and isoacetone are in equlib. It is possible to det. quant. the relationship of isoacetone concn. to the alkali concn. at the end of 24 hrs. at 25° through the formation of basic Hg isoacetone, $(\text{Ac} \cdot \text{CH}_2)_2\text{Hg} \cdot 2\text{H}_2\text{O}$, by adding freshly pptd. HgO to aq. soln. of Me_2CO contg. various concns. of KOH. The relationship between 0.2116×10^{-2} and $3.69 \times 10^{-2} M$ KOH soln. was found to be logarithmic. C. J. WEST

Mesityl oxide. J. B. CONANT AND NEAL TUTTLE. *Organic Syntheses* 1, 53–5 (1921).—Prepn. of $\text{Me}_2\text{C}(\text{CHAc})_2$ from $\text{Me}_2\text{C(OH)CH}_2\text{Ac}$ by distg. with a trace of I. C. J. WEST

Pinacolin. G. A. HILL AND E. W. FLOSDORF. *Organic Syntheses* V, 91–2 (1925).—Pinacol hydrate and 6 N H_2SO_4 are distd., giving 65–72% $\text{Me}_2\text{C}(\text{Ac})_2$. C. J. WEST

Benzalpinacolin. G. A. HILL AND G. M. BRAMANN. *Organic Syntheses* V, 15–6 (1925).— $\text{Me}_2\text{C}(\text{Ac})_2$ and BzH, shaken with EtOH–NaOH for 32 hrs. at room temp., give 88–93% $\text{Me}_2\text{C}(\text{COCH} \cdot \text{CHPh})_2$. C. J. WEST

Ethyl orthoformate. W. E. KAUFMANN AND E. E. DREGER. *Organic Syntheses* V, 55–8 (1925).— CHCl_3 , EtOH and Na give 45% CH(OEt)_3 . C. J. WEST

Insecticidal principle of insect powder (*Chrysanthemum cinerarifolium*, Bocc.). RYO YAMAMOTO. *Sci. Papers Inst. Phys. Chem. Research* 3, 193–222 (1925). [In English.]—A collective paper, giving results covered by C. A. 13, 1221; 17, 2704; 18, 3169. C. J. WEST

dl-Methylethylacetic acid. HENRY GILMAN AND H. H. PARKER. *Organic Syntheses* V, 75–7 (1925).— MeEtCHMgBr and CO_2 give 66–7% $\text{MeEtCHCO}_2\text{H}$. C. J. WEST

Oxidation products of oleic acid. II. Degradation of dihydroxystearic acid. ARTHUR LAPWORTH AND F. N. MOTTRAM. *J. Chem. Soc.* 127, 1987–9 (1925); cf. C. A. 19, 2930.—Oxidation of 5 g. dihydroxystearic acid in 10 g. NaOH in 1000 cc. H_2O , to which 3000 cc. ice H_2O was added and then 2000 cc. 1% KMnO_4 at the ordinary temp. for 2.5 hrs. gave at least 80% $\text{HO}_2\text{C}(\text{CH}_2)_4\text{CO}_2\text{H}$; $\text{Me}(\text{CH}_2)_6\text{CO}_2\text{H}$ (70%) and $(\text{CO}_2\text{H})_2$. By Edmed's original method (*J. Chem. Soc.* 73, 628), both suberic and azelaic acid are formed. C. J. WEST

Electrolytic reduction of oximes. II. γ -Isonitrosovaleric acid and α -isonitroso-propionic acid. MASAYOSHI ISHIBASHI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8A, 37–42 (1925); cf. C. A. 18, 631 [In English].— γ -Isonitrosovaleric acid is electrolytically reduced

(0.5 amp./100 cm.²) at 3–5° in 5% H₂SO₄, giving 84% of the NH₂ acid (61% current yield). With 15% H₂SO₄ the yield drops to 53%; increasing the current d. from 0.25 to 3 amps. gives an increasing yield from 71.5 to 93.1%; at 20°, the yield drops to 5.67% (0.5 amp.); a Hg cathode gave 90.9%; Pb, 80.3%; Sn, 79.5%. α -Isonitrosopropionic acid is reduced (4–5 amp./100 cm.²) at 7–10° in 8% H₂SO₄ with a 95% yield (93% current yield). The NH₂ acid m. 276–8°; mol. wt. 0.1540 g. in 18.5930 g. H₂O (f. p.), 76.6; 0.2302 g., 78.5; 0.3137 g., 81.3; from these values the degree of ionization is calcd. to be: 0.16, 0.13, 0.10. **III. Benzil dioxime.** *Ibid* 383–9.—The electrolytic reduction of β -benzil dioxime in EtOH-H₂O H₂SO₄ (1.5 amp./100 cm.²) for 6 hrs. at 16–8° gives a *toluylene hydrate*, m. 61±2°, mol. wt. in freezing C₆H₆, 201; (PhCNH₂)₂; both *meso* and *dl* forms; tetraphenylaldine; *n*- and isodiphenyloxyethylamine, benzopinacol; desoxybenzopinacol, *n*- and isohydrobenzoin. Both the α - and β -benzil dioxime behaved similarly. C. J. WEST

A. Reaction of bromine with aliphatic acids. Catalytic effect of acyl halides. H. B. WATSON. *J. Chem. Soc.* 127, 2067–82 (1925). The action of Br upon AcOH, EtCO₂H and PrCO₂H at 100° is reported. When no catalyst is present initially, the course of the reaction indicates autocatalysis by the HBr formed: a period of acceleration is followed by the attainment of a max. velocity, and the reaction then becomes steadily slower; variation in the initial concn. of the Br has a marked effect. If HBr is present initially, the reaction proceeds more quickly; a very small amt. of the halogen acid reduces the period of acceleration to a marked extent and in the presence of a moderate initial concn. of HBr (0.2 M) this period disappears. HCl also exerts a catalytic effect but it is somewhat less effective than HBr. Cl₃CCO₂H has no perceptible effect; H₂SO₄ also has but little effect but the bromination is here complicated by side reactions. If Ac₂O is not in excess of the H₂O present in the acid, no catalytic effect is observed. When the anhydride is in excess of the H₂O, a short period of acceleration is followed by a rapid reaction; after the initial period the velocity is proportional to the concn. of the Br and varies directly and almost proportionately with the concn. of the Ac₂O. If HBr, in excess of the Ac₂O, is also introduced, the initial period of acceleration disappears and the velocity is proportional to the concn. of Br from the commencement of the reaction. The actual value of k_1 is somewhat smaller than without the HBr and becomes very considerably smaller when the concn. of HBr is very high. The presence of HCl in excess of the Ac₂O does not destroy the catalytic effect of the latter but exerts a comparatively small retarding influence. When AcBr is not in excess of the H₂O present in the acid, the reaction follows the same course as when HBr alone is introduced, while the AcBr in excess of the H₂O is an exceedingly powerful catalyst. Its effect is similar to that of Ac₂O at equiv. concn. save that the velocity is now proportional to the concn. of Br from the commencement and the values of k_1 are somewhat lower and in agreement with the values obtained in the presence of Ac₂O and HBr in conjunction. The effect of AcCl, when not in excess of the H₂O present, is similar to that of HCl, while if it is in excess of the H₂O the bromination is initially much faster than in the presence of halogen acids, but less rapid than in the presence of AcBr. Other acid bromides bring about an acceleration identical with that produced by AcBr at an equiv. concn. The introduction of BzCl into a reaction mixt. of Br and AcOH produces an effect which is similar to that of AcCl at equiv. concn., except that the velocity is slightly less. For a discussion of the mechanism and the tables and curves showing the results, the original must be consulted. C. J. WEST

Ethyl cyanoacetate. E. P. KOHLER AND C. F. H. ALLEN. *Organic Syntheses* III, 53–6 (1923).—ClCH₂CO₂Na and NaCN are made to react and the resulting NCCl₂CO₂Na is esterified with EtOH in the presence of H₂SO₄. Yield of NCCH₂CO₂Et, 65–75%. C. J. WEST

Ketene. C. DEW. HURD. *Organic Syntheses* IV, 39–42 (1925); cf. C. A. 19, 1853.—The app. and method of prepn. of CH₂:CO from Me₂CO are described. The yields are about 25–30%; the product is identified as PhNHAc. C. J. WEST

Ketenes in the Friedel and Crafts reaction. C. DEW. HURD. *J. Am. Chem. Soc.* 47, 2777–80 (1925).—CH₂:CO, in the presence of AlCl₃, reacts with C₆H₆, PhOMe and C₁₀H₈, to form rather complex mixts. from which ketones may be isolated. Scarcely any reaction occurs between CH₂:CO and PhCOMe. In the case of C₁₀H₈, 21–37% of C₁₀H₇COMe was obtained, being a mixt. of the α - and β -isomers. CH₂:CO and AlCl₃ form an addn. product which is capable of reacting with aromatic compds. with the evolution of HCl; ketones are found in the reaction mixt. C. J. WEST

Acetamide. G. H. COLEMAN AND A. M. ALVARADO. *Organic Syntheses* III, 3–5 (1923).—AcNH₂ in 87–90% yields is obtained by distg. AcONH₄. C. J. WEST

Pinacol hydrate. ROGER ADAMS AND E. W. ADAMS. *Organic Syntheses* V, 87–9

(1925).— HgCl_2 in Me_2CO is added to a mixt. of Mg turnings and C_6H_6 and the resulting Mg complex decompd. with H_2O , giving 43–50% pinacol hydrate. C. J. WEST

Ethylene cyanohydrin. E. C. KENDALL AND B. MCKENZIE. *Organic Syntheses* III, 57–9(1923).— $\text{HO}_2\text{CH}_2\text{CH}_2\text{Cl}$ and NaCN give about 80% of $\text{HOCH}_2\text{CH}_2\text{CN}$. C. J. WEST

Glycerol α -monochlorohydrin. J. B. CONANT AND O. R. QUAYLE. *Organic Syntheses* II, 33–5(1922).—Glycerol in AcOH at $105\text{--}10^\circ$ is treated with HCl for about 4 hrs., giving about 66% of $\text{ClCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$. C. J. WEST

Glycerol α,γ -dichlorohydrin. J. B. CONANT AND O. R. QUAYLE. *Organic Syntheses* II, 29–31(1922).— $\text{C}_3\text{H}_5(\text{OH})_3$ in AcOH is satd. with HCl , giving 57% of $(\text{ClCH}_2)_2\text{CHOH}$. C. J. WEST

Epichlorohydrin. H. T. CLARKE AND W. W. HARTMANN. *Organic Syntheses* III, 47–9(1923).— $(\text{ClCH}_2)_2\text{CHOH}$ and NaOH give 76–81% of epichlorohydrin. C. J. WEST

Pentaerythritol (tetrahydroxymethylmethane). CHEMICAL LABORATORY, PICTON ARSENAL. *Organic Syntheses* IV, 53–6(1925).—Com. HCHO and AcI are condensed by $\text{Ca}(\text{OH})_2$, giving 50–4% of $\text{C}(\text{CH}_2\text{OH})_4$. C. J. WEST

***d*-Mannitol from *Gardenia turgida*.** M. O. FORSTER AND KESHAVIAH ASWATH NARAIN RAO. *J. Chem. Soc.* 127, 2176(1925).—The exudation from *G. turgida* has a pleasant odor, dissolves completely in cold H_2O with slight frothing, giving a pale brown viscous liquid; furfural is not produced by boiling with HCl , and tests for N, aldehydes and ketones were negative. The aq. soln., shaken with basic Pb acetate filtered and concd., deposited 40% of *d*-mannitol. C. J. WEST

Optical activity and the polarity of substituent groups. II. Menthyl esters of substituted acetic acids. H. G. RULE AND JOHN SMITH. *J. Chem. Soc.* 127, 2188–94(1925); cf. *C. A.* 18, 2326; 19, 33.—The rotatory powers of menthyl esters of the acids $\text{XCH}_2\text{CO}_2\text{H}$, where $\text{X} = \text{CN}, \text{CO}_2\text{H}, \text{OH}, \text{OMe}$ and OEt are reported. In all cases the observed rotations could be expressed within the limits of exptl. accuracy by a Drude equation of 1 term; the dispersion is in every case normal and simple. The substituents affect the rotatory power in the order $\text{CN} > \text{OH} > \text{OMe} > \text{OEt} > \text{CO}_2\text{H}$; the values undergo little change with temp. *l*-Menthyl methoxyacetate, b_{18} 141° , m 18° , d_4^{18} 1.0136, 0.9964, 0.9807, 0.9638 where $t = 20^\circ, 40.3^\circ, 60^\circ$ and 80° ; values for $[\alpha]$ are given for the D, yellow, green and violet for $20^\circ, 40^\circ, 60^\circ, 80^\circ$ and 90° . *l*-Menthyl ethoxyacetate, b_{18} 150° , d_4^{18} 0.9545, 0.9379, 0.9242, 0.9070 where $t = 20^\circ, 40.6^\circ, 58^\circ$ and 79.2° ; $[\alpha]$ as above. *l*-Menthyl glycolate, m 87.5° , $d_4^{94.3}$ 0.9469, $[\alpha]$ at 94.3° , -36.50° , -38.09° , -43.23° and -72.71° for the D, yellow, green and violet lines; rotations are also given for C_6H_6 and CHCl_3 solns. *l*-Menthyl cyanoacetate, $d_4^{91.3}$ 0.9406, $[\alpha]$ at 91.3° , -36.71° , -38.28° and -43.28° for the D, yellow and green lines; rotations in C_6H_6 and CHCl_3 are given. *l*-Menthyl H malonate, $d_4^{59.6}$ 1.0238, $d_4^{90.6}$ 1.0008; values for $[\alpha]$ are given for 59.5° and 90.5° for the 4 lines above and for a C_6H_6 soln. *l*-Menthyl glycolate, $d_4^{94.3}$ 0.9469, α -77.09° , -80.48° , -91.26° and -153.6° for the above 4 lines. The 2 types of group effect previously observed, the general effect visible in inductive capacity, acidic strength and chem. reactivity, and the polar effect, as deduced from the electronic theory and traceable in C_6H_6 substitution and electromagnetic rotation, are both to be found in optical activity. C. J. WEST

Bromination of lactic acid and calcium lactate in presence of light. JNANENDRA CHANDRA GHOSH AND KALIPADA BASU. *Quart. J. Indian Chem. Soc.* 2, 39–48(1925).—About $\frac{2}{3}$ of the reaction between lactic acid and Br takes place in the dark and thus the photochem. efficiency of light is not capable of very exact measurement; calcns. indicate that 4 quanta of energy activate 1 mol. of Br; Einstein's law of photochem. equiv. appears not to hold here. The reaction between Br and the Ca lactate is a monomol. one. Increasing the concn. of the salt increases the velocity const., while increase in the concn. of Br gives an irregular const., the reaction tending to degenerate into a 0 mol. one. About 0.75 of the velocity const. is due to dark reaction. When the concn. of the salt is $N/30$, about 2 quanta are necessary for the transformation of 1 mol. of salt; increasing the concn. of $N/15$ decreases the amt. to 1 quantum. C. J. WEST

β -Bromopropionic acid. E. C. KENDALL AND B. MCKENZIE. *Organic Syntheses* III, 25–6(1923).— $\text{HOCH}_2\text{CH}_2\text{CN}$ and HBr give 82–3% $\text{BrCH}_2\text{CH}_2\text{CO}_2\text{H}$. C. J. WEST

Ethyl β -bromopropionate. E. C. KENDALL AND B. MCKENZIE. *Organic Syntheses* III, 51–2(1923).—Crude $\text{BrCH}_2\text{CH}_2\text{CO}_2\text{H}$ in CCl_4 is boiled with EtOH and a catalyst (PhSO_3H), giving 85–7% of the Et ester. C. J. WEST

α -Bromocaproic acid. H. T. CLARK AND E. R. TAYLOR. *Organic Syntheses* IV, 9-10(1925).— $\text{Me}(\text{CH}_2)_4\text{CO}_2\text{H}$ is brominated in the presence of PCl_5 , giving 81-9% of $\text{Me}(\text{CH}_2)_4\text{CHBrCO}_2\text{H}$. C. J. WEST

Constitution of the α -eleostearic acid from Chinese wood oil and its isomer, β -eleostearic acid. J. BOESEKEN AND H. J. RAVENSWAY. *Proc. Acad. Sci. Amsterdam* 28, 386-9(1925).—See C. A. 19, 2475. E. J. C.

Methyleneaminoacetonitrile (α -hydroformamine cyanide). ROGER ADAMS AND W. D. LANGLEY. *Organic Syntheses* IV, 47-8(1925).— NaCN soln., added to techn HCHO and NH_4Cl at 0° , gives 64-74% of $\text{CH}_2=\text{NCH}_2\text{CN}$. C. J. WEST

Glycine. H. T. CLARK AND E. R. TAYLOR. *Organic Syntheses* IV, 31-3(1925).— $\text{CH}_2=\text{NCH}_2\text{CN}$ and HBr give $\text{H}_2\text{NCH}_2\text{CO}_2\text{H}$. HBr , from which the free base is liberated by $\text{C}_2\text{H}_5\text{N}$; yield, 31-7%. C. J. WEST

Isomerism in N -carbalkoxy derivatives of dipeptides which contain a β -amino acid. HERMANN LEUCHS AND PAUL SANDER. *Ber.* 58B, 1528-31(1925), cf. C. A. 2, 3078.—The isomerism of the carbethoxyglycylglycine esters, etc., which was ascribed to the change of a lactam into a lactim group, $\text{EtO}_2\text{CNHCH}_2\text{CONHCH}_2\text{CO}_2\text{Et} \rightarrow \text{EtO}_2\text{CNHCH}_2\text{C(OH)(NCH}_2\text{CO}_2\text{Et)}$, is also found in peptide derivs of β - NH_2 acids. *di-MeCH(NH_2)CH_2CO_2H* (I) with ClCO_2Me in aq. $\text{NaOH-Na}_2\text{CO}_3$ gives 85-97.5% of *N*-carbomethoxy β -aminobutyric acid (II), m. $90-1^\circ$ (cor.), converted by SOCl_2 at 50° into the chloride, light yellow oil of penetrating odor, which with NH_3 in Et_2O gives the amide (0.85 g. from 1 g. II), m. $141-2^\circ$, and with 2.2 mols. $\text{PhNHCH}_2\text{CO}_2\text{Et}$ in Et_2O yields *Et* carbomethoxy β -aminobutyryl-*N*-phenylglycine, $\text{MeO}_2\text{CNHCHMeCH}_2\text{CONPhCH}_2\text{CO}_2\text{Et}$ (III) (6.0 g. from 3.2 g. II), m. $94.5-5.5^\circ$. Shaken 1 hr with 1.1 mols. *N* NaOH , III yields the free carbomethoxyglycine, faintly yellow viscous oil, isolated as the NH_4 salt, $\text{C}_9\text{H}_{13}\text{O}_5\text{N}_3$ (1.3 g. from 1.6 g. III). When heated 6 hrs. at 100° with 3.3 mols. *N* KOH , on the other hand, III, which, from its structure, cannot isomerize as above, consumes no alkali and there is obtained amorphous β -aminobutyryl-*N*-phenylglycine. In the same way with $\text{H}_2\text{NCH}_2\text{CO}_2\text{Et}$ is obtained 90% *Et* carbomethoxy- β -aminobutyryl-glycine (α -series) (IV), m. $99-100^\circ$; free carbomethoxyglycine (V), from IV with 1.1 mols. alkali at room temp., m. $135-6^\circ$; *Me* ester (α -series) (0.5 g. from 0.5 g. V with dil. MeOH-HCl at 40°), m. $101-3^\circ$, amide (α -series) (0.8 g. from 1 g. IV with $\text{NH}_3\text{-MeOH}$), m. $118-9^\circ$. Heated 4 hrs. at 100° with 2.2 mols. *N* KOH , 1 g. IV uses up 2 mols. alkali and yields 0.8 g. *N'* β -aminobutyryl-glycine-*N*-carboxylic acid (β -series), yellow oil, converted by 4% HCl in MeOH into the *di-Me* ester, $\text{MeO}_2\text{CNHCHMeCH}_2\text{C(OH)(NCH}_2\text{CO}_2\text{Me)}$, isomeric with the above α -ester, m. $84-5^\circ$, depresses the m. p. of its isomer to about 65° , gives with $\text{NH}_3\text{-MeOH}$ at 20° β -ureidobutyryl-glycinamide (β -series) (68% yield), tables, prisms or needles with 1 H_2O , m. $95-100^\circ$, solidifies and m. again (anhyd.) 182° . *Et N'*-[carbethoxyglycyl]- β -aminobutyrate (α -series) (12 g. from 15 g. of the *Et* ester of I and $\text{EtO}_2\text{CNHCH}_2\text{COCl}$), m. $56-8^\circ$, gives with 1.1 mols. alkali at room temp. the free acid, isolated as the hygroscopic NH_4 salt, $\text{C}_9\text{H}_{13}\text{O}_5\text{N}_3$, hydrated tables or anhyd. prisms which decomp. on drying at high temps. *N'*-Glycyl- β -aminobutyryl-*N*-carboxylic acid (β -series), from the above α -di *Et* ester with NaOH at 100° , isolated as the β -di-*Et* ester (yield, 72%), m. $103-4^\circ$, which with $\text{NH}_3\text{-MeOH}$ at 100° gives ureidoacetyl β -aminobutyramide (β -series), leaflets with 1 H_2O , sinters $95-100^\circ$, m. about 172° (decomp.). Carbethoxyglycyl- β -aminobutyramide (α -series), obtained in the same way in 0.55 g. yield from 0.9 g. of the α -ester, m. $130-1^\circ$. The only difference observed in the isomerism phenomena of the peptides derived from α - and from β NH_2 acids is that the lactim forms (β -series) of the latter do not, like certain of those of the former, change into azlactones. C. A. R.

Hydrazine sulfate. ROGER ADAMS AND B. K. BROWN. *Organic Syntheses* II, 37-40(1922).—Prepn. from NH_3 and NaOCl . C. J. WEST

α -Aminocaproic acid. C. S. MARVEL AND V. DU VIGNEAUD. *Organic Syntheses* IV, 3-4(1925).— $\text{Me}(\text{CH}_2)_4\text{CHBrCO}_2\text{H}$ and NH_3 give 62-7% of $\text{Me}(\text{CH}_2)_4\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$. C. J. WEST

L-Cystine. R. A. GORTNER AND W. F. HOFMAN. *Organic Syntheses* V, 39-41(1925).—Directions are given for the hydrolysis of human hair and the isolation of l-cystine in 5-5.3% yields. The yield from sheep's wool is about 2.6%. C. J. WEST

Diallylamine. E. B. VLIET. *Organic Syntheses* V, 43-4(1925).— $(\text{CH}_2=\text{CHCH}_2)_3\text{N}$, heated with H_2SO_4 for 6 hrs., gives 80-6% of $(\text{CH}_2=\text{CHCH}_2)_2\text{NH}$. C. J. W.

Diacetone alcohol. J. B. CONANT AND NEAL TUTTLE. *Organic Syntheses* I, 45-7(1921).—Prepn. of $\text{Me}_2\text{C(OH)CH}_2\text{Ac}$ from Me_2CO by boiling with Ba(OH)_2 ; 71% yields. C. J. WEST

Keto-enol tautomerism. V. The desmotropic γ -methylacetylacetones. H. P.

KAUFMANN AND J. LIEPE. *Ber.* **58B**, 1560–3(1925); cf. *C. A.* **19**, 1565.—As in the case of $(\text{AcCHCO}_2\text{Et})_2$ (*C. A.* **17**, 379), so in that of γ -methylacetylacetone (I) in the Meyer method for the detn. of enols both direct and indirect titration give the same values if H_2O is excluded by using alc. NaI instead of aq. KI (enol in 0.1 *N* soln. in abs. alc. after 3 days: direct titration 43, indirect with aq. KI 17–23, indirect with alc. NaI 42%). But H_2O neither disturbs the splitting off of HBr nor does it attack the I, nor do $2\text{-C}_{10}\text{H}_7\text{OH}$ or the HBr or I liberated produce any disturbance, so that provisionally it can only be assumed that the presence of H_2O retards the sepn. of the I; under certain conditions the great sensitiveness of I or of its Br derivs. towards H_2O also plays a role. Attempts to obtain from the I, b.p. 60–5°, the pure enol by cooling the CS_2 soln. in $\text{Et}_2\text{O}-\text{CO}_2$ gave needles contg. 32.9% enol. Decompn. of the Na salt in cold Et_2O with H_2SO_4 gave an oil, m. 7°, with 99% enol. Fractionation of I by the "aseptic distill." method of Meyer (*C. A.* **15**, 2640) finally gave a residue with 93% keto form.

C. A. R.

An occurrence of *d*-glucuronic acid in plant fibers. C. G. SCHWALBE AND G. A. FELDTMANN. *Ber.* **58B**, 1534–9(1925).—A bleached straw cellulose pulp (400 g. dry wt., contg. 16.13% furfural) was autoclaved 1.5 hrs. at 130° in 7 l. of 0.5% NaOH, and the filtrate, which was only faintly alk. to litmus, was treated with H_2SO_4 until it contained about 0.5% free acid and autoclaved 2.5 hrs. at 135°; the ext. contained only 4.38% of the original furfural and the remaining cellulose 66.49%, 29.13% having been destroyed. The cooled liquid, which gave a distinct naphthoresorcinol reaction and at once reduced Fehling soln. even in the cold, was neutralized to Congo with BaCO_3 , filtered and pptd. with $\text{Pb}(\text{OAc})_2$; from the ppt., after decompn. with H_2S , was obtained a small amt. of crystals which in 12% HCl gave a positive furfural reaction (reddening of PhNH_2 AcOH paper) and naphthoresorcinol reaction and were identified as *d*-glucuronic acid (I) through the cinchonine salt, m. 202°, $[\alpha]_D^{20}$ 139.9°. For quant. detns. of the I, the amt. of CO_2 split off by 12% HCl was measured. To destroy carbonates present in the cellulose 100 g. of it was autoclaved 2 hrs. at 135° in 2 l. 1% H_2SO_4 ; the cellulose now remaining contained 0.1365 g., the ext. 0.5743 g. glucurone (II); the amts. of furfural were, resp., 7.9744 and 7.1180 g., i. e., about 1 g. had been destroyed during the cooking. In the alk. cooking described above for the qual. detection of I, the ext. from 100 g. cellulose contained 0.4950, the remaining cellulose 0.5621 g. II (the latter was first boiled 1 hr. with 1% HCl to get rid of the free alkali and carbonate remaining from the previous treatment). Cellulose previously boiled 1 hr. with 1% HCl gave 1.07% II. In a no. of other plant raw materials and celluloses, from which I was not actually isolated, the following % of CO_2 were obtained: wheat straw 1.02; rye straw 1.03; pine wood 0.74 (shavings), 0.75 (raspings), 0.78 (raspings, previously treated with 1% HCl); unbleached alkali wood cellulose 0.60 (Na_2S), 0.19 (NaOH), 0.16 (sulfite).

C. A. R.

Pyruvic acid. J. W. HOWARD AND W. A. FRASER. *Organic Syntheses* IV, 63–4 (1925) — $[\text{CH}(\text{OH})\text{CO}_2\text{H}]_2$ and KHSO_4 , heated at 210–20°, give 50–5% of AcCO_2H .

C. J. WEST

The catalytic decomposition of pyruvic acid. ERICH MÜLLER AND FRIEDRICH MÜLLER. *Z. Elektrochem.* **31**, 45–6(1925).—At 100°, aqueous solns. of AcCO_2H (I) are rapidly decompd. to CO_2 and AcH by the metals Os, Pd, Ru, while without a catalyst practically no decompn. occurs. Os causes the most rapid decompn., more rapid in 50% than in 20% soln. of I.

M. A. YOUTZ

Condensation products of ethyl acetoacetate. I. A new compound of glyoxal and ethyl acetoacetate, formylmethylenebisacetoacetate ester. E. S. WEST. *J. Am. Chem. Soc.* **47**, 2780–9(1925) — Compds. of $\text{AcCH}_2\text{CO}_2\text{Et}$ with sugars or their intermediate oxidation products are of interest because of their possible relation to the "ketolytic" reaction or to antiketogenesis in the animal body. $(\text{CHO})_2$ and $\text{AcCH}_2\text{CO}_2\text{Et}$ in approx. neutral soln. at 20° give 15–20% of *Et* formylmethylenebisacetoacetate (I), m. 109–10°; mol. wt. in boiling AcOEt , 303.6, 312.9 (calcd. for $\text{C}_{14}\text{H}_{20}\text{O}_7$, 300.2); aq. alkali causes resinification; it reduces Tollen reagent in the cold and Fehling and Benedict solns. when heated; it quickly decolorizes neutral KMnO_4 in the cold and absorbs Br in CCl_4 with evolution of HBr. I does not form an addn. product with NaHSO_3 and does not restore the color of Schiff reagent. Hydrazines give smearable products. NH_2OH gives the aldoxime of 4,6-dicarbethoxy-5-formyl-3-methyl- Δ^2 -cyclohexenone, m. 94–5° (decompn.); H_2O and NH_3 are evolved when heated at 100° and 20–30 mm., also when dried over H_2SO_4 in *vacuo* for 18 hrs., giving a compd. m. 140° (decompn.); it does not resinify with alkali and does not reduce Tollen, Benedict or Fehling solns. Color reactions of I with FeCl_3 , $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$, α - and $\beta\text{-C}_{10}\text{H}_7\text{OH}$, etc., are given. Dil. alkali eliminates 1 mol. CO_2 from I. The oily mother liquor from I contains *Et* α' -acetoace-

tate- α -methyl- β -furancarboxylate, the ether of Et β' -hydroxy- α -methyl- γ -furancarboxylate, previously obtained by Polonowski (*Ann.* **246**, 27(1888)) and Et β -hydroxy-crotonate.

C. J. WEST

A new method for the preparation of α -alkyllevulic acids. H. GAULT AND T. SALOMON. *Ann. chim.* [10] **2**, 133-209(1924).—The first attempted method was from $\text{MeCOCH}_2\text{CH}(\text{CO}_2\text{R})_2$ (I) by alkylation of its Na deriv. followed by sapon. and elimination of CO_2 to yield the desired levulic acids $\text{MeCOCH}_2\text{CHRCO}_2\text{H}$ (II); the alkyl derivs. of I could not be purified and their sapon. did not go well, and hence the method was abandoned. By the action of $(\text{NH}_2)_2$ on I methylpyridazinonecarboxylic ester (III) is formed, whose Na deriv. can readily be alkylated, after which HCl and heat liberate $(\text{NH}_2)_2$ and CO_2 with the formation of the desired II compds.; this method is that finally used. $\text{MeCOCH}_2\text{CH}(\text{CO}_2\text{Et})_2$ (IV), prepd. from MeCOCH_2Br (whose prepn. is described) b_{10} 145-7°; its phenylhydrazone, m. 109°, semicarbazone, m. 128-30°, the (di-IV) hydrazone, Δ 43°, being a by-product in the prepn. of III; no oxime or NaHSO_3 compd. could be prepd. Various alkyl derivs. of IV were prepd. from its Na deriv. and RI, in alc., the reaction being carried out under various conditions; the *Me* deriv. could not be prepd.; the *Et* deriv. was obtained in 80% yield, its phenylhydrazone, m. 99-100°, semicarbazone, m. 126-7°; the *iso-Bu* deriv., 72% yield, its phenylhydrazone, m. 72-3°, semicarbazone, m. 128-9°. Various *alkylacetylmalonic acids* (V), were prepd. by sapon. of the foregoing esters or of the corresponding III deriv.; the *unsubstituted acid*, m. 145-6°, its phenylhydrazone, m. 127-8°, semicarbazone, 176-8°. The *Et* deriv. of V (60% yield from the ester), m. 122-3°, its phenylhydrazone, m. 160° or 136° (2 preps.), its semicarbazone, m. 176-7°. The *iso-Bu* deriv. of V could not be isolated in appreciable amts because of decompn. The following *substituted ethyl 6-pyridazinone-5-carboxylates* (VI) were prepd. from I and $(\text{NH}_2)_2$; 3-*Me*, m. 79-80°, its hydrazide, m. 53°, being formed if twice the theoretical amt of $(\text{NH}_2)_2$ is used; 3,5-di-*Me*, m. 43°; 3-methyl-5-ethyl, m. 70-2°; 3-methyl-5-isobutyl, m. 80-1°; all of the foregoing were obtained in approx. 40% yield based on I. From them by the action of cold dil. alkali the corresponding *substituted 6-pyridazinone-5-carboxylic acids* (VII) were obtained as follows; 3-*Me*, 50% yield, m. 130°; 3,5-di-*Me*, 95%, m. 153-4°; 3-methyl-5-ethyl, 90%, m. 137°; 3-methyl-5-isobutyl, yield 90%, m. 122-4°. If in place of cold dil. alkali VI be sapond. with hot HCl , the corresponding α -alkyllevulic acids are obtained in the following yields (based on VI); *unsubstituted*, 75%, m. 31°, b_{15} 152-4°, semicarbazone, m. 187°; *Me*, 60%, b_{13} 144 5°, semicarbazone, m. 189 90°, Fl , 65%, b_{13} 151-2°, semicarbazone, m. 171-2°; *iso-Bu*, 55%, b_{30} 171-3°, semicarbazone, m. 188-9°.

WM. B. PLUMMER

Oxalic acid (anhydrous). H. T. CLARKE AND ANNE W. DAVIS. *Organic Syntheses I*, 67-70(1921).—Prepn. of anhyd $\text{C}_2\text{H}_2\text{O}_4$ from the crystd. acid by dehydrating with CCl_4 .

C. J. WEST

Ethyl oxalate. H. T. CLARKE AND ANNE W. DAVIS. *Organic Syntheses II*, 23-6 (1922).—Esterification of crystd. $(\text{CO}_2\text{H})_2$ by EtOH in the presence of CCl_4 . Yield, 80-4%.

C. J. WEST

Ethyl oxalate. JOSEPH KENVON. *Organic Syntheses V*, 59-61(1925).—Cryst. $(\text{CO}_2\text{H})_2$ is dehydrated by heating on the steam bath for 6-8 hrs. and esterified by EtOH , the H_2O formed in the process being removed from the EtOH by K_2CO_3 ; yield, 80-90%.

C. J. WEST

Precursory compounds in the esterification of oxalic acid with phenols. FRITZ FEIGL AND RIVA KOBILANSKY. *Ber.* **58B**, 1483 8(1925).—Assuming that, like the addn. products with ethers, aldehydes and ketones, phenols (B) add to $(\text{CO}_2\text{H})_2$ (A) at the O of the C:O groups and considering the fact that acid Ph esters of $(\text{CO}_2\text{H})_2$ are unknown, it yet seems quite probable that compds. of the type 2B.A should be capable of existence; the esterification of $(\text{CO}_2\text{H})_2$ might then be considered as proceeding through the following series of reactions (D = dehydrating agent): $2\text{B.A(I)} \rightarrow 2\text{B.A(II)} \rightarrow 2\text{B.A.D(III)} \rightarrow (\text{CO}_2\text{Ph})_2 + \text{H}_2\text{O}$. Compds. of type I have been obtained with PhOH , *p*-cresol and *p*- $\text{C}_6\text{H}_4(\text{OH})_2$, and with PhOH , α - and β - $\text{C}_{10}\text{H}_7\text{OH}$ and *ar*-tetrahydro- β -naphthol compds. of type II which by POCl_3 are converted directly into the corresponding esters; no compd. of type III could be isolated. The mols. in these precursory compds. are probably held together by satn. of secondary valences between the H atoms of the phenols and the doubly bound O atoms of the $(\text{CO}_2\text{H})_2$; phenol ethers (PhOMe , PhOEt , PhOPh) do not form such addn. products, while oxalic esters do. Hydrogenated phenols (cyclohexanol, *al*-tetrahydro- β -naphthol) show no more additive power towards $(\text{CO}_2\text{H})_2$ than do alcs.; the double bonds in the phenols are therefore decisive factors in the stability of these precursory compds. There is no relation between the m. ps. of the precursory compds. and the stoichiometrically equiv.

condensation products except that they are always lower than that of the highest melting constituent. The precursory compds. and the condensation products have different cryst. forms. All the compds. are decompd. into their components by H_2O . *Phenol-oxalic acid*, B.A. from 1 mol. each of the components kept fused for 1 hr., seps. from AcOH in rhombic or trigonal crystals, m. 98°. *Bisphenol-oxalic acid*, 2B.A. from $(CO_2H)_2$ and somewhat more than 2 mols. PhOH refluxed 3 hrs., rhombic cryst. meal, m. 127°. $(CO_2Ph)_2$, obtained in 50% yield from 1 mol. $(CO_2H)_2$, 2 mols. PhOH and 2 mols. $POCl_3$ in C_6H_5N at 0°, monoclinic or triclinic, m. 130°, also obtained from 2B.A. with $POCl_3$ in C_6H_5N . *Bisphenol-di-Ph oxalate*, from $(CO_2Ph)_2$ and more than 2 mols. PhOH refluxed several hrs. in CCl_4 , m. 106°. *Bisphenol-di-Me oxalate*, m. 123°. *Bis-ar-tetrahydro-β-naphthol-oxalic acid*, rhombic, m. 155°. *Bis-ar-tetrahydro-β-naphthyl oxalate*, obtained in 50% yield from 1 mol. each of the naphthol and acid in C_6H_5N , monoclinic, m. 149°. *Bis-ar-tetrahydro-β-naphthol-di-Me oxalate*, m. 147° (yield, very small); *di-Ph oxalate*, m. 122° (yield, small). *Bis-β-naphthol-oxalic acid*, obtained almost quant. from the components, refluxed in AcOH, m. 167°; α-naphthol isomer, m. 163° (yield, very small). *Di-β-naphthyl oxalate*, obtained in about 50% yield from the precursor, rhombic, m. 189°. *p-Cresol-oxalic acid*, obtained in small yield from the components on the H_2O bath, m. 56°. *Di-p-tolyl oxalate*, m. 147°. *Hydroquinol-oxalic acid*, m. 197°. C. A. R.

Action of methyl cyanofornate on organomagnesium compounds. H. FINGER AND R. GAUL. *J. prakt. Chem.* 111, 54-61 (1925). $-NCCO_2CH_3$ and 3 mols. $MeMgI$ give a very small yield of $AcCMc(OH)Me$, b. 140-2°. $EtMgBr$ gives 58% of $EtCOC(OH)Et_2$, b. 68-70°. $PhMgBr$ gives a mixt. of phenylbenzoin and Ph_3COH . α- $C_{10}H_7MgBr$ gives about 50% of the *ketimide*, $C_{10}H_7C(=NH)C(OH)(C_{10}H_7)_2$, m. 150.1° (decompn.), isolated as the *HBr salt*, yellow, m. 205-10° (decompn.); *HCl salt*, light yellow, m. 185-90°; *HNO₃ salt*, yellow, m. 135-6°; *picrate*, bright yellow, m. 165-6°. Moderately concd. KOH and the HBr salt appear to give a *hydrate* of the imide, m. 135-8° (decompn.). C. J. WEST

Ethyl butylmalonate. ROGER ADAMS AND R. M. KAMM. *Organic Syntheses IV*, 11-12 (1925). $-CH_2(CO_2Et)_2$, $EtONa$ and $BuBr$ give 80-90% of $BuCH(CO_2Et)_2$. C. J. WEST

The electrosynthesis of *n*-duotricontanedicarboxylic acid. D. A. FAIRWEATHER. *Proc. Roy. Soc. Edinburgh* 45, 283-5 (1925).—Diethylhexadecanedicarboxylate is obtained by electrolysis of Na Et sebacate and this compd. is half hydrolyzed by NaOH. A soln. of 30 g. in 3 l. of alc. is cooled to 5° and sufficient alc. NaOH added to half sapon. only 20 g. The temp. is kept at 5° for 3 days and then at 10-15° for a week, after which time neutrality is reached. Yield of di-Na salt, 5 g., of Na Et salt, 10 g. *II Et hexadecanedicarboxylate* (m. 71°) is pptd. from a soln. of the Na salt by HCl and recrystd. from MeOH. A soln. of 10 g. of the Na salt in 45 cc. of water sets to a soapy mass at about 40° and cannot be electrolyzed on account of frothing. Alc. (4 cc.) is therefore added and a current of 2-3 amp. passed in for 3 hrs. at 70-75°. Water and alc. are added from time to time to replace loss by evapn. The operation is conducted in a beaker, with Pt electrodes. The oil thus obtained contains 5 g. of *di-Et duotriacontanedicarboxylate*, m. 80°. *Free acid*, m. 123°, is obtained by hydrolysis of the ester. R. C. F.

Rotation-dispersion of optically active compounds. Dimethoxysuccinates and pyridine. T. S. PATTERSON AND J. D. FULTON. *J. Chem. Soc.* 127, 2435-44 (1925).—The difference between the rotation values for 2 colors of light—dispersion—is directly proportional to either value, if calcd. from the point of intersection for these 2 colors—the rational zero. Using the rational zero, a dispersion coeff. may be arrived at which shows very fair constancy under widely differing conditions and may in future prove to be definitely characteristic of a particular substance or group of substances. Because of exptl. difficulties, T-R curves for most active compds. have been ascertained for only a comparatively short range; it has been suggested that these might be constructed by piecing together T-R curves of solns. of the active compd. in question or derivs. of it. The question arises whether the dispersion coeff. derived from such T-R curves would have the same value as for the mother substance, when calcd. from the rational zero. To answer this, *dibenzyl d-dimethoxysuccinate*, b_D 180-90°, n_D^{19} 1.5321, d 1.1730, 1.1551, 1.1320, 1.1064 at 16.4°, 41°, 70.75° and 100°, was studied. The values for $[\alpha]$ were detd. for wave lengths 6716.3, 6234.3, 5790.3, 5460.7, 4959.7, 4358.3 at temps. from 0° to 174.5° (7 in all), in quinoline from 0° to 100°, in $o-O_2NC_6H_4Me$ from 0° to 100°, in $C_6H_2Br_4$ from 0° to 98.8°, in $m-C_6H_4Me_2$ from 16.9° to 98.°, in C_6H_5N from 0° to 99°, in Me_2CO from 0° to 46.6° and for the Me deriv. in quinoline from 0° to 99.6°, the d of the solns. also being detd. Benzyl tartrate in quinoline was also studied. All these curves are of a similar form, although the rotation may be lower or higher.

The dispersion coeff., for the rational zero $[\alpha] = 9^\circ$, is 0.8642, differences occurring in the 3rd decimal place. In the case of Et tartrate, between temps. of 40° and 140° , the rational zero was found to be 7.92° and the mean value of the dispersion coeff. was 0.8660. These results lend support to the idea that even when data are taken from T-R curves apparently on different sides of the max. rotation, the rational dispersion coeff. shows something like a real constancy. Nicotine, $[\alpha]_D^{20}$ 168.02° and 167.78°, d_4^{20} 1.0095 and 1.0100 (2 samples), was then studied. This was used alone, and in HCONH_2 , $\alpha\text{-O}_2\text{NC}_6\text{H}_5\text{Me}$, quinoline, $\alpha\text{-C}_{10}\text{H}_7\text{Br}$, AcOEt , H_2O and excess of H_2SO_4 , the d and rotatory power for the above-named wave lengths being detd. from 0° to 100° . The change of rotation of nicotine with temp. is only slight but the shape of the curve suggests the occurrence of a min. at a temp. probably in the neighborhood of 170° or thereabouts. Its behavior is normal. When dispersion coeffs. are calcd., using the rational zero 3° , the mean value is found to be 0.8674. C. J. WEST

Stereochemistry of the tetrahedral carbon atom. II. Configuration of the diaminosuccinic acids. RICHARD KUHN AND FRITZ ZUMSTEIN. *Ber.* 58B, 1420-32 (1925); cf. C. A. 19, 2177. From the fact that the more difficultly sol. (I) of the 2 optically inactive α,β -diaminosuccinic acids gives *meso*-tartaric acid with HNO_2 and the more easily sol. form (II) yields chiefly racemic acid, Farchy and Tafel concluded (*Ber.* 26, 1985 (1893)) that I and II are the *meso*- and *dl*-forms, resp., and although their method of establishing the configurations cannot be considered as being conclusive, since the replacement of the NH_2 groups by OH proceeds in steps and it is conceivable that the intermediate hydroxyasparaginic acid might undergo a Walden inversion, K. and Z. now show that they were right, for the di-Bz deriv. of II can be resolved into optical antipodes by means of morphine. The 2 acids are sep'd from each other by fractional pptn. with H_2SO_4 and the I is purified by repeated pptn. from NaOH with AcOH and the II by pptn. from HCl with NaOH ; yields, about 120 and 80 g., resp., from 1 kg. $[\text{C}(\text{C}_6\text{H}_5)_2\text{N}(\text{H})\text{CO}_2\text{H}]_2$. II seps. in prisms with 1 H_2O , which it loses at 130° *in vacuo* and quite rapidly absorbs again from the air. Di-Bz deriv. of I, m. $212-3^\circ$ (decompn.); of II, with 1 H_2O , m. 161° (decompn.). Di-HCl salt of I, decomp. $186-7^\circ$, difficultly sol. in cold H_2O ; mono HCl salt of II, decomp. about 200° , easily sol. in cold H_2O . Soly. of I in 100 cc. concd. H_2O at 25° , 3.1 mg.; of II, 20 times greater. The 2 acids do not give with KI HgI_2 and phosphotungstic acid the pptn. reactions characteristic of diaminomonocarboxylic acids; with CuSO_4 they give a deep blue color only after addn. of alkali; the ninhydrin reaction is positive; with $\text{Hg}(\text{NO}_3)_2$ and alkalis they ppt. yellow HgO , which is blackened (reduction) on boiling, considerably more rapidly and completely by I; they do not reduce Liebig-Knapp's alk. Ag soln.; in alk. soln. with Millon's reagent they form a thick white ppt. which is very difficultly sol. even on heating. From 12 g. of the di-Bz deriv. of II and 10.4 g. morphine in 1060 g. boiling H_2O there seps. after 18 days at 0° about 15 g. of morphine *d-dl*[benzoylamino]succinate, $\text{C}_{20}\text{H}_{23}\text{O}_6\text{N}_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, decomp. $198-201^\circ$, loses $31\frac{1}{2}\text{H}_2\text{O}$ at 130° *in vacuo*; free acid, $\text{C}_{18}\text{H}_{19}\text{O}_6\text{N}_2 \cdot \text{H}_2\text{O}$, m. $163-4^\circ$, $[\alpha]_D^{20}$ 106.5° (0.1 N NH_4OH). The filtrate from the *d*-salt, decompd. with $\text{NH}_4\text{OH} \cdot (\text{NH}_4)_2\text{CO}_3$ and acidified with H_2SO_4 , yields 4 g. of the *l*-acid, m. $163-4^\circ$ (decompn.), $[\alpha]_D^{20} -104.2^\circ$ (0.1 N NH_4OH). C. A. R.

Glutaric acid. C. S. MARVEL AND W. F. TULEY. *Organic Syntheses* V, 69-70 (1925).—Hydrolysis of $\text{NCCl}_2\text{CH}_2\text{CH}_2\text{CN}$ with HCl gives 83-5% $\text{CH}_2(\text{CH}_2\text{CO}_2\text{H})_2$.

C. J. WEST

Adipic acid. J. F. THORPE AND G. A. R. KON. *Organic Syntheses* V, 9-11 (1925).—Oxidation of cyclohexanol by boiling concd. HNO_3 gives 55-6% adipic acid; the loss on purification is not greater than 10%.

C. J. WEST

Configuration of α,α' -dibromodibasic acids. IV. The α,α' -dibromoglutaric acids. H. R. ING AND WM. H. PERKIN, JR. *J. Chem. Soc.* 127, 2387-99 (1925); cf. C. A. 19, 246. —*Me meso*-dibromoglutarate (I), m. 45° ; the *dl*-ester (II), b_{10} $113-5^\circ$. *Me α,α' -diiodoglutarate* (III), m. 75° ; there is also a liquid form, pale yellow oil, gradually turning brown because of liberation of I. Treating 7 g. of II with 0.25 g. Na in 20 cc. EtOH causes the crystn. of 5 g. I in 10 min.; with larger amts. of MeONa , NaBr ppts and *Me* bromocyclopropanedicarboxylate is formed. At the ordinary temp. III is rapidly converted by MeONa into the *Me* ester (not analyzed) of 1-iodocyclopropane-1,2-dicarboxylic acid, m. $176-7^\circ$. $\text{CHNa}(\text{CO}_2\text{Et})_2$ and the Et dibromoglutarate give a mixt. of $\text{CH}_2(\text{CO}_2\text{Et})_2$, Et 1-bromocyclopropane-1,2-dicarboxylate and Et cyclobutane-1,2,2,3-tetracarboxylate, b_{12} $195-8^\circ$ (yield, about 50% of the original ester). There also is formed a thick oil, $\text{C}_{14}\text{H}_{15}\text{O}_7$, which could not be distd. without decompn., and is considered to be a bridged-ring ester. The condensation with a mixt. of I and II gives a mixt. of solid *Me cyclobutane-1,2,2,3-tetracarboxylate*, m. 78° , and a liquid ester, b_{16} $193-5^\circ$ (the

total yield was about 30%). In C_6H_6 the total yield is about 70–80%. **I** in MeOH treated with MeONa, gives *Me 1-bromocyclopropane-1,2-dicarboxylate*, b_{15} 134–5°; when this is treated with $CHNa(CO_2Me)_2$ in MeOH, there results a *Na deriv.*, $C_{11}H_{11}O_7Na$, giving the *compd.* $C_{11}H_{12}O_7$, m. 207°, which may be CH_2 $\begin{matrix} \diagup C(CO_2Me).CO \\ \diagdown C(CO_2Me).CHCO_2Me. \end{matrix}$

Condensation of Et dibromoglutarate with $NCCH_2CO_2Et$ and EtONa gives *Et 2-cyanocyclobutane-1,2,3-tricarboxylate*, b_{20} 210–5°, which on hydrolysis with cold EtOH-KOH gives a tri-K salt of an amide-acid, $C_8H_6O_7NK_3$; further hydrolysis gives cyclobutanetricarboxylic acid. The corresponding *Me ester* (from **I** or **II**), m. 111–2° or (liquid form) b_{12} 185–90°; the proportion of solid to liquid isomer formed from **I** was 1:2, from **II**, 1:3. *Et 2-benzoylcyclobutane-1,2,3-tricarboxylate*, $b.$ 230–40° (yield, 30%). *Et 2-acetylcyclobutane-1,2,3-tricarboxylate*, b_{18} 195° (30% yield). The resolution of *trans*-cyclobutane-1,2,3-tricarboxylic acid with quinine is described, showing that the acid, m. 172°, has the *dl*-configuration. C. J. WEST

Addition of cyanoacetic ester to esters of glutacetic and β -methylglutacetic acids. E. P. KOHLER AND G. H. REED. *J. Am. Chem. Soc.* **47**, 2803–11 (1925).— $NCCH_2CO_2Me$ can be added without difficulty to di-Me glutaconate, the resulting product b_{11} 203–5°, b_2 172°, hydrolyzed by HCl to $CH(CH_2CO_2H)_2$, m. 126°; the dianilic acid, m. 206° (Ingold reported 192°), thus the mode of addn. is the same as that to any other α,β unsatd. ester. There is no appreciable difference in the case with which $NCCH_2CO_2Et$ combines with the esters of the "normal" and labile forms of β -methylglutacetic acid; the addn. product from both esters is the same and the mode of addn. is that of α,β unsatd. esters. In the hydrolysis of the addn. product, there first results an *imido acid*, $C_8H_{11}O_4N$, m. 155°, hydrolyzed by alkali to $MeC(OH_2CO_2H)_2$, m. 169°. The addn. reactions of glutacetic acids cannot be properly used to support the view that the "normal" forms of these acids cannot be represented by conventional formulas. C. J. WEST

An X-ray examination of maleic and fumaric acids. KATHLEEN YARDLEY. *J. Chem. Soc.* **127**, 2207–19 (1925).—This study was undertaken primarily to det. whether the planosymmetry and centrosymmetry usually ascribed to maleic and fumaric acids, resp., have any actual existence in the cryst. state. The results of the X-ray examn. of maleic acid show that the crystals belong to the space group C_{2h}^2 ; since there are 4 mols. in the unit cell, the maleic acid mol. must be asym.; the planosymmetry usually ascribed to maleic acid from chem. considerations has, therefore, no existence in the cryst. state. Various projections of the unit cell are shown. Fumaric acid crystallizes in the triclinic system, a, b, c = 0.504, 1.0413, α 90° 40', β 88° 30', γ 89° 48'. Its d is 1.625 g./cc. There are 6 mols. of $C_2H_2(CO_2H)_2$ in the unit cell. C. J. WEST

Applications of thallium compounds in organic chemistry. II. Titrations. G. H. CHRISTIE AND R. C. MENZIES. *J. Chem. Soc.* **127**, 2369–73 (1925), cf. *C. A.* **18**, 2328.—The following thallous salts were prepd. by titrating the acids with standard $TlOH$ soln. and phenolphthalein; the accuracy of the titrations is the same as in the cases of NaOH and KOH, the values for the equiv. wts. of the acids being correct to 3 significant figures. *Fumarate*, m. 268° (decompr.); *maleate*, m. 161–6°; *succinate*, m. 246–8°; *phthalate*, m. 268–70°. The palmitate behaves as an anisotropic liquid between 116 and 170°. *Tetrathallium tartrate* deposits when a soln. of the acid and $TlOH$ is made alk. *2-Methylpyridine-3,4,6-tricarboxylate*, crysts. with 1 H_2O . *Et acetoacetate*, m. 91–2°; *benzoylacetone*, yellow, m. 103–5°; *phenol*, m. 231–5°; *m-cresol*, m. 187°; *resorcinol* *Me ether*, m. 146–8°, *guaiacol*, m. 160–1°; α -*naphthol*, m. 180–90°; *vanillin*, m. 193–201°. C. J. WEST

The cyclization of asparagine. Derivatives of aminosuccinimide. E. CHERBULIEZ AND L.-F. CHAMBERS. *Helvetica Chim. Acta* **8**, 395–403 (1925).—*Benzoylasparagine* (**I**) (5 g.) heated to 200°, the residue extd. with EtOH, this soln. cooled, the crystals filtered off (**II**), and the soln. concd. gave 61% of *benzoylamino succinimide* (**III**), m. 225–6°, sol. in 60 parts boiling EtOH, or in 90 parts H_2O , insol. in Et_2O , C_6H_6 and ligroin. The aq. soln. is acid to litmus and does not dissolve $Cu(OH)_2$, but **III** dissolves easily in NaOH. The H_2O soln. is optically inactive. The Na deriv. is obtained by treating **III** in EtOH with NaOH and evapg. the soln. It is sol. in 5 parts EtOH. Acid NH_4 benzoate (0.5 g.), m. 183–5°, sublimes when 5 g. of **I** are heated. The crystals, **II**, consist of *benzoylaspartodiamide*, $H_2NOCCH_2CH(NH_2)CONH_2$. With strong alk. NaOBr, **III** is converted to **I**, solely by the action of the alkali. **III** with CH_2O gives 92% of *N-hydroxymethylbenzoylamino succinimide* (**IV**), m. 155–9°, sol. in 14 parts of boiling EtOH, slowly decomp. on standing in air to **III** and CH_2O again. **IV** with PCl_5 in $CHCl_3$ gives *N-chloromethylbenzoylamino succinimide*, m. 155–7°, sol., on boiling, in 15

parts EtOH, 25 parts CHCl_3 and 110 parts Et₂O, insol in C_6H_6 . *Acetylaspargine*, distd. *in vacuo* (H_2O pump) to a temp. of 200° , gives AcNH_2 . At 280° , a yellow oil distills, solidifying to crystals (19.5% yield) of *acetylaminosuccinimide*, m. $170-1^\circ$, sol. in 7 parts H_2O or 15 parts EtOH. Formylaspargine (V) prepd. from asparagine and HCO_2H , m. $168-9^\circ$ (decompn.), sol. in 3 parts H_2O , or 5 parts EtOH. Heating of V gave a distillate of HCO_2NH_2 . Distn. of the K salt of I gave BzNH_2 , b₁₃ 210° , m. $126-8^\circ$, in 55% yield.

M. A. YOUTZ

d-Glutamic acid. H. B. LEWIS, H. M. CHILES AND G. J. COX. *Organic Syntheses* V, 63-7(1925).—Directions are given for the hydrolysis of gluten from wheat flour, and the isolation of 74-82% *d*-glutamic acid.

C. J. WEST

Rotatory dispersion of derivatives of tartaric acid. II. Acetyl derivatives. P. C. AUSTIN AND J. R. PARK. *J. Chem. Soc.* 127, 1926-34(1925); cf. *C. A.* 19, 249. If special care is taken to eliminate moisture solus. of diacetyltartaric anhydride in Me_2CO or AcOEt do not exhibit mutarotation and the strong *d*-rotations are permanent. The rotations conform to the requirements of "simple" rotatory dispersion. On adding H_2O to the dry solus. a change of rotation soon became apparent, the rate of change increasing with the amt. of H_2O present. With 1 and with 4 mols. of H_2O , final steady values were reached after about 1.5 days and 16 days, resp. That this mutarotation is due to the hydrolysis of the anhydride ring is shown by the isolation of pure diacetyltartaric acid from solns. in which mutarotation was complete. The final readings were strongly *l*-rotatory but the values depended on the amt. of H_2O used. The pure acid, m. 118° , is strongly *l*-rotatory in dry Me_2CO and its rotatory dispersion is also simple. Its mol. rotatory power is identical with that calcd. from the final readings after mutarotation, when 1 mol. of H_2O is used. This indicates that the ale. HO groups are important, though possibly not essential factors, in the development of anomalous rotatory dispersion in tartaric acid. In the mutarotation of the anhydride there is a development of anomalous rotatory dispersion during the transition from the simple dispersion of the *d*-rotatory anhydride to the simple dispersion of the *l*-rotatory acid. A change of a very similar character was observed when a soln. of the anhydride in warm H_2O was cooled to 20° . Values are given for numerous wave lengths for the anhydride in Me_2CO at 20° , in AcOEt at 20° , in wet Me_2CO at 20° , the acid in H_2O at 20° and in Me_2CO at 20° .

C. J. WEST

Ethyl oximalonate. A. W. DOX. *Organic Syntheses* IV, 27-8(1925).— Na_2O_3 , passed into $\text{CH}_2(\text{CO}_2\text{Et})_2$ at 0° , gives 74-6% $\text{CO}(\text{CO}_2\text{Et})_2$.

C. J. WEST

Acetonedicarboxylic acid. ROGER ADAMS, H. M. CHILES AND C. F. RASSWEILER. *Organic Syntheses* V, 5-7(1925).—Citric acid, added to fuming H_2SO_4 (20% SO_3) at -5° , gives 92-7% $\text{CO}(\text{CH}_3\text{CO}_2\text{H})_2$.

C. J. WEST

Ethyl acetonedicarboxylate. ROGER ADAMS AND H. M. CHILES. *Organic Syntheses* V, 53-4(1925).— $\text{CO}(\text{CH}_2\text{CO}_2\text{H})_2$ and EtOH-HCl give 42-6% of $\text{CO}(\text{CH}_2\text{CO}_2\text{Et})_2$.

C. J. WEST

Tricarballic acid. H. T. CLARKE AND T. F. MURRAY. *Organic Syntheses* IV, 77-9(1925).— $(\text{EtO}_2\text{C})_2\text{CHCH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$, heated with equal vols. of HCl and H_2O until evolution of CO_2 ceases, gives 95-6% of $\text{HO}_2\text{CCH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CO}_2\text{H}$.

C. J. WEST

α,γ -Dichloroacetone. J. B. CONANT AND O. R. QUAYLE. *Organic Syntheses* II, 13-5(1922).— $(\text{ClCH}_2)_2\text{CO}$ is obtained in 65-70% yields from $(\text{ClCH}_2)_2\text{CHOH}$, $\text{Na}_2\text{Cr}_2\text{O}_7$, and H_2SO_4 .

C. J. WEST

Reduction of symmetrical dichloroacetone by yeast. HEMENDRA KUMAR SEN AND CHITITARANJAN BARAT. *Quart. J. Indian Chem. Soc.* 2, 77-81(1925); cf. *C. A.* 19, 816.—Reduction of 9 g. $\text{CO}(\text{CH}_2\text{Cl})_2$ by yeast in the presence of sugar gave 4.8 g. $\text{HOCH}(\text{CH}_2\text{Cl})_2$, b. 178° ; its *allophanic ester*, m. 182° , results by the use of an excess of NH_2COCl .

C. J. WEST

Ethyl propane-1,1,2,3,-tetracarboxylate. H. T. CLARKE AND T. F. MURRAY. *Organic Syntheses* IV, 29-30(1925).— $\text{CH}_2(\text{CO}_2\text{Et})_2$, $(:\text{CHCO}_2\text{Et})_2$ and EtONa give 95-6% of $(\text{EtO}_2\text{C})_2\text{CHCH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$.

C. J. WEST

Preparation of thiocyanogen from thiocyanic acid. H. P. KAUFMANN AND F. KÖGLER. *Ber.* 58B, 1553-6(1925).—Solns. of HSCN in org. solvents were prepd. by covering solid NaSCN with the solvent (CCl_4 , CS_2 , CHCl_3 , Et_2O), dropping in 50% H_2SO_4 with vigorous stirring and drying carefully over P_2O_5 . At higher concns (e. g. 20%) such solns. are stable only in a freezing mixt. In the present work approx. $N/3$ solns. were used. Such solns. were shaken with dry MnO_2 or PbO_2 , care being taken that the HSCN should be present in excess. There was a slight evolution of heat and samples of the filtered liquid were examd. at definite time intervals. It contained no Mn or Pb, liberated I from aq. alkali iodides (unless previously shaken with H_2O ; the aq. ext.

contained H_2SO_4 and HCN), converted white CuSCN into black $\text{Cu}(\text{SCN})_2$, and polymerized on standing or gentle warming, becoming yellow and depositing yellow flocks. These reactions indicate the presence of free $(\text{SCN})_2$, the amt. of which, however, as detd. by titration of the amt. of I liberated from iodides and comparison with the titer of the original HSCN soln., was at best but a few % of that calcd. from the equation $2\text{HSCN} + \text{O} = (\text{SCN})_2 + \text{H}_2\text{O}$, due allowance being made for the hydrolysis of part of the $(\text{SCN})_2$ by the H_2O produced in its formation. On the other hand, when $\text{Pb}(\text{OAc})_4$ in AcOH or CHCl_3 is treated with somewhat more than the calcd. amt. of HSCN soln., $\text{Pb}(\text{SCN})_2$ is at once pptd. and the Pb-free filtrate contains free $(\text{SCN})_2$ in almost theoretical amt.; with $1\text{-C}_{10}\text{H}_7\text{OH}$ it gives $1,4\text{-C}_{10}\text{H}_6(\text{OH})\text{SCN}$, m. 113° (given by mistake as 87° in C. A. 17, 3480). C. A. R.

Cheno-desoxycholic acid (II) (WINDAUS, SCHOOR) 11A. Reactions of *p*-phenylenediamine with CH_2O and H_2O_2 (LÄTT) 11A.

Benzoic acid. A. GEORGE. U. S. 1,557,153, Oct. 13. PhCCl_3 is hydrolyzed directly with H_2O in the presence of an anhydrous metal compd (such as ZnCl_2 on pumice) at a temp. of $100\text{--}120^\circ$, while agitating the reaction mixt. and adding the H_2O at substantially the rate at which it reacts.

Benzoic acid. H. W. DAUBT. U. S. 1,551,373, Aug. 25. A soln. of phthalic acid or a phthalate is heated to $150\text{--}300^\circ$ to form benzoic acid. The heating may cover a period of 20 hrs.

Benzoyl chloride. A. GEORGE. U. S. 1,557,154, Oct. 13. H_2O is gradually added to an agitated mixt. of PhCCl_3 contg. a catalyst such as ZnCl_2 or other Zn compd in suspension and maintained at a temp. (which may be about $100\text{--}120^\circ$) at which active hydrolysis takes place. Not more than 10 in excess of the theoretically required H_2O (to form benzoyl chloride) is used.

Alkyl chlorides. W. R. WEBB. U. S. 1,560,625, Nov. 10. An olefin, e. g., C_2H_4 , from which $\text{C}_2\text{H}_5\text{Cl}$ is to be produced, is treated with anhyd. HCl in the presence of AlCl_3 and the alkyl chloride is distd. and purified.

Diacetone alcohol. W. J. EDMONDS. U. S. 1,550,792, Aug. 25. Acetone is agitated in the presence of $\text{Ca}(\text{OH})_2$ or other finely divided alk. earth hydroxide, in order to cause the formation of diacetone alc.

Catalytic oxidation of toluene or other aromatic compounds. J. V. MEIGS. U. S. 1,560,297, Nov. 3. The vapor of toluene or other substance to be oxidized is mixed with air or other O-contg. gas and with a gaseous cooling agent such as steam and subjected, at a temp. between 200° and redness, to the action of a vesiculated catalyst which may comprise Fe vanado chromate or a similar compd. and Ag. The process is regulated so that the CO_2 in the exit gases is maintained at 3% or less.

Urea from ammonium carbamate. N. W. KRASE and V. L. GADDY. U. S. 1,558,185, Oct. 20. A mixt. of ammonium carbamate and carbonate is compressed and charged into a heated autoclave.

A—GENERAL

FRANK P. UNDERHILL

Lucius L. Van Slyke. R. W. THATCHER. *Ind. Eng. Chem.* 17, 1204(1925).—A brief biography, with portrait. E. J. C.

The fermentive decomposition of nucleic acid. L. ROSENFELD. *Chem. Zelle u. Gewebe* 12, 101–14(1925).—An investigation on the effect of exts. of the thymus, liver, spleen, kidney and pancreas both with and without insulin on the decompn. (as judged by the free H_3PO_4 produced) of the Na salt of thymus nucleic acid, of hexosephosphoric acid and of sucrosephosphoric acid. The largest degree of hydrolysis was caused by exts. of the pancreas and kidney. In each case the addn. of insulin resulted in the production of 10 to 20% increase in free H_3PO_4 . Control expts. in which boiled organ ext. was used showed no hydrolysis. H. J. DEUEL, JR.

The chemical mechanism of fat formation from sugar. H. HAEHN and W. KINTOP. *Chem. Zelle u. Gewebe* 12, 115–56(1925).—A study of the synthesis of fat from sugar and from supposedly intermediary products in the glucose fat transformation by

the yeast fungus *Endomyces vernalis*. Yeast cells after a short preliminary period of growth in the usual nutrient medium were placed in phosphate-buffered solns. ($p_H = 6.8$) of the substance under investigation and the fat formation was followed by microscopic examn. of the cells. Fat formation took place if the cells were suspended in glucose or in 1 to 4% concns. of pyruvic acid, glycerol, lactic acid, acetaldehyde or aldol. This was manifest by the appearance of many small fat droplets in the cell, which increased in size from day to day and ultimately filled $\frac{2}{3}$ to $\frac{3}{4}$ of the cell. These results support the theory that acetaldehyde is one of the intermediate substances in the formation of fat from carbohydrate but they do not indicate whether the decompn. of glucose proceeds *via* lactic or pyruvic acid. Glycerol is assumed to yield first methylglyoxal and then either lactic acid or pyruvic acid from which acetaldehyde is formed by virtue of which fat may be synthesized. H. J. DEUEL, JR.

The chemistry of the cell nucleus and some nucleic acid protein compounds. JOSEF SCHUMACHER. *Chem. Zelle u. Gewebe* **12**, 175-93(1925). H. J. DEUEL, JR.

• **Takadiastase.** • S. NISHIMURA. *Chem. Zelle u. Gewebe* **12**, 202-16(1925).—In takadiastase were found amylase, invertase, maltase, proteases, catalase, lipase, pepsin, lactase, inulase, sulfatase and amidase. These enzymes can be quant. removed with fuller's earth, from which they may be freed by washing with weakly alk. phosphate soln ($p_H = 8.0$). An increased activity of all the enzymes results, the increase (approx. 3 times) being the same within the limits of exptl. error for all the enzymes. The increased activity of the enzymes is explained as due to their removal from an inhibitory substance in the original soln. On a second purification with fuller's earth, there is only a slight increase in the activity of invertase, maltase and protease, while a very large increase in the activity of the catalase and amylase was noted. H. J. D., JR.

The function of insulin, of vitamins and of hormones from a catalytic standpoint. N. R. DIAR. *Chem. Zelle u. Gewebe* **12**, 217-25(1925).—Insulin plays the role as an accelerator of the oxidation of glucose by the air in the presence of enzymes. Since diabetes is traced back to a deficient oxidation of glucose in the blood and tissues, it is recommended to administer preps. of iron salts, colloidal iron, or $Fe(OH)_3$, in the treatment of diabetes. Vitamin A is assumed to be a catalyst aiding in the oxidation of fats, and vitamins B and possibly C are supposed to aid in the oxidation of carbohydrate. Therefore the latter are also recommended in the treatment of diabetes. Hormones are assumed to be general catalysts. H. J. DEUEL, JR.

The osmotic pressure of hemoglobin in the absence of salts. G. S. ADAIR. *Proc. Roy. Soc. (London)* **109A**, 292-300(1925); cf. *C. A.* **18**, 2005—Osmotic pressure detns. for dialyzed Hb made by previous workers varied from 3.5 mm. to 12.1 mm. for a 1% Hb soln. Variations were probably due to impurities of acids or bases. The higher values have been accepted as correct since they agree with the molecular weight of 16,700 as detd. by the analysis for Fe while the lower values have been attributed to aggregations of the mols. caused by the salts. Repetition of the work with isoelec. Hb solns. gave pressures of 3.2 mm. or less and pressures of 10 mm. were only obtained when cond. measurements or detns. of H-ion concn. showed the presence of acid or base. Therefore the mol. wt. of Hb is about four times that of the equiv. wt. (16,700). H. J. DEUEL, JR.

The peptidase economy of man and of our experimental animals. H. PREIFFER AND F. STANDENATH. *Fermentforschung* **8**, 327-58(1925).—For detns. of peptidase in urine and serum the cleavage of glycyltryptophan was estimated by comparing the intensity of the red color obtained from the liberated tryptophan by addn. of Ca hypochlorite. A study was made of the influence of age on the urinary excretion of enzyme. The 1st urine of the new born child was found to contain demonstrable amts. of peptidase. In the 1st few weeks and months after birth the peptolytic index rises to unusually high values, then toward the end of the 1st yr. it diminishes and frequently disappears, as is the case also in the later years of childhood. No definite conclusions can yet be reported regarding the influence of puberty. The urine of males between the ages of 20 and 30 shows as a rule a high peptolytic index. This is attributed in part to undernourishment of the subjects, but is believed to be independent of the moderate use of alc. beverages. Differences due to sex have not been established because of other complicating factors. The urine of healthy, well-nourished subjects of regular habits and of ages between 30 and 50 then shows little or no peptidase activity, as in the later years of childhood. Where peptidase is excreted in demonstrable quantities, the greatest amt. is usually observed in the morning urine. This is probably associated with fullness of the lower bowel. In constipated subjects the urinary peptidase can even be made to disappear by thorough evacuation of the bowel. It may be assumed that congenital as well as acquired variations in permeability of the intestinal wall are an

important factor in detg. the amt. of peptidase excreted in the urine. A 2nd source of the urinary enzyme may be the tissue peptidase liberated with the death of the body cells. Attempts to distinguish between intestinal and cell enzyme by means of adsorption, stability and optimum conditions of activity have not been successful. Rabbits and guinea pigs do not excrete peptidase in the urine, but the enzyme may be demonstrated in the blood serum. A. W. DOX

The reactions of *p*-phenylenediamine with formaldehyde and hydrogen peroxide. A comparison with the reactions of natural peroxidases. BERTHA LATT. *Fermentforschung* 8, 359-422(1925).—The oxidation of *p*-C₆H₄(NH₂)₂ by H₂O₂ is greatly accelerated by the presence of raw milk, soln. of blood pigment, or very dil. CH₂O soln. While the pigment formed through the action of the blood peroxidase seps. rapidly in cryst. form, that obtained by the action of CH₂O remains finely dispersed and does not flocculate out unless an electrolyte is added. The final product is, however, identical in both cases. The color obtained in the presence of milk peroxidase is somewhat different, but the variation is probably due to other constituents of the milk, since the same color is obtained with boiled milk in the presence of CH₂O. The isomeric *o*- and *m*-diamines are less sensitive as peroxidase reagents. The shade and intensity of the color in the case of all 3 activators is altered by the presence of various phenols. Acids tend to displace the color somewhat toward the red, while bases are distinctly inhibitory. The effect of salts is proportional to their concn and consists in the development of turbidity and a displacement of the color. Org. solvents such as Et₂O, CHCl₃, and paraldehyde are without influence. EtOH in 10% concn is inhibitory, while urethan accelerates the oxidation. Colloids (casein, albumin, protein, peptone, starch, etc.) in general produce a turbidity but otherwise their effect varies according to the presence of H- or OH ions. The peroxidase action of CH₂O is shown to a less extent by AcH, while the higher homologs are inactive. The oxidation product of the *p*-C₆H₄(NH₂)₂-CH₂O-H₂O₂ system was isolated and showed a m. p. of 242-3°; hence, it was obtained in a purer form than by Bandrowski, who reported a m. p. of 230-1°. The indophenol obtained as an oxidation product in the system *p*-C₆H₄(NH₂)₂-*o*-MeC₆H₄OH-CH₂O-H₂O₂ was also isolated and gave a m. p. of 155°. A. W. DOX

Studies on the formation of pigments. III. Fermentative micro-detection of 3,4-dihydroxyphenyl- α -aminopropionic acid along with tyrosine. HANS SCHIMALFUSS AND HANS WERNER. *Fermentforschung* 8, 423-7(1925).—By means of test papers prepd. from the hemolymph of *Archia caju* comparative studies were made of the rate and intensity of pigment formation from 3,4-dihydroxyphenyl- α -aminopropionic acid (I) and tyrosine. At a diln. of 0.014 mg. per cc I can be detected in the presence of 28 times this amt. (cold satd. soln.) of tyrosine, the latter alone giving no color in 20 hrs. Most of the pigment develops in a comparatively short time, the rate and intensity of the reaction being proportional to the concn. of enzyme and chromogen. Adrenaline-HCl reacts only in very dil. soln. because of the destructive action of the acid component on the enzyme. A. W. DOX

Malt amylase. I. Determination of dextrinizing and saccharifying action of amylase. II. Influence of various experimental conditions on amylase action. TU. SABALITSCHKA AND C. SCHULZE. *Fermentforschung* 8, 428-48(1925).—Comparative studies of the dextrinizing and saccharifying power of amylase preps. under various conditions were made on aliquots of the digestion mixt. Saccharifying power was detd. by treatment with 0.1 N NaOH and I, the oxidation being allowed to proceed 20 min. and the excess I then titrated with 0.1 N Na₂S₂O₄. Dextrinizing power was detd. by treatment with I in KI soln. and comparing the resulting color with a color scale prepd. by mixing solns. of Prussian blue, carmine, Na nitroprusside, CoSO₄ and K₂CrO₄ in varying proportions. No difference was found between the action of filtered and unfiltered amylase soln. After standing 24 hrs. a very slight acceleration of dextrinizing action was observed. The optimum starch concn. for detus. by the method employed was 0.5%, since a lower concn. results in achromic products and a higher concn. leaves unchanged starch, which interferes with the color comparisons. For the same reason, the optimum concn. of enzyme prepn. was found to be 0.2%. III. Influence of adsorbents on the dextrinizing and saccharifying action of amylase. *Ibid* 149-63. Treatment of amylase soln. with various adsorbents, viz., linden charcoal, kieselguhr, animal charcoal, sponge charcoal, alumina and kaolin, showed no difference in effect on the dextrinizing and saccharifying action. Regardless of the amt. of enzyme removed by adsorption, the 2 curves ran parallel in every case. The evidence supports the view that dextrinizing and saccharifying action are not functions of 2 sep. enzymes. IV. Influence of caffeine and aldehydes on the dextrinizing and saccharifying action of amylase. *Ibid* 464-73.—Neither 0.3% caffeine nor 0.06% sulfonal has any influence

on amylolytic activity. CH_2O at 0.0006–0.006% accelerates the action, at 0.02% it shows no effect; at 0.06% it is strongly inhibitory. AcH and EtCHO are without effect at low concns. and inhibitory at higher concns. Notwithstanding these variations in effect upon amylase, the curves for dextrinizing action and saccharifying action ran parallel in every case.

A. W. Dox

Some scleroproteins. ZDENKO STARY AND INGOMAR ANDRATSCHKE. *Z. physiol. Chem.* **148**, 83–98(1925).—With respect to N distribution, individual scleroproteins differ more from each other than they do from ordinary proteins. The peculiar properties they have in common are probably due to other characteristics such as anhydride linkages. Detn. of N in the various fractions in 6 scleroproteins gave the following results:

	NH_2N	Humic N	Diamino an- cystine N	Mono. N
Human hair	7.93	2.02	28.14	61.9
Gorgonin	3.36	1.11	22.76	72.78
Spongin	6.24	1.49	14.73	77.54
Conchiolin	4.17	6.16	19.33	70.34
Bysus	5.55	4.51	16.02	73.91
Ovokeratin	3.51	2.73	20.91	72.85

The two-phase action of hormones. The antagonistic actions of internal secretions. H. ZONDEK AND H. UCKO. *Z. physiol. Chem.* **148**, 111–23(1925); cf. *C. A.* **19**, 1868. Not only is the action of hormones increased or decreased by the addn. of electrolytes, such as salts of Ca, K, Mg, or by a change in the H^+ -ion concn., but under certain conditions the direction of activity is reversed. Certain hormones are known to be mutually antagonistic, e. g., thyroid and thymus, thyroid and pancreas, pancreas and suprarenals. It is now shown that one and the same hormone may function in opposite directions. The 2nd phase, which appears to be a reversal of the primary action, had already been observed in the case of adrenaline, pituitrin and insulin, but was regarded as a "reaction" due to a protective device of the living cell which tended to compensate the shock resulting from the poison administered. A study of the effect of insulin on the blood sugar picture of rabbits shows that the administration of min quantities of the hormone such as would function in the normal physiol. process demonstrates clearly the 2nd phase where a rise in blood sugar occurs. For the purpose of maintaining physiol. equil. as regards blood sugar, metabolism, etc., the 2nd phase of the hormone action is as necessary as the 1st phase. Moreover, the injection of a combination of hormone with CaCl_2 or MgCl_2 results frequently in an immediate rise in blood sugar above the normal, whereas the CaCl_2 alone is without effect. The 2-phase antagonism is not peculiar to the hormone itself, but is detd. rather by changes in the cell medium. Cf. Karger (*C. A.* **19**, 2527).

A. W. Dox

The bile acids. XIV. MARTIN SCHENCK. *Z. physiol. Chem.* **148**, 218–24(1925); cf. *C. A.* **19**, 2675.—From sheep bile, after sapon., treatment with various solvents and sepn. of the Ba salts, 4% of cholic acid and 0.4% of chenodeoxycholic acid were obtained. The amts. correspond to those previously obtained from goat bile.

A. W. Dox

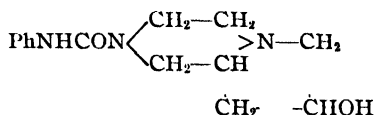

Cheno-desoxycholic acid. II. A. WINDAUS AND A. VAN SCHOOR. *Z. physiol. Chem.* **148**, 225–31(1925).—Desoxycholic acid from beef bile and cheno-desoxycholic acid (I) from goose bile are isomers differing merely in the location of the 2 secondary OH groups. These groups represent the point of attack when the cyclic nuclei are ruptured by oxidizing agents, and from the character of the oxidation products the location of the OH may be detd. The probable formulas are:

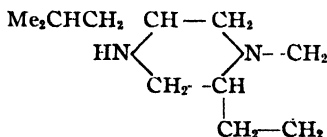

Oxidation of I with NaOBr gives *cheno-desoxybilibanonic acid*, m. 253° in 30% yield. This represents a rupture at the same point as in the oxidation of cholic acid to bilibanic acid. *Me ester*, m. 107°, was prepd. by esterification with CH_2N_2 . The location of the other OH is shown by the oxidation of cheno-dehydrodesoxycholic acid (II) to cheno-desoxybilibanonic acid (III), an isomer of desoxybilibanonic acid and of isodesoxybilibanonic acid; hydrogenation of III then gives lithobilibanonic acid, the constitution of which is known. By treatment of II in AcOH with HNO_3 nitration occurs with formation of a *dinitroketotricarboxylic acid*, $\text{C}_{24}\text{H}_{34}\text{N}_2\text{O}_{11}$, m. 222°. *Tri-Me ester* m. 156°. A. W. D.

Iron studies. I. The action of digestive enzymes on the hemoglobin iron. GEORGE BARKAN. *Z. physiol. Chem.* **148**, 124-54 (1925).—Detns. by the thiocyanate method in the ultra-filtrate showed that 0.4% HCl liberates a small amt. of Fe from blood but this is not due to a cleavage of hemoglobin. The liberation occurs immediately and does not increase when the action of the acid is prolonged. The amt. is equiv. to $1/18-1/20$ of the hemoglobin Fe. Salts of both Fe^{++} and Fe^{+++} added to the blood are recovered quant. in the case of pepsin digestion but only 68-78% in the case of trypsin digestion. Neither pepsin nor trypsin alone nor the 2 in combination causes any perceptible cleavage of Fe from hemoglobin. A. W. DOX

Further studies on the structure of proteins. Anhydride formation from di- and tripeptides. Reduction of gelatin. EMIL ABDERHALDEN AND ERNST SCHWAB. *Z. physiol. Chem.* **148**, 254-63 (1925).—The difference in stability of various proteins toward digestive enzymes appears to depend upon the presence or absence of diketopiperazine rings. The proteinoids contain such groupings, while the proteins which are directly concerned in cell metabolism represent more labile structures. Stability may depend further upon the nature of the amino acids which comprise the diketopiperazine ring, or on the substituent groups present. In a study of the secondary formation of diketopiperazines from dipeptides by heating in glycerol it was found that the yields vary considerably with different peptides. Leucylglycine gives a much better yield of the anhydride than does glycyltyrosine. *Leucyl (glycylleucine anhydride)*, m. 263° (decompn.), obtained by heating leucylglycylleucine in glycerol 8 hrs. at 180-90°, represents a diketopiperazine with an amino acid substitution. A further insight into the structure of the protein mol. may be obtained by reduction without preliminary hydrolysis. Finely powdered gelatin was treated with Na and EtOH, whereupon considerable NH_3 was evolved. The product was neutralized, evapd. to remove EtOH, made alk. with NaOH and extd. with CHCl_3 and Et_2O . By treatment of the ext. with PhNCO a cryst. substance was obtained which represents a condensation product of glycine, hydroxyproline and PhNCO . It decomp. 198° and the structure is believed to be

After hydrolysis by means of HCl to remove PhNH_2 and CO_2 , the piperazine-HCl was obtained in crystals decomposing 190°. From this the Me ether, m. 195°, was prepd. by treatment with CH_2N_2 . In the same manner a 2nd piperazine was obtained from the mother liquor. It is comprised of leucine and proline, m. 181°, and corresponds to the formula:

A. W. DOX

Arginase. II. The determination of arginase in animal organs. S. EDLBACHER AND H. RÖTHLER. *Z. physiol. Chem.* **148**, 264-72 (1925); cf. C. A. 19, 2675.—The arginase unit selected represents the amt. of arginase which liberates from 10 cc. of a 1% soln. of arginine carbonate at p_{H} 9.5 (glycine-NaOH-NaCl buffer) in 60 min. at 38° an amt. of urea which forms 0.34 mg. NH_3 when treated with urease and detd. by the Folin acration method. The glycerol exts. of liver, testes and other organs gave arginase curves of uniform character, the exception being the arginase of the kidneys of birds where the curve assumes a somewhat different form, the extent of cleavage here being proportional to the amt. of enzyme. This anomaly is attributed to the presence of

inhibitory substances. The most accurate detns. are obtained with solns. contg. 4-30 arginase units, and for higher values corresponding dilns. should be made. **III. Arginine metabolism and sexuality.** *Ibid* 273-82.—Both with birds and mammals the arginase content per g. of organ (liver, testis, kidney) is greater in the male than in the female. For domestic fowl the av. values are: male 0.336, female 0.227 units. The enzyme is therefore closely related to reproductive function. In mammals the arginase content of the testes is much greater after than before puberty. In general the arginase values for the female are 60-70% those of the male, in spite of the large differences in abs. values between mammals and birds. The high values for the avian kidney indicate that this organ functions not merely as an excretory organ but has to do also with the sex function of birds. Spleen, thyroid, pancreas, intestinal mucosa, muscle and heart were in all cases negative, while placenta and thymus contained small amts. of arginase. Enzymic cleavage is, however, only 1 possibility in the process of intermediary arginine metabolism; it is probable that oxidative conversion into creatine occurs, especially before puberty or after castration. A. W. Döx.

Bacterial arginase. A. KOSSEL AND F. CURTIUS. *Z. physiol. Chem.* **148**, 282-9 (1925).—By means of flavianic acid (1-naphthol-2,4-dinitro-7-sulfonic acid) the residual arginine from enzyme expts. may be pptd. quant., then converted into the sulfate and examd. polarimetrically. In expts. where the source of arginase was an emulsion of *pyocyanus* approx. 50% of the arginine was thus recovered and showed *l*-rotation. The enzymic cleavage of *dl*-arginine is therefore asymmetrical, contrary to the statement of Hino (*C. A.* **18**, 2538). Not all strains of *pyocyanus* contain arginase, and the presence of the enzyme in a given strain is variable. Addn. of boiled ext. of liver produces no activation. Living cultures, even though arginase-free, break down *dl*-arginine completely, probably by oxidation. A. W. Döx.

The natural synthesis of amino acids and its experimental reproduction. F. KNOOP AND HUBT OESTERLIN. *Z. physiol. Chem.* **148**, 294-315 (1925).—The possibility has been previously suggested that the biol. synthesis of amino acids may involve the hydrogenation of unstable hypothetical imino acids which might be regarded as intermediate stages in both synthesis and degradation and therefore give the reaction a reversible character. Such imino acids, or hydroxyamino acids, have not been isolated, presumably because of their instability, but a system contg. a mixt. of α -keto acid and NH_3 should answer the same purpose for catalytic hydrogenation studies. It was found that α -amino acids can actually be synthesized in good yields by this procedure. α -Ketobutyric acid and NH_3 in EtOH or H_2O when hydrogenated in the presence of Pd black gave 58% of α -aminobutyric acid; with MeNH_2 in place of NH_3 the product was 62% of methylaminobutyric acid. Other examples described are: trimethylpyruvic acid \rightarrow pseudoleucine; oxalacetic \rightarrow aspartic acid (26%); α -ketoglutaric \rightarrow glutamic acid (23%); levulinic \rightarrow α -aminovaleric acid (30%), phenylglyoxylic \rightarrow phenylaminoacetic (60%); phenylpyruvic \rightarrow phenylalanine (62%); phenylketobutyric \rightarrow phenylaminobutyric (65%), benzoylacetic \rightarrow phenyl- β -alanine (30%). Since only NH_3 and MeNH_2 , but not Me_2NH , allow the org. fixation of N in this manner, the mixt. reacts presumably as an imino acid, and the H is added at the double bond β - and γ -keto acids give much less amino acid or none at all. In many cases where the formation of amino acid encounters difficulties the hydroxy acid is formed instead. Such a reduction to the alcohol stage, which is a frequent occurrence in the animal organism and in bacteria, occurs less readily in the above procedure. The ease of reaction between NH_3 and α -keto acids makes it appear probable that this is the natural mode of amino acid formation. It explains also the necessity of urea formation in the animal body. Even though the amino acid synthesis plays only a minor role, the reaction is reversible and the NH_4 ions must be removed before the utilization of protein fragments can proceed. This is accomplished by conversion into urea. A. W. Döx.

Transformation products of the pigments from flesh and blood. VI. A transformation product ("copratin") originating from α -hematin by intestinal putrefaction and the related porphyrin; copratin and the pyridine blood test. O. SCHUMM. *Z. physiol. Chem.* **149**, 1-18 (1925); cf. *C. A.* **19**, 3493.—Spectroscopic examn. of feces, obtained from normal individuals on a mixed diet and from patients with bleeding in the region of the digestive tract, and treated with pyridine and $(\text{NH}_4)_2\text{S}$ or N_2H_4 , H_2O shows the presence of a new pigment differing from the so-called pyridine-hemochromogen. The pigment, for which the name *copratin* is proposed, does not result from the action of pyridine on blood or hematin, but from intestinal putrefaction of α -hematin. It is characterized not only by the pyridine reaction but also by its conversion into a new porphyrin, *copratoporphyrin*, when treated with N_2H_4 , H_2O -AcOH. This differs strikingly from the α -hematoporphyrin obtained from hematin by the same treat-

ment. The porphyrin of coproatin when boiled with $\text{Fe}(\text{OAc})_2$ in AcOH forms an Fe deriv. which shows the same peculiar pyridine reaction as the original coproatin. In this manner the striking difference between coproatin and hematin has been established. The enterogenous origin of coproatin from α -hematin is shown by its presence in the feces of healthy persons on a diet contg. blood or hematin and of patients suffering from stomach bleeding (ulcer, carcinoma). The relative proportions of hematin and coproatin are variable. Bacterial fermentation outside of the human body also gives rise to a pigment probably identical with coproatin. A. W. DOX

The bile pigments. XVII. Copper bilirubin. WM. KÜTSEER. *Z. physiol. Chem.* **149**, 30-43(1925); cf. *C. A.* **19**, 1705.—A Cu complex of bilirubin is easily obtained by treating bilirubin soln. in NH_4OH with CuSO_4 , shaking the mixt. 15-20 min. until the color becomes emerald green, then pptg. the Cu complex by addn. of AcOH . The complex exists in 2 modifications, an amorphous form which can be crystd. from EtOBz and a cryst. form obtained from pyridine soln. It is very stable; it does not oxidize in alk. soln., does not add CH_3N , and is not decompd. by acids. Esterification gives a di-Me ester which forms a tri-HCl salt. By the introduction of Cu the "sensitive" place of the bilirubin mol. is protected and the stability of the mol. greatly increased. An OH remains which can be methylated or benzoylated. Reduction with Na amalgam results in the formation of mesobilirubinogen. Treatment with Zn dust and AcOH probably ruptures a pyrrole ring with liberation of NH_3 . An Fe complex was also prepd. by treating bilirubin with $\text{Fe}(\text{NH}_4\text{SO}_4)_2$ and NH_4OH and pptg. with AcOH . A. W. DOX

The reductase (dehydrogenase) of yeasts. I. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* **149**, 44-51(1925).—The crude co-enzyme ext. from yeast contains a co reductase which activates the decolorization of methylene blue. It is not identical with co-enzyme. It is more easily washed out from bottom yeast H than from top yeast R. The co reductase from dried yeast (MeAc yeast) activates the methylene blue reduction of washed muscle and may therefore be identical with the co-reductase of muscle. A. W. DOX

Inhibition substance of fermentation. KARL MYRBACK. *Z. physiol. Chem.* **149**, 52-9(1925).—A cold H_2O ext. of veal contains a substance which inhibits yeast fermentation. This inhibition substance is adsorbed by kaolin and by $\text{Al}(\text{OH})_3$, and a complete elution may then be effected by 3% phosphate soln. (p_{H} 6.2) but not by H_2O . The substance is destroyed by boiling and is not diffusible through collodion. Elution from the $\text{Al}(\text{OH})_3$ sorbate gives a product 10 times as pure as the original ext. Bottom yeasts are strongly inactivated while top yeasts are not inactivated but even show a slight activation, probably due to the presence of co-enzyme and zymophosphate in the muscle ext. In their behavior toward the inhibition substance bottom yeasts and top yeasts thus show a striking difference. A. W. DOX

The natural porphyrins. XVII. A new conversion of uro- into coproporphyrin and some derivatives of these porphyrins. HANS FISCHER AND JOSEF HILGER. *Z. physiol. Chem.* **149**, 65-70(1925); cf. *C. A.* **19**, 2676.—Assuming that the carboxyls in uroporphyrin are present as malonic acid groupings, it should be possible to convert uro- into coproporphyrin by the expulsion of CO_2 by heat. This reaction was found to occur at 180° with evolution of CO_2 corresponding to 4 CO_2H groups, and in the residue coproporphyrin was identified by means of its Me ester. Fuming HNO_3 converts uroporphyrin Me ester into a new porphyrin, m. 256° , which is not identical with coproporphyrin Me ester since the mixed m. p. shows a depression of 40° . The substance forms a cryst. Cu salt m. $286-7^\circ$ (decompn.). The coproporphyrin Me ester when treated with HNO_3 in the same manner forms a dinitro ester, m. 182° . Complex Cd and Mn salts were obtained from the copro-ester, but Ni_2OH was without action. A. W. DOX

Studies on desmotropic forms of diketopiperazines. EMIL ABERHALDEN AND ERNST SCHWARZ. *Z. physiol. Chem.* **149**, 100-2(1925).—After heating a mixt. of glycine anhydride, tyrosine and glycerol in an oil bath 5 hrs. at $190-200^\circ$ and extg. the condensation product with CHCl_3 , a residue remains which crystallizes from EtOH and decomp. 282° . The analysis corresponds to that of glycine anhydride. The substance is believed to be the tautomeric form of glycine anhydride, $\text{HNCH}=\text{C}(\text{OH})\text{NHCH}=\text{C}(\text{OH})$. Unlike ordinary glycine anhydride it reacts with

CH_3N_2 to form a methyl ether, m. below 100° . Heating of glycine anhydride alone with glycerol gave the same product but in smaller yield. A. W. DOX

The importance of the lipoids and their relation to cell equilibrium. M. RUBNER. *Klin. Wochschr.* **4**, 1849-53(1925).—A bibliographical review. MILTON HANKE

Autolysis of the thyroid gland. V. FERRERO. *Arch. sci. med.* **47**, 294-301 (1925).—In small pieces of the canine thyroid subjected to aseptic autolysis there occurs from the 4th to the 16th hr. a gradual destruction and final complete dissolution of the alveolar colloid, preceding the alterations occurring in the thyroid tissue itself. This is believed to indicate the presence in the gland of an enzyme capable of rendering the colloid sol. and hence capable of absorption during life. M. HEIDELBERGER

Cytochrome, a respiratory pigment, common to animals, yeast and higher plants. D. MELIN. *Proc. Roy. Soc. (London)* **98B**, 312-39 (1925).—Cytochrome is an intracellular respiratory catalyst which is common to animals, bacteria, yeast and higher plants. It is easily oxidized by air and reduced by the normal activity of cells or by a chem. reducing agent. In the reduced state, it has a characteristic absorption spectrum with 4 bands at approx. the same position for all species of organisms (plant or animal): 6046, 5665, 5502, 5210 A.U. the band at 6046 A.U. is composed of 3 secondary bands. In the oxidized state, definite absorption bands do not occur, merely faint shading at 520-540, 550-570. Cytochrome is present in greatest concn. in the thoracic wing muscles of flying insects, striated muscles of birds and mammals, and bakers' yeast. $\text{Na}_2\text{P}_2\text{O}_7$ and 0.0001 *N* KCN stop the oxidation of cytochrome, but do not prevent the reduction of its oxidized form by the cell; alc., HCHO, and Et urethan do not prevent the oxidation, but inhibit the reduction by the cell. Under natural conditions in the living animal, cytochrome is present in either the oxidized or the partially reduced form. The spectroscopy reveals the equilibrium between the rate of oxidation and the rate of reduction at a particular time in the animal organism. Cytochrome consists of 3 hemochromogen-compds., 2 of which contain an Fe-pyrrole nucleus; it yields 3 hemochromogens which form compds. with O_2 and CO; it is entirely distinct from muscle-hemoglobin (myochrome, myoglobin). Cytochrome and its derivs. are at least partly responsible for the peroxidase reactions of organisms. A hemochromogen-like complex (modified cytochrome) and cytochrome itself occur in the uncolored portions of plants, and yield strong KOH characteristic hemochromogens which form compds. with O_2 and CO. Cytochrome is present in aerobic bacteria. The oxyhemoglobin of muscle differs from that of blood only by a slight shift of the absorption bands toward the red end of the spectrum. JOSEPH S. HEPBURN

Experimental study on the excretory activity of the kidneys after injection of secretin from plants with remarks on the work of Halliburton and Souza on the action of spinach secretin. M. DOBREFF. *Z. ges. expil Med.* **46**, 215-23 (1925).—The intravenous or subcutaneous injection in dogs of secretin from plants (spinach, nettle) caused hyperglucemia and glucosuria with a diminished diuresis, the latter due perhaps to a lowering of blood pressure by the secretin. The method described by Halliburton and Souza (*Arch. intern. physiol.* **18**, 231-41 (1922)) for extg. plant secretin does not suffice for obtaining a good yield of active secretin. Hydrolysis with concd. HCl or H_2SO_4 , or very long extn. with boiling H_2O is necessary. HARRIET F. HOLMES

The colloidal state of protein solutions. H. R. KRUYT. *Chem. Weekblad* **22**, 473-5 (1925); cf. Kruyt and Tendeloo, *C. A.* **19**, 3192.—The views of Loeb, Hoffmann and Gortner, Pauli, and others are summarized. The minimum of the alc. no. at the isoelec. point is considered as a necessary consequence of the lower degree of hydration corresponding to the lower charge, since the two factors are interrelated. Tendeloo's results showing that the state of protein is not detd. by p_H alone stress the analogy between proteins and suspensoids against the theory of true NH_2 acid solns. In all probability protein solns. are colloidal systems governed by laws, which in other systems have been recognized as electrocapillary phenomena. MARY JACOBSEN

The chemical state of protein solutions. I. M. KOLTHOFF. *Chem. Weekblad* **22**, 489-94 (1925); cf. *C. A.* **12**, 2575; **17**, 2589; **18**, 2716, 3608.—Proteins are chem. individuals, ampholytes with individual min. equiv. wts. with respect to H^+ and OH^- , the free CO_2H and NH_2 being responsible for the acid and alkali binding capacity. The difficulties by which the adsorption theory is faced and its failure to explain the mechanism of the reactions with alkalis and acids and the influence on these reactions of polyvalent ions with opposite charge is pointed out. The chemist is concerned with the applicability of the mass action law to protein-electrolyte systems. There seems to exist a relation, although not a simple one. In studying the problem it must be borne in mind that the behavior is governed not by the concn. of H^+ or OH^- alone, but by the activity coeff. of all the ions present in the soln. The protein particle in HCl soln., e. g., carries a double layer of H^+ and Cl^- spread uniformly over the entire surface. It is important to establish the state of the double layer and the influence of the valency and the chem. nature of both the ions on the electrolyte binding capacity of the protein. MARY JACOBSEN

The presence of argon in living cells. AMÉ PICTET, WERNER SCHERRER AND LOUIS HELFER. *Helvetica Chim. Acta* **8**, 537-45(1925); cf. *C. A.* **19**, 2687.—The presence of A in yeast, beef blood clot and beef brain was established with the aid of an air-tight, air-free app. CO_2 was absorbed by KOH, O by pyrogallol; N was oxidized by elec. discharge and absorbed by KOH. Blanks without the biol. material gave no trace of A. One g. dehydrated yeast yielded on combustion 0.28-0.31 cc. A. Only about $1/8$ of this amt. was liberated in the course of glucose fermentation. The main part of O, N and A was evolved in the first $1/2$ hr. and their proportion varied during the fermentation. One g. dry blood clot evolved 0.84 cc., 1 g. dry brain 0.86 cc. A. Neither hemoglobin Merck nor fibrin de Haen yielded a trace of A. The conclusion is reached that A is enclosed in the living cells and liberated by their mechanical destruction. It is possibly the product of radioactive transformation of K. MARY JACOBSEN

The determination of amino acids formed by the hydrolysis of proteins. I. Total acids. EMILE CHERBULIEZ AND ROBERT WAHL. *Helvetica Chim. Acta* **8**, 571-82 (1925).—E. Fischer's and Dakin's methods for the isolation and identification of amino acids from protein hydrolysates are tedious and entail losses. A practically quant. method was developed which, however, gives the total amino acids only. After the removal of NH_3 , humin and diamine N in the usual way the remainder is benzoylated in NaHCO_3 soln. with a large excess of BzCl . Three benzoylations suffice to remove practically all N. The benzoylamino acids (I) are pptd. by acidulation. The NaOH -insol., ether-sol. ppt. obtained in the course of each benzoylation consists of the mixed anhydrides of benzoic and amino acids and of benzoylated phenols, carbohydrates, etc. The amino acids are easily recovered from this fraction as Na salts, by treatment with EtONa , while BzOH is ethylated. From the mother liquids the small, water-sol. portion of I is extd. with abs. alc. A very small amt. is lost by the evapn. of the aq. soln. because of the slight volatility of I with steam. Traces of N are present in the small amt. of resin formed. An expt. with com. casein (Hamarsten) hydrolyzed 8 hrs. by boiling with HCl showed that practically all amino acid N was recovered. Since casein contains nearly all the amino acids known this result can be considered as a proof that the method is suitable for the quant. detn. of any amino acid. In ovalbumin (Hopkins) at least 91% of the N was recovered as NH_3 and amino acids, while according to the older methods about 40% of the glucosamine N remained unidentified. Combined with a less destructive method of hydrolysis benzoylation will lead to a better knowledge of the proteins. The purity of the products could be judged only indirectly. The mode of their prepn., the soly. in NaHCO_3 and the absence of coloring matter make contamination by humin substances and colloidal products of an incomplete hydrolysis improbable. Diketopiperazines and polypeptides may be present, but their N can be considered as amino acid N. The sepn. into the individual acids or at least into less complex mixts. may be feasible by fractionating the Et esters of I. In casein about 75% was ethylated to products b_1 up to 200° and separable by fractioning. M. J.

Histological observations on pancreatic secretion. E. S. HORNING. *Australian J. Exptl. Biol. Med. Sci.* **2**, 135-8(1925).—The zymogen grains of the pancreatic cells of the guinea pig are secreted as grains (globules) into the acini, where they are rapidly dissolved. They arise in the cells mainly from the filamentous mitochondria. This suggests the enzymic nature of the latter. They also seem to contain a lipoidal substance. The zymogen grains may be secreted, not only into the acinar ducts, but also into the pancreatic blood vessels. L. W. RIGGS

Chemical mechanism of the principal fermentations of glucose. M. LEMOIGNE. *Bull. soc. chim.* **37**, 1089-1106(1925).—The fermentations are classified into the following groups: (1) Total combustion when the glucose is transformed directly into CO_2 and H_2O . (2) Simple oxidation when the glucose is converted into gluconic and glycuronic acids. (3) Simple division (*dedoublement*), when one mol. of glucose gives 2 mol. of lactic acid. (4) Division and decarboxylation, which is the alcoholic fermentation. The reactions involving lactic and pyruvic acids, glycerol and acetaldehyde as intermediate or side products are discussed. (5) Division, decarboxylation and aldolization. In this division are considered (a) the butylic, butyric, acetic and β -hydroxybutyric fermentations, and (b) butyleneglycolic fermentation. L. W. RIGGS

Hormonal and pharmacologic influence on the oxygen consumption of the blood. I. Relations of the function of the thyroid to the oxygen consumption of the blood. EISHICHIRO TSUKAMOTO. *Tohoku J. Exptl. Med.* **6**, 286-98(1925).—The blood of a rabbit fed with thyroid prepn. shows an increase in its O consumption. In Basedow's disease the O consumption of the blood is increased. Similar changes are shown with blood which has been washed with physiol. saline soln. The action of the thyroid hormone is referred to the biologic properties of the blood corpuscles. L. W. R.

Photochemical action of hematoporphyrin. HANS GAFFRON. *Naturwissenschaften* **13**, 859-60(1925).—Appreciable quantities of hematoporphyrin in human blood causes "light" disease. It was now found that a soln. of this dye in serum (p_H 7.4), exposed to light, absorbs considerable quantities of oxygen, the latter oxidizing serum protein, to which the dye is attached. By a manometric method quantities as low as 0.001 mg dye in some cc serum can easily be detd. B. J. C. VAN DER HOEVEN

Examination of some gum enzymes. G. J. FOWLER AND M. A. MALANIKAR. *J. Indian Inst. Sci.* **8A**, 221-39(1925).—Qual and quant. detns. of the enzymes in gum arabic, myrrh gum and gum from the gum oleoregin of *Boswellia serrata* were made. All three contained diastase and oxidase, the latter being direct in the case of the last 2 gums. The diastases did not act on raw starch. None of the gums was hydrolyzed by its contained enzymes. The gums contained 3.03, 3.02, and 0.16% N, resp. J. J. WILLAMAN

• PEARSON, WALTER A. AND HEPBURN, JOSEPH H. **Physiological and Clinical Chemistry.** Philadelphia and New York: Lea & Febiger, 300 pp interleaved. \$4.00, net. Reviewed in *J. Franklin Inst.* **200**, 692-3(1925).

B-METHODS AND APPARATUS

STANLEY R. BENEDICT

An application of a rubber finger cot to medico-bacteriological researches. RUDOLF DITMAR. *Rev. gen. caoutchouc* **1925**, No. 15, 10.—A rubber finger cot is constructed with bands of red and blue litmus paper, so that on contact with any tissue the reaction of the medium can be detd. and a valuable clue to the nature of the microbial reactions can be obtained. C. C. DAVIS

Pyrotannic acid method for the quantitative determination of carbon monoxide in blood and in air.—Its use in the diagnosis and investigation of carbon monoxide poisoning. R. R. SAYERS AND W. P. YANT. *Bur. of Mines, Tech. Paper* **373**, 18 pp.(1925).—Application of the carmine color produced by HbCO and tannic acid for detg. CO in 0.1 cc. blood. 0.1 cc. blood is withdrawn from the finger, dild. to 2 cc., put into a special test tube, 0.04 g. tannic pyrogallic acid mixt. added, the tube inverted several times, allowed to stand $\frac{1}{2}$ hour and compared with standards made as described below in reflected daylight. The standards made from blood which, if kept in a cool place and airtight, will retain their permanence for one to two weeks, can be prepared from human or beef blood by mixing normal blood (diluted 1 to 10) with an appropriate amt. of blood (dild. 1 to 10) exposed to 3 to 5% CO before dild. From these solns. of approx. pure HbO₂ and HbCO, respectively, mixts. are made which total 1 cc. but vary from 0 to 100% HbCO in steps of 10. These solns. are contained in a test tube of $\frac{5}{16}$ " inside diam. of clear thin glass. To each tube is added 1 cc. of a mixt. of equal parts of a strictly fresh soln. of 2% pyrogallic acid and a 2% soln. of tannic acid after which the tube is inverted twice to insure thorough mixing. The tube is immediately sealed by pouring a little melted paraffin on the tube while it is immersed in cold water to prevent overheating. The temporary seal is later made permanent by covering with sealing wax. Permanent standards can be made from pigments which will keep indefinitely by matching with the blood standards thus prepared. CO detn. in the air may be carried out by equilibrating normal dild. blood (0.1 cc. to 2 cc.) with the sample of air under consideration for 15-20 min. When the equilibration is finished the blood is poured back into the test tube which matches those in which the standards described above have been placed and the pyrogallic tannic acid mixt. added and the HbCO detd. as before. After the detn. of the % of HbCO present in the blood, the percent of CO (pCO) in parts per 10,000 may be detd. with the aid of the formula, $pCO = [HbCO/(100 - HbCO)] \times (2093/300)$. In 0.01% CO the HbCO detn. is carried out to the accuracy of ± 0.005 while with 0.15% the accuracy is about ± 0.02 . A compact field app. is described which is durable, accurate and dependable for these detns. H. J. D., JR.

The preparation of hydroxyhemin. A. HANSIK. *Z. physiol. Chem.* **148**, 99-110 (1925); cf. *C. A.* **19**, 3089.—For the prepn. of pure hydroxyhemin the crude hydroxyhemin anhydride, hydroxyhemin or chlorohemin is first converted into the K salt by repeated treatment with alc. KOH, the salt then transformed into the corresponding hemin by AcOH, alc. (CO₂H)₂ or alc. H₂SO₄, and the product finally hydrolyzed by H₂O. Hydrolysis is, however, not complete and a slight acid residue, especially AcOH or H₂SO₄, remains. Without hydrolysis α -acetylhemins can be obtained, but the prepn. of oxalylhemins was unsuccessful, and the sulfate-hemin was further altered by the action of H₂SO₄. Derivs. of α -hemin are readily changed by acids and bases into the α -pseudo modification, the β -form, or other products which interfere with crystn. The α -form

is, however, not altered by brief treatment with alc. KOH and can thus be extd. from mixts. of the transformation products. α -Prepns. sometimes yield β -salts if the alc. KOH treatment is prolonged. A. W. DOX

Method for the determination of calcium and phosphorus in small amounts of blood. KARL MYRBACK. *Z. physiol. Chem.* **148**, 197-206(1925).—The detn. of Ca is essentially the deWaard method, and the detn. of P_2O_5 a combination of the Emblen pptn. and the Neumann titration method. A. W. DOX

Factors of error in performing blood sedimentation tests. T. H. MCGAVACK. *Hahnemannian Monthly* **60**, 653-62(1925).—The sedimentation time was detd. in 13 normal individuals, 36 obstetrical cases and 21 cases of disease. The time was decreased in all conditions in which evidence existed of toxic absorption or decrease in cell vol. percentage. However, so many, factors influence the detn. that it cannot be applied at the present time with any degree of accuracy in the differential diagnosis and prognosis of disease. A bibliography is appended. JOSEPH S. HEPBURN

A viscometric method for the quantitative determination of amylase. W. C. LAYSON. *Bull. Johns Hopkins Hosp.* **37**, 281-2(1925).—The activity of amylase in various substances may be detd. quantitatively by measuring changes in the viscosity of starch soln. A starch soln. (Lintner) 2.5 times as viscous as water is most suitable. This is added to 100 cc. distd. water, boiled 1 min. and then autoclaved at 18 lbs. pressure for 15 min. and filtered through muslin. The reaction is usually p_H 5.6. This soln. should be used within 24 hrs. after prepn. Ten cc. of this soln. is placed in each of 2 Ostwald viscometers immersed in a glass water bath at 34° and the time for 5 cc. to pass through the capillary tube detd. To one of the viscometers are added 0.1 cc. to 0.4 cc. of amylase prepn. and to the other an equal amt. of the same prepn. after it is boiled to act as control. The viscosity of these is detd. at intervals of 3 or more min. for a period of 1 to 2 hrs. and the results are plotted. G. F. REDDISH

Determination of traces of Pb in organs and the changes that take place in very dilute aqueous solutions of $Pb(NO_3)_2$ (BERNHARDT) 7.

C—BACTERIOLOGY

A. K. BALLS

Are there dextrin-fermenting yeasts? STAIGER AND W. GLAUBITZ. *Z. Spiritus-ind.* **48**, 320-1(1925).—A mash prepd. from rye by treating with 12% malt for 15 mins. at 60° was divided into 2 equal portions. One portion was cooled and divided to make 3 culture solns. of 300 cc. each. Three races of yeast were added to test their power of fermenting dextrin. One culture (a) was seeded with 5 g. yeast race M, (b) with 5 g. Pombe and (c) with 5 g. Mellacci. The other half of the original mash was treated by heating to 90° to destroy the diastase, then cooled, made up to vol. and divided into 3 portions of 300 cc. each and seeded as above. It was found that in the portion not heated to 90° race M fermented dextrin slightly, while Pombe and Mellacci fermented more dextrin than race M. In the portion heated to 90° none of the yeasts fermented dextrin. C. N. FREY

Effect of climate and other factors on the protein content of North Dakota wheat. C. E. MANGELS. *Cereal Chem.* **2**, 288-97(1925).—A survey of the wheat crops of 1921, 1922, 1923 and 1924 showed a high protein content in 1921 and 1923 and low in 1922 and 1924. Variation in rainfall was found not to have any effect on the protein content. High temp. in June and July characterized 1921 and 1923 when the protein content was high, while low protein years of 1922 and 1924 were characterized by subnormal temp. Low temp. in June and July are associated with high yields per acre, and the yield of protein in lbs. per acre was higher in 1922 and 1924 than in 1921-23. Subnormal temp. increases the growing season by delaying maturity and consequently a long growing season is associated with subnormal temp. and low av. protein. High protein wheat may be produced when climatic conditions favor low protein wheat if sweet clover be used as a preceding crop. Baking quality of flour of wheat showed less seasonal variation, due to compensation of varying quality in gluten. R. B.

Biochemistry of plant diseases. V. Relation between susceptibility to brown rot in plums and physical and chemical properties. J. J. WILLAMAN, N. C. PERVIER AND H. O. TRIEBOLD. *Bot. Gaz.* **80**, 121-44(1925); cf. *C. A.* **16**, 3932.—The plum varieties resistant to brown rot have a higher crude fiber content and a higher pentosan

content than the ones which are susceptible. The toughness of the skin and the firmness of the flesh decrease in all varieties as the ripeness proceeds, but it is most marked in the susceptible varieties. When the plums become ripe, and especially when over-ripe, these relations tend to disappear; and at these stages practically all varieties become susceptible to brown rot.

Physiological study of two varieties of *Ipomoea batatas*. G. R. JOHNSTONE. *Bot. Gaz.* 80, 145-67(1925).—Freshly dug sweet potatoes (Porto Rico and Triumph varieties) increase in their rate of respiration from the date of harvest until a max. is reached, then the rate gradually falls to a nearly const. level. Cured sweet potatoes do not reach so high a max. rate of respiration. Catalase, laccase, peroxidase and amylase are present, but not tyrosinase.

Relation between the development, structure and functioning of the nodules on *Vicia faba*, as influenced by the presence or absence of boron in the nutrient medium. WINIFRED E. BRENCILEY AND H. G. THORNTON. *Proc. Roy. Soc. (London)* 98B, 373-99 (1925).—In the absence of B, a defective vascular supply existed in the nodule on the broad bean, *Vicia faba*. The strands frequently were entirely absent, and, if present, were poorly developed and extended into the nodule for only a short distance. The nodules without vascular strands remained minute, and were usually buried in the cortical tissues; the bacteria failed to produce so-called "bacteroids"; and the number of nodules of macroscopic size were greatly reduced. When poorly developed strands entered the nodule, the amt. of tissue containing bacteroids was closely proportional to the extent of the strands. Very little N was fixed in plants with these defective nodules, the quantity fixed per nodule being less than one-tenth that fixed in normal plants. When vascular strands were absent from, or poorly developed in the nodule, the bacteria tended to become parasitic, attacking the protoplasm of the host, chiefly the more densely protoplasmic cells of the nodule. This change in the relationship between bacteria and host was probably due to a depleted supply of carbohydrates normally brought into the nodule by the vascular strands; as a consequence, the bacteria were compelled to utilize the protoplasm of the host as a source of energy. A bibliography is appended.

Synthesis of starch in plants in the presence of calcium and sodium salts. W. S. H. JIN. *Ecology* 6, 333-51(1925).—Leaves of plants were immersed in weak solns. of maltose or glucose to which varying amts. of CaCl_2 or NaCl were added. Different concns. were required to stop starch formation in different plants. Species growing on lime endure high concns. of CaCl_2 from 0.4 to 0.6 mol. These plants showed low tolerance to NaCl . Plants growing on soils low in lime are very susceptible to CaCl_2 . High concns. of Na are tolerated better by halophytes. A plant particularly resistant to the action of a salt will be placed at a considerable advantage on soils contg. that salt in abundance.

Variation of protein content of corn. IV. H. B. ARBUCKLE AND O. J. THIES, JR. *J. Elisha Mitchell Sci. Soc.* 41, 64-9(1925); cf. *C. A.* 17, 3726; 19, 2970.—The authors are convinced the protein content of corn cannot be changed by use of fertilizers. Climate affects the protein content of corn somewhat but type of soil affects it very little. Variation in inheritance seems to account for the great variation in different ears of the same variety. Corn with const. inheritance has a const. protein content. A. I. M.

E—NUTRITION

PHILIP B. HAWK

The mineral elements in animal nutrition. J. B. ORR. *Chemistry & Industry* 44, 964-70(1925).—A review.

The composition of the food and the need for vitamin. CASIMIR FUNK AND JUAN ANTONIO COLLAZO. *Chem. Zelle u. Gewebe* 12, 195-202(1925).—If pigeons which have been brought into vitamin-B equil. on a diet contg. 12.5% protein are changed to a food with a protein content of 25, 50 or 75% of protein, an increase in wt. occurs approx. proportional to the protein content. The converse occurs when the protein content is lowered and the carbohydrate is increased. This phenomenon is explained by the earlier conception of Funk that the metabolism of protein requires less vitamin B than that of carbohydrate.

Vitamin deficiency and pernicious anemia. N. R. DHAR. *Chem. Zelle u. Gewebe* 12, 225-7(1925).—The opinion is expressed that pernicious anemia can be traced to a lack of vitamins in the food chiefly B and C. It is probable that this disease could be cured by a vitamin-rich diet in the same way as scurvy and beriberi are.

Nomenclature of the vitamins. CASIMIR FUNK. *Science* 62, 157-8(1925).—It

seems advisable at this stage to sep. the active substances, known under the name of vitamins, into two groups, one group which contains nitrogen and is unstable to the action of alkalis to be designated as vitamines, with the original spelling retained, and another group, which does not contain nitrogen and is stable to the action of alkalis, to be designated as vitasterols. In the first class are included vitamins B (antineuritic), C (antiscorbutic), D (yeast growth promoting), and P (antipellagra). Under the classification of vitasterols are A (antixerophthalmic), E (antirachitic), and F (the reproduction vitasterol). H. J. DEUEL, JR.

Studies on the vitamin problem. IV. The influence of avitaminosis on the gastric digestion of white mice. FRANZ GROEBBELS AND FRANZ SPERFELD. *Z. physiol. Chem.* 148, 290-3(1925).—By feeding white mice a vitamin-free diet the formation of pepsin or its precursor is not inhibited, since after 10 days of such feeding much pepsinogen can be demonstrated in the gastric mucosa. On the other hand, an inhibition of pepsin secretion occurs, since the mucosa shows the same response in the digestion expt. as in starvation, *i. e.*, a storage of pepsinogen. Starvation following vitamin-free feeding appears to disturb the formation of pepsinogen, while this is not the case if starvation is preceded by a normal diet. A. W. DOX

Comparative nutritional value of white and whole wheat flour. C. U. MOORE AND JESSIE L. BRODIE. *Arch. Pediatrics* 42, 572-7(1925).—When white mice were fed properly balanced, chemically identical diets, the gain in body wt. was 4 times as great on whole wheat flour as on white flour. The consumption of food was twice as great on the whole wheat flour ration as on the white flour ration. The mice receiving white flour frequently developed paralysis and some died; their fur became clumped and abnormally oily; and they had a decreased resistance to cold weather. When they were transferred to the whole wheat flour ration, they rapidly regained body wt.; and their fur became normal. The white flour is deficient in vitamin B. From the viewpoint of nutrition (cost of food per unit gain in body wt.) whole wheat flour is far superior to white flour. A bibliography is appended. JOSEPH S. HEPBURN

Comparison and interpretation on a caloric basis of the milk mixtures used in infant feeding. G. F. POWERS. *Am. J. Diseases Children* 30, 453-75(1925).—The diln of milk mixts. with water affects the calories per unit mass, but not the percentage relationships of protein, carbohydrate and fat in the total calories. The addn. of an energy-yielding nutrient to milk affects not only the total calories per unit mass but also diminishes the proportional representation in the total calories of the protein, lactose and fat. All milk mixts. used in infant feeding, reduced to the caloric percentage formulae, are identical excepting in concn., degree of denaturation and in qual. differences. Successful feeding mixts. contain 60% of the total calories in whole milk and 40% in added carbohydrate. I. NEWTON KUGELMASS

Vitamin B in tikitiki extract prepared by the Philippine Bureau of Science. F. O. SANTOS AND E. G. COLLADO. *Philippine Agr.* 14, 243-6(1925).—Tikitiki (rice polishings) are high in vitamin B as well as antineuritic vitamin potency. A. L. M.

Experimental rickets in rabbits. HARRY GOLDBLATT AND A. A. MORITZ. *J. Exptl. Med.* 42, 499-506(1925).—Rickets have been produced experimentally in rabbits by the administration of diets deficient in the antirachitic org. factor and P but with a high Ca content. Cod-liver oil added to these ricket-producing diets prevented the development of rickets in rabbits. C. J. WEST

Deficient and surplus consumption of vitamin B: their quantitative relation to weight changes and to vitamin storage in adult pigeons. J. D. PILCHER AND TORALD SOLLMANN. *J. Pharmacol.* 26, 203-13(1925).—The retarding action of yeast administration on the loss of wt. of adult pigeons on a rice diet bears a simple proportional relation to the daily dosage of the yeast ext. (a parabolic curve). The curve of wt. loss on an exclusive rice diet is practically parallel whether it has been preceded by a period of complete or of partial vitamin B deficiency, or whether the preceding period contained full maintenance ration of yeast. If a surplus of yeast is given in the preceding period, the loss of wt. may be delayed by a week; *i. e.*, a week's (7 to 10 days) supply of vitamin B may be stored on a surplus consumption; but none is stored on a maintenance or inadequate consumption. The storage cannot be prolonged beyond this period by increasing the dosage of yeast in the preceding period. Corn diet also provides a store of vitamin that protects against weight loss for the same period (10 days). Liability to polyneuritis is apparently an individual trait, so that pigeons that show neuritis on the 1st expt. with rice and have been cured by corn diet will usually respond by neuritis when again subjected to corn diet. C. J. WEST

F—PHYSIOLOGY

ANDREW HUNTER

Phosphate and calcium content of the blood of guinea pigs and rats during varying administration of C- and A-vitamin. HANS V. EULER AND KARL MYRBACK. *Z. physiol. Chem.* **148**, 180-96(1925).—Guinea pigs are especially sensitive to the lack of C-vitamin and develop typical symptoms of scurvy, while rats respond less readily to lack of C but show rachitic changes with deficiency of A. Changes in the Ca and PO_4 content of the blood following withdrawal of C and A, resp., from the diet of the two animals were detd. The blood of normal rats averaged 0.069 mg. Ca per g. No noteworthy changes were observed in the vitamin expts. The normal blood contained 0.24 mg. PO_4 per g., the serum 0.21 mg. per cc. and the corpuscles from 1 g. of blood 0.105 mg. The values for PO_4 after the vitamin expts. were: excessive feeding of C, blood 0.0264, serum 0.229; without C, serum 0.16, corpuscles 0.067; irradiated peanut oil, blood 0.221, serum 0.205, corpuscles 0.126; without peanut oil, blood 0.171, serum 0.219, corpuscles 0.013. PO_4 values for normal guinea pigs were: blood 1.15, serum 0.31, corpuscles 0.91. After 18 days of C-free diet and development of scurvy these values became: blood 0.87, serum 0.32, corpuscles 0.76. Both total and inorg. PO_4 decreased markedly, the decrease being most striking with simultaneous deficiency of both vitamins. This decrease of phosphate in the blood is suggested as a quant. criterion in C-vitamin investigations on guinea pigs. A. W. Dox

Comparative determinations of the phosphate, calcium and magnesium content in the tibia of rats and guinea pigs. HANS V. EULER AND ROBERT JOHANSSON. *Z. physiol. Chem.* **148**, 207-10(1925).—The tibia of young rats showed a Ca: PO_4 ratio of 0.714, and of guinea pigs 0.66. A. W. Dox

The hexose concerned in biological carbohydrate metabolism. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* **148**, 211-7(1925).—The fact that the glucose resulting from cleavage of zymophosphate, glycogen, etc., in metabolic processes is utilized much more rapidly than either the α - or β form postulates the transitory existence of an additional and less stable form which is designated γ -glucose. Further evidence in support of this assumption is furnished by fermentation expts. When glycogen is fermented in the presence of amylase, the ratio of CO_2 evolved to the glucose concn. of the medium at various stages of the fermentation is about twice that of parallel expts. with ordinary glucose. A. W. Dox

Muscular exercise, lactic acid and the supply and utilization of oxygen. XI. Pulse rate and oxygen intake during the early stages of recovery from severe exercise. R. J. LYTCHGE AND J. R. PEREIRA. *Proc. Roy. Soc. (London)* **98B**, 468-79(1925). The decrease in consumption of O_2 and in heart rate during recovery from severe exercise begin abruptly, or almost abruptly, when bodily movements cease. Consumption of O_2 decreases more rapidly than the heart rate, probably as a result of the suddenly decreased circulation rate of the blood. The intake of O_2 per heart beat decreases immediately and rapidly when exercise ends, even when there is still a considerable demand for O_2 by the tissues. **XII. Note on the technic of determining the resting oxygen intake while breathing concentrated oxygen mixtures.** J. R. PEREIRA. *Ibid* 480-4. The intake of O_2 is practically the same whether (a) air be breathed and the expired air be analyzed by means of the Haldane app., or (b) almost pure (95 to 98%) O_2 be breathed and the expired air be analyzed by means of Krogh's app. "The greater O_2 consumption found at rest while breathing rich O_2 mixts., the expired air being analyzed with the Haldane's gas-analysis app., is due to an error occurring in this case in the Douglas bag technic, viz., the incorrect assumption that the total amt. of N_2 is the same in the inspired as in the expired air. If the amts. of the inspired as well as of the expired air be measured separately by the same meter, no assumption being made as to the constancy of the N_2 , the results obtained as to the O_2 used are identical, whether breathing air or strong O_2 mixts." JOSEPH S. HEBURN

Surface tension theory of muscular contraction. A. V. HILL. *Proc. Roy. Soc. (London)* **98B**, 506-15(1925).—When a muscle fiber 1 cm. long develops a force of 1 dyne, 1.46×10^{-11} g. or almost 10^{11} mols. of lactic acid are produced. These mols. would cover an area of approx. 2.1×10^{-4} cm.² if spread out in a continuous monomol film. If the mech. response of muscle were due to a change of surface tension produced by a film of lactic acid, the requisite coeff. of surface tension would be approx. 4800 dynes per cm., or approx. 230 times the tension of an interface of olive oil and water, therefore an impossible value. In a max. contraction of a frog muscle in good condition, sufficient lactic acid is produced to form a continuous monomol film with an area approx. equal to that of the surface of the fibers composing the muscle, or to 2% of the

surface of the ultimate fibrils. Each gram of the muscle would yield approx. 0.033 mg. of lactic acid which would occupy an area of approx. 470 cm.² J. S. H.

Development of blood plasma. I. The genesis of coagulable material in embryo chicks. J. W. PICKERING AND R. J. GLADSTONE. *Proc. Roy. Soc. (London)* 98B, 516-22 (1925).—The plasma of early embryos contains an excess of material which is protective against the inception of clotting, but does not possess antithrombic properties. At the stage of development prior to the appearance of prothrombin, embryonic blood yields antithrombic material on heating to 60°. Inception of coagulation of embryonic blood may occur at room temp. prior to the agglutination and lysis of thrombocytes. Embryonic and hemophilic bloods are characterized by certain similarities of behavior. A higher concn. of Ca ions is required to permit clotting at room temp. than suffices at 40°. Apparently the impact of a definite number of Ca ions in a definite period of time is an essential factor in the inauguration of coagulation. An increase in the H-ion concn. of the embryonic plasma, produced by its neutralization to litmus, causes clotting at room temp.; the H ions apparently function as a catalyst and cause clotting. •

Recent advances in science: physiology of reproduction. JOHN HAMMOND. *Science Progress* 20, 232-6(1925).—Review of recent work on the influence of the internal secretions on reproduction.

JOSEPH S. HEBBURN

The lipid content of the corpus luteum. HERMSTEIN. *Arch. Gynaekol.* 124, 739-70(1925).—Chemical analyses were made of the corpus luteum from 12 human ovaries at three stages of development. The weight and H₂O content were found to vary but were independent of the stage of development. There was no relation between H₂O content and total lipid content. The total lipid content varied little, though it was slightly higher just before the menses. At height of development the corpus luteum contained chiefly cholesterol, cholesterol esters and phosphatids. After the menses the complex lipoids are less abundant and more fatty acids, neutral fat and soaps are present. Phosphatids are abundant in all phases, particularly at the height of development. The chemical study in general confirms histological studies on the corpus luteum, except that more neutral fats and fatty acids are found in the earlier stages by chemical analysis and phosphatids are found abundantly in the retrogressive phase. H. F. H.

The sexual glands and metabolism. III. The influence of injections of testicular or ovarian emulsions upon the nitrogen and gaseous metabolism of dogs and rabbits. V. KORÉNCHEVSKII. *Brit. J. Exptl. Path.* 6, 158-72(1925).—Exptl. data and observations on patients indicate that testis and ovarian tissue proper contain a hormone or hormones which increase N metabolism but that of corpora lutea decrease it. The latter are only temporary glands, therefore castration in females probably may change the metabolism in either direction according to the content of corpora lutea in the ovaries removed. Expts. on thyroidectomized animals show that in spite of the close interrelationship between sexual and thyroid glands, changes in N metabolism produced by sexual hormones are not exclusively caused by an increased stimulation of the thyroid gland. There was little or no effect on gaseous metabolism of exts. from testis, ovary or corpora lutea.

HARRIET F. HOLMES

A contribution to the origin of urobilin. C. D. DE LANGEN. *Geneeskundig Tijdschr. Nederland. Indie* 65, 461-4(1925).—Urobilin was found in the cerebrospinal fluid in a case of brain hemorrhage in a newborn. This case as well as a few others described in the literature find no explanation in the enterogenous theory. Animal expts. may not be conclusive, since according to Beyers neither urobilin nor bilirubin occurs in the huge hematoma of domestic animals.

MARY JACOBSEN

Glucose, cholesterol and calcium. Their content in the blood of children and their interrelation in the chemical formula of the blood. GIOVANNI DE TONI. *Pediatrics* 33, 987-95(1925).—The serum of 6 normal fasting children of from 1 to 3 years contained in g./1000: 0.9-1.12 (av. 1.0) glucose (I) (Folin-Wu), 1.52-1.97 (1.65) cholesterol (II) (Grigaut) and 0.10-0.12 (0.115) Ca (III) (de Waard). In 28 children over 3 and under 12 years I was 0.8-1.24 (1.05), II 1.47-2.10 (1.74), III 0.1-0.115 (0.110). Generally II and III appear to be higher in children. Sometimes a higher III was accompanied by a raised II and I, in other cases no such relation was present. Comparative detns. in diseased children were inconclusive on account of the variety of the diseases. M. J.

Blood chemistry of the newborn. O. H. SHERMAN, G. W. PUCHER AND H. R. LOHNES. *Am. J. Diseases Children* 30, 496-503(1925).—Blood detns. on 23 newborns the first, third and fifth days showed in the so-called inanition fever a marked increase of blood urea N and amino acids, a marked acidosis but no decrease in the water content. Inanition fevers are not due to increased blood salt concn.

I. N. K.

Inorganic phosphorus in the blood of the newborn. E. A. RIESENFELD, I. HANDEL-

MAN AND A. R. ROSE. *Am. J. Diseases Children* 30, 646-58(1925).—1439 inorg. P detns. were made on the blood of mothers and their newborn infants. The av. of the mother's inorg. P at delivery was 3.10 mg., ± 0.019 mg. % and the newborn infant's was 412 mg., ± 0.028 . No difference was found between the white and negro mothers' or infants' blood. The inorg. P was not affected by the previous habitat of the mother, the time the mother spent out of doors during gestation. The seasonal variation of inorg. P parallels that of rickets.

I. NEWTON KUGELMASS

Methemoglobin restitution. I. *In vitro*. KYUICHI SAKURAI. *Arch. expll. Path. Pharm.* 107, 287-315(1925).—If the blood pigment of freshly defibrinated blood is to some extent converted into methemoglobin by means of amyl nitrite a spontaneous reversion of the methemoglobin occurs simply upon standing. The rate of this spontaneous change is particularly abrupt at first but gradually diminishes. The process of reversion is complete only when the amts. of amyl nitrite added are small; with the addn. of 0.05% or more the original content of oxyhemoglobin is never reached. The reversion process is markedly stimulated in both rate and degree by the addn. of organ. tissues, liver and lung being most active in this respect. Muscle and spleen are less active. With liver or lung present a complete reversion of the methemoglobin produced by the addn. of 0.05% of amyl nitrite is complete, with muscle or spleen a complete restitution is not attained. $\text{Na}_2\text{S}_2\text{O}_3$ favors the reversion; Na succinate and NaCl are inactive. No change in the reversion velocity is effected by conducting air, H, or N through the material. CHCl_3 does not impair the activity of the process. The stimulating effect of organ materials and of thiosulfate is apparently associated with reduction processes.

G. H. S

G—PATHOLOGY

H. GIDEON WELLS

Tumor immunization. N. WATERMAN. *Nederland. Tijdschr. Geneeskunde* 69, II, 577-83(1925).—Mice treated with insulin are less susceptible to the development of a tumor than normal mice following the inoculation of the same tumor cells. This important result is obtained from 3 series of expts. on mice. The amount of insulin injected was 0.2-0.5 cc. of a 0.01 normal standard solution (of the old type of units), daily for a period of 14-40 days previous to inoculation of tumor cells. In the animals treated with insulin, the tumor appears very much later than in not treated animals, and when it appears it has a different appearance, being dark red, while the regular tumor of the kind employed is greyish or light red, as observed in hundreds of control animals, also, in former exptl. work. Those dark red tumors contain only little tumorous parenchyma but much extravasated blood. W. discusses former expts. on spec and non-spec tumor immunization and assumes that in the case of immunization by means of tissue expts. an hormonal influence prevailed as well.

R BEUTNER

Serial refractometric and viscometric examinations of the blood serum in tuberculosis. M. GANSSLEN AND O. MAIER. *Z. Tuberk.* 40, 321-4(1924).—Refractometric exams. of the blood in all stages of tuberculosis revealed normal values. Serial exams. in fatal cases showed a gradual diminution before death. The albumin-globulin relation gave higher values in severe cases, with an increase of globulin in unfavorable and a decrease in improving cases. In meningitis and miliary tuberculosis globulin increase was absent. Marked tuberculin reactions, and intercurrent diseases caused a temporary increase in globulin and a lowering of the refraction.

H J. CORPER

The diagnosis of active tuberculosis, especially with the Wassermann serum reaction. HERTA KALCHER AND ARTHUR SONNENFELD. *Z. Tuberk.* 40, 420-31(1924).—The urochromogen reaction, protein content and globulin to albumin relation in the serum, is unserviceable for the diagnosis and prognosis of tuberculosis. The leucocyte count does not deviate from normal in active tuberculosis, lymphopenia is not constant, and a shift of the leucocyte picture (Arneth) to the left favors activity. Persistent lymphopenia and shift to the left of the neutrophile picture in the absence of eosinophilia is unfavorable prognostically. Accelerated erythrocyte sedimentation rate is not specific for tuberculosis. A normal sedimentation does not exclude active tuberculosis. In only 60% of cases did Wassermann's tuberculosis test show agreement between the serological and clinical findings.

H. J. CORPER

Combined tuberculin testing and erythrocyte sedimentation rate determinations in pulmonary tuberculosis. TEGMEIER. *Z. Tuberk.* 40, 442-8(1924).—Larger tuberculin doses were used than those in the original Gräfe and Reinwein combined tuberculin and sedimentation test. High temp. persisted for some time after the tuberculin injection without influencing the sedimentation rate. Definite changes in the sedimen-

tation rate can occur with active tuberculous processes but the absence, or slight changes, does not exclude active processes. A definite dose of old tuberculin could not be outlined, but observations over longer periods with increasing dosage are recommended.

H. J. CORPER

The cholesterol content of normal pigeons, of those poisoned with hydrocyanic acid and of those suffering from beriberi. N. MESSERLE. *Z. physiol. Chem.* **419**, 103-10 (1925).—The kidney, liver, brain and breast muscle of pigeons suffering from beriberi have a considerably higher cholesterol content than the same organs of normal pigeons. The difference, which is not merely relative, is greatest in the brain and breast muscle and least in the kidney. Pigeons poisoned with HCN also show an increase in cholesterol content but somewhat less marked than that of beriberi pigeons. The increased cholesterol content is probably associated with respiratory insufficiency and represents a secondary effect.

A. W. DOX

Buffer solutions in intestinal diseases. J. S. HEPBURN AND H. M. EBERHARD. *Am. J. Med. Sci.* **166**, 244-9 (1923).—Rectal injection of buffer solns. (phosphate buffer of p_H 8.043, or citrate buffer of p_H 12.364) in cases of chronic saccharo-butyric infection has produced a marked improvement in both the subjective and the objective symptoms. These buffers neutralize the intestinal acidity without the production of gas, and, therefore, are more suitable than $NaHCO_3$ for this purpose. JOSEPH S. HEPBURN

Buffer solutions and their use in intestinal diseases. J. S. HEPBURN. *J. Am. Dietetic Assoc.* **1**, 55-9 (1925).—A 0.4 N soln. of Na metasilicate, which has a p_H of 12.56, may be used as a buffer in the treatment of intestinal diseases. The reserve alkalinity, which becomes available in passing to a p_H of 7.0, is almost 25 times as great in a given vol. of this soln. as in the same vol. of a citrate buffer soln. of p_H 12.364. See preceding abstr.

JOSEPH S. HEPBURN

Inhibitory effect of blood serum on hemolysis. II. ERIC PONDER. *Proc. Roy. Soc. (London)* **98B**, 484-93 (1925).—The inhibition of hemolysis by serum is probably due to the formation of a loose phys. compd. between the lysin and the serum proteins. The reaction is not appreciably influenced by temp. within the exptl. range. J. S. H.

Cytology of tar tumors. R. J. LUDFORD. *Proc. Roy. Soc. (London)* **98B**, 557-77 (1925).—An elaborate study, with bibliography, of the tumors which are produced by regularly painting the skin of mice with tar.

JOSEPH S. HEPBURN

A physico-chemical study of the colloidal benzoin reaction. The benzoin-globulin complex. A. PAPAIOANNO. *Compt. rend. soc. biol.* **93**, 590-2 (1925).—The pptn. of globulin by colloidal benzoin is not dependent strictly upon the p_H of the soln. S. M.

Cholesterol in diabetes with arteritis. LABBÉ AND HEITZ. *Ann. med.* **18**, 108 (1925); *J. Am. Med. Assoc.* **85**, 1259.—A study of 19 cases showed that an exaggerated amt. of cholesterol in the blood of these patients does not seem to be connected with liver disturbances, albuminuria, the arterial pressure or syphilitic lesions. Cholesterol-emia is more pronounced in grave cases with acidosis, or with deficient permeability of the arteries, coinciding with reduction or abolition of the oscillometer findings. The cholesterol content is particularly high in diabetics affected simultaneously with aortitis and arteritis. Arterial obliteration in diabetes is due to localization of cholesterol in the tunica intima. While Na citrate did not display any action on the cholesterol content, insulin markedly reduced its amt.

L. W. RIGGS

Glucemia and cholesterolemia. LANDAU, *et al.* *Ann. med.* **18**, 143 (1925); *J. Am. Med. Assoc.* **85**, 1259.—A study of 16 persons, presumably normal, indicated that food rich in cholesterol and free from carbohydrates increased the content of sugar and cholesterol in the blood. Adrenaline injection, or ingestion of a large dose of sugar, raising the glucemia curve, reduced the cholesterolemia. Hunger increased the cholesterol content of the blood within the first 36 hrs., while lowering the glucemia.

L. W. RIGGS

Source of the protein in the albuminuria of experimental nephritis. C. H. KELLAWAY, G. F. S. DAVIES AND F. ELEANOR WILLIAMS. *Australian J. Exptl. Biol. Med. Sci.* **2**, 139-49 (1925).—In acute U nephritis in cats, where the damage is predominantly tubular, there is present in the urine a definite proportion of sol. protein other than that derived from the plasma, and apart from casts and epithelial debris from the tubules.

L. W. RIGGS

Immediate metabolic disturbances following deep Röntgen-ray therapy. II. Prevention and treatment of untoward reactions. H. P. DOUB, ADOLPH BOLLIGER AND F. W. HARTMAN. *J. Am. Med. Assoc.* **85**, 1299-1303 (1925); cf. *Am. J. Roentgenology* **13**, 54-64 (Jan., 1925).—In the study of 150 patients, treated with a modern deep therapy app., including a water-cooled tube, a high percentage of acute irradiation sickness was found. The rapidly developing alkalosis, and the continuation of this condition after

large doses, are confirmed by the detn. of the p_{H} of the plasma and of the urine, and by use of indicators in the tissues. A study of the expired air showed that the alkalosis is not a result of tissue oxidation or washing out of CO_2 . Expts. with dogs to find agents to counteract these disturbances proved that HCl , NH_4Cl and NaCl had but little effect. The first two of these drugs combat the alkalosis but not the sickness. Some other factor than alkalosis is concerned in the sickness. CaCl_2 , Ca lactate and morphine were beneficial. Morphine prevented the reaction in dogs and was helpful in patients treated over the abdomen. L. W. RIGGS

The etiology of incrustated cystitis with alkaling urine. B. H. HAGER AND T. B. MACARTH. *J. Am. Med. Assoc.* **85**, 1352-5(1925).—It appears that the inorg. salts which are deposited in the mucous membrane in cases of incrustated cystitis with alk. urine are due to a secondary invader, a Gram-negative bacillus, which in its growth liberates an enzyme, a urease capable of converting urea into NH_3 , thereby causing the alky. of the urine. The resulting alky. ppts Ca , Mg and NH_4 salts. The source of the bacillus (*Salmonella ammoniacae*) is the gastro-intestinal tract, and incrustated cystitis with alk. urine is caused by the implantation of the bacillus in a bladder which is already the seat of some inflammatory or tumorous lesion. Incrustated cystitis can be reproduced by expt. in lab. animals. L. W. RIGGS

Chemical analysis of sweat. A preliminary study. R. E. BARNEY. *J. Am. Med. Assoc.* **85**, 1373-5(1925); cf. Riggs, *C. A.* **6**, 505; Plaggemeyer and Marshall, *C. A.* **8**, 1144.—Fourteen normal subjects and 15 patients with eczema, psoriasis, etc., furnished the sweat which was collected in rubber blankets, and was analyzed for total solids and the usual N-partition products by standard methods. There is an apparent diminution in the output of the N constituents of the sweat in so-called senile eczema. This important finding may have an important bearing on the etiology of this condition. The 6 cases of psoriasis show no change from the normal. L. W. RIGGS

The excretion of neutral red into the human stomach. ASHER WINKELSTEIN AND J. M. MARCUS. *J. Am. Med. Assoc.* **85**, 1397-8(1925). A study of 46 cases showed that patients with normal or subnormal free HCl figures excrete the dye in a fairly const. av. time of 21 min. In hyperacidity the time of appearance of the dye is hastened to 17 min. In gastric achylia the excretion time is prolonged to 60 min. or more. In most cases the dye does not appear in the stomach. L. W. RIGGS

Modified physiological processes following the total removal of the liver. F. C. MANN. *J. Am. Med. Assoc.* **85**, 1472-5(1925). The blood sugar decreases from the instant the liver is removed. Muscle glycogen decreases concomitantly. When the blood sugar falls to a certain level the characteristic symptoms associated with low blood sugar appear, and if glucose is not administered, the animal will die in a condition of hypoglycemia. The proper administration of glucose prevents these symptoms and prolongs the life of the animal many hrs. until a different condition develops and the animal dies from causes not yet detd. The action of glucose in the hypoglycemic condition is sp. The decrease in blood sugar following hepatectomy also occurs in the condition of hyperglycemia that follows the extirpation of the pancreas. The transitory hyperglycemia that follows the administration of adrenaline, production of asphyxia and similar procedures does not occur after hepatectomy. An animal will die following the development of hypoglycemia with a considerable amt. of glycogen still present in the muscles. If the blood sugar level is maintained above normal in the hepatectomized animal, muscle glycogen will increase. Urea formation ceases immediately after removal of the liver. The amino acids, which normally would have entered into the process of urea formation, accumulate in the blood and, if the kidneys are active, are excreted in the urine. Uric acid is not destroyed, and it actually accumulates in the blood and tissues or is excreted in the urine if renal activity is maintained. A yellow pigment accumulates in the hepatectomized animal which gives a positive reaction to the chem. tests, and the spectrophotometer tests for bilirubin. L. W. RIGGS

Role of the capillaries in nephritic water retention. I. RUSZNYÁK AND D. KELLNER. *Magyar Orvosi Archivum* **26**, 277-83(1925).—The detn. of changes of refraction and salt content of the serum as well as the no. of red blood cells with nephrectomized rabbits give the same results even if the animals receive at the same time $\text{UO}_2(\text{NO}_3)_2$ and $\text{C}_6\text{H}_5\text{NO}_2$. Consequently, corresponding with the results of Bence, and in contrast to those of Richter, no active role of the capillary wall can be proved in the distribution of water in the body. L. W. RIGGS

Histological genesis of tar carcinoma. B. MELLY AND L. ORNSTEIN. *Magyar Orvosi Archivum* **26**, 306-20(1925).—Expts. with white mice showed that brushing an area with tar so as to produce chronic irritation is not the real cause but only one factor

in the production of epithelial tumors. The alterations in the internal organs, *i. e.*, nephritis, amyloidosis of the spleen and the taking up of tar granules through the reticulo-endothelial app. all prove that the changes produced by the tar are not localized in the skin.

L. W. RIGGS

The alkali content of the blood serum in healthy and diseased children. J. CSAPÓ. *Magyar Orvosi Archivum* 26, 321-4(1925).—A new method is given for the detn. of the alkali content of the blood serum. One cc. of serum from a healthy child contains on the av. the equiv. of 4.8 cc. of 0.01 N alkali of which 1.4 cc. represents free alkali and 3.4 cc. the alkalies combined with albumins. The alkali content of the blood serum changes according to the albumin content. In 100 cc. of blood serum 60 cc. 0.01 N alkali content corresponds to 1% albumin. This is called the alkali-albumin quotient. This quotient and the alkali content are markedly decreased in tuberculosis. **Acid fixation of the blood of healthy and diseased children.** J. CSAPÓ AND G. MIHALOVICS. *Ibid* 325-9.—The total acid fixation of the blood and plasma were detd. by means of the Bosanyi-Csapó method and the relation between plasma and corpuscular elements by means of the hematocrit procedure. With healthy children 1 cc. blood fixes 14-15 cc., and 1 cc. of plasma 7 cc. 0.02 N acid. The acid fixation of the blood increases or diminishes, resp., according to the red blood cell content. From the acid fixation of the blood and the plasma, as well as from the relation of the plasma to the corpuscular elements, could be calcd. the fixed acid quantity corresponding to 1 vol.-per cent of red blood cells, which amounts with healthy children to 0.27-0.31 cc. 0.02 N acid. This figure is called the acid-erythrocyte-quotient. With some children suffering from acute and chronic feverish diseases, both the acid-erythrocyte-quotient and the total acid-fixation capability of the blood was diminished, with other cases it remained normal. **Alkali fixation of the blood serum.** J. CSAPÓ AND S. HENSZELMANN. *Ibid* 330-4.—The alkali fixation of the blood serum was detd. electrometrically for healthy and for diseased children. With the former the 1% of albumin of 100 cc. serum fixes 95 to 100 cc. 0.01 N alkali. Tuberculosis and pleurisy decrease the quantity of alkali corresponding to 1% albumin. The alkali fixation of the serum is less than the acid fixation. This is because the alkali-fixing property of the serum proteins has been engaged partly by the original alkali contents of the serum.

L. W. RIGGS

Oxaluria. F. PICCININNI AND E. LOMBARDI. *Riforma Med.* 41, 726(1925); *J. Am. Med. Assoc.* 85, 1262.—P. and L. present data collected independently which demonstrate that a special strain of the colon bacillus sometimes acquires the property to produce $H_2C_2O_4$. This strain continues to produce $H_2C_2O_4$ in the test-tube, and also in persons free from oxaluria who after ingesting cultures of this strain show $H_2C_2O_4$ in the urine

L. W. RIGGS

Basal metabolism. J. STEPHANI. *Schweiz. med. Wochschr.* 55, 732(1925); *J. Am. Med. Assoc.* 85, 934.—The av. consumption of O is 6.16 cc. per min. per kg. of body wt. in the normal male, and 4.98 cc. in the female both at 760 mm. of Hg. During menstruation the latter figure is decreased about 14%. In mild cases of *exophthalmic goiter* the increase of the metabolic rate may be within the normal limits of 15%. An av. of 2% of the amt. of O that passes through the lung is absorbed in normal persons. This percentage is higher in slender persons and in toxic goiter, and is lower in the obese.

L. W. RIGGS

The blood sugar level and the adrenaline content of the suprarenals of the rabbit in diphtheritic intoxication. SHOZO MIKAMI. *Tohoku J. Exptl. Med.* 6, 299-324 (1925).—Intravenous administration of the diphtheria poison invariably causes hyperglucemia in the normal nourished rabbit, when the toxic quantity is so large that the rabbit dies within 24 hrs. following the injection. The blood sugar content begins to increase immediately after injection, reaches the max. in 3 to 5 hrs. and then decreases gradually. The poisoning depletes the adrenaline storage of the suprarenal glands. The loss is small in the first hrs., but becomes suddenly remarkable about the 6th hr., then the loss falls off so that the normal value is shown at the 8th to 9th hr. of poisoning. Double splanchnectomy arrests completely the occurrence of hyperglucemia as well as the adrenaline exhaustion, so they are of central origin. When the dose of the toxin is selected so that the rabbit can live over one day or more, though somewhat moribund, the hyperglucemia does not appear on the day of inoculation, but in 24 hrs. or later after injection hypoglucemia is unmistakably observed, at which time the suprarenal adrenaline and liver glycogen diminish to a marked degree. The double splanchnectomy cannot protect the animal from a diminution of these 3 substances.

L. W. RIGGS

Behavior of antigens in the animal body, KAKUZO SAKURABAYASHI. *Tohoku J. Exptl. Med.* 6, 390-3(1925).—Well washed pulp of organ cells after intravenous in-

jection in the rabbit disappears much more quickly than serum, and generally is not detectable directly after the injection.
L. W. RIGGS

H—PHARMACOLOGY

ALFRED N. RICHARDS

Treatment of diabetes by raw fresh gland (pancreas). R. CARRASCO-FORMIGUERA. *Brit. Med. J.* 1925, II, 552-3.—Raw fresh pancreas does not affect in the slightest a glucosuria which is rapidly reduced by a moderate dose of insulin. A. T. C.

Experimental investigation concerning the double effect of calcium on the vegetative nervous system. E. BARÁTH. *J. Nervous Mental Diseases* 62, 261-4 (1925), cf. *C. A.* 19, 347.—A résumé of work already published. In tests on hungering and resting individuals (normals and slightly pathological) injection of 5 cc. 10% CaCl_2 intravenously produces a double effect: There is an immediate marked slowing of pulse rate, Aschner's oculocardiac test becomes positive or increasingly positive, and the blood pressure increases 10 to 20 mm. (often with an initial depression). After 5 to 10 min. the pulse is again normal and Aschner's test negative. After, frequently, an initial depression, the blood sugar increases. B. concludes that in contradiction to the results of expts. on surviving organs the effect of Ca on man is manifested by a double reaction, an initial vagus excitement of short duration followed by less strong sympathetic excitement of longer duration (shown by the increase of blood pressure and sugar, and occasional adrenergic mydriasis). A. T. CAMERON

The biocatalysts of carbohydrate metabolism. II. H. V. EULER, E. JORPES AND K. MYRBÄCK. *Z. physiol. Chem.* 149, 60-4 (1925).—Co-enzyme solns. of the highest activity thus far obtained when injected into fasting rabbits showed no insulin action whatever and no toxic effect. A. W. DOX

The binding of complex bismuth salts in the serum. HUGO BAUER AND EDUARD STRAUSS. *Z. physiol. Chem.* 149, 19-29 (1925).—Sol. complex Bi salts (Na mono- and tribismuthyltartrates, glycerol-Bi, mannose-Bi) when dissolved in serum remain partly in soln. as salts, while another part enters into combination with the euglobulin fraction. Even when a large excess was used the Bi was never found combined with pseudoglobulin or albumin. The partition of the complex Bi compd. between the alkali salts and the euglobulin is detd. by an equil. which becomes displaced in one direction or the other according to the reaction. It is probable that the Bi which circulates in the blood is bound to the euglobulin fraction of the serum. A Bi compd. which is sol. in H_2O and dialyzable becomes bound to euglobulin only to a limited extent. This part, however, circulates with the blood and thus reaches the destination for its therapeutic action, while the remainder is rapidly excreted. It is possible that the latter contributes nothing to therapeutic action but on the contrary is responsible for toxic action. A. W. D.

Diffusion of mercury salts injected sub-conjunctivally. S. DEBENEDETTI. *Arch. sci. med.* 47, 261-73 (1925).—Sub-conjunctival injections of HgCl_2 solns. in white rabbits give rise to fixation of the Hg in organic combination mainly in the sub-conjunctival tissue, resorption taking place as in other parts of the body. Penetration is mechanical and only during resorption does it pass into the blood vessels serving the deeper tissues of the eye-ball. Fixation of the Hg in these tissues does not occur. M. H.

Alcohol and human efficiency: experiments with moderate quantities and dilute solutions of ethyl alcohol on human subjects. WALTER R. MILES. *Carnegie Inst. Washington Pub.* 333, 308 pages (1924).—Administration of alc. in doses of 21 to 37.5 g. abs. alc. and in concns. between 2.75% and 22% produced the following effects. The pulse rate during rest and during work, the metabolism (O_2 consumption), temp. of skin of face and of hands, and swaying of the body were increased; the amplitude of the patellar reflex and of the lid reflex were decreased; the latency of the lid reflex, the eye-reaction time, the word-reaction time, the finger-movement speed, and the velocity of eye-movement (both adductive and abductive) became slower; the visual acuity and the elec. threshold sensitivity became less keen; the coordination for the pursuit pendulum and for the pursuit-meter became less adequate; in typewriting, the strokes per sec. were decreased, while the errors and illegibility were increased; the trans-literation of letters in code was decreased. "There is no longer room for doubt in reference to the toxic action of alcoholic beverages as weak as 2.75% by wt. If 27.5 g. of alc. are taken in this form, the well-defined and measurable depression in physical and mental processes is not far short of the result found when 21 to 28 g. of alc. are taken in solns. varying from 14 to 22%. Alcoholic beverages of all strengths may be taken so slowly, in such small amts. or so dild. with food that the content in the blood remains very low and the effects likewise remain minimal." Clearly recognizable char-

acteristic subjective symptoms appeared when 25 g. or more of alc. were dild. to a concn. of 14 to 22% and administered on a relatively empty stomach. Noticeable subjective symptoms also appeared in a majority of the subjects when 27.5 g. of alc. were mixed in 1 l. of dild. grape juice, then ingested; the symptoms were most marked during the first 35 to 40 min. after complete ingestion, and most noticeable on rising, standing, or walking.

Nitrous oxide-acetylene-oxygen, the ideal general anesthetic for extraction of teeth and oral surgery. AARON GOLDMAN AND J. D. GOLDMAN. *Dental Cosmos* 67, 969-79(1925).—An elaborate discussion and description of the use of a mixt. of N_2O , C_2H_2 , and O_2 for the production of general anesthesia.

Nitrous oxide-oxygen: a review of some of the factors contributing to its successful administration. T. C. BONNEY. *Dental Cosmos* 67, 1093-6(1925).—A review.

Atropine and tropine. Effect of the tropine base on the vagus. RENÉ HAZARD. *Compt. rend. soc. biol.* 93, 515-7(1925).—Injections of either the free tropine or of its salts causes a diminution of elec. excitability or even a complete loss of the vagus. Similarly, an injection of adrenaline preceding an injection of tropine has the same effect as when atropine is used, namely, a regular rise in blood pressure, a transitory acceleration of the heart and a suppression of extrasystoles which adrenaline produces through its vagus action. The effect of the 2 drugs is therefore the same.

Intravenous silver therapy. II. Effect of the electrolytes of the body on the solubility of silver salts. K. V. NEERGAARD. *Arch. exptl. Path. Pharm.* 107, 316-48(1925).—The inorg. ions normally present in physiol. concn. other than the Cl ions have no material effect upon the concn. of Ag ions which can be reached in the body. The highest possible concn. of Ag ions is about $1/10,000$ mg. per l. The max. concn. to be attained is reduced by the administration of Br and I salts, and in pathol. conditions the presence of ionized S may very greatly reduce the physiol. max. concn. of Ag. Complex Na-Ag salts are formed in media contg. the physiol. electrolytes, and here again the satn. concn. is primarily detd. by the Cl ions. The max. concn. of the complex salts is approx. 1 mg. per l. In ordinary therapeutic procedures the satn. concn. of Ag is not reached. The reactions which govern the formation of AgCl and of complex Ag salts are intimately related, to the end of maintaining an equil.

Nervous control of secretion by the kidneys. I. AD. M. BROGSITTER AND WILH. DREYFUSS. *Arch. exptl. Path. Pharm.* 107, 349-70(1925).—The functional activities of the normal kidney are modified by atropine to a greater extent than are those of a damaged kidney. Water elimination and the excretion of NaCl, creatinine and uric acid are inhibited. Whether there is an elective action as regards functional changes is open to question. **II.** *Ibid* 371-83.—Sugar excretion in phlorhizin diabetes is inhibited by atropine, a paralysis of the parasympathetic nerve endings of the kidney. Pilocarpine very markedly stimulates the excretion, a vagus effect.

The effect of sodium arsenite on the blood sugar concentration of the rabbit and dog. II. B. VAN DYKE. *J. Pharmacol.* 26, 287-96(1925).— $NaAsO_2$ intravenously administered in doses considerably below lethal causes a distinct but variable hyperglucemia in the rabbit. Accompanying this hyperglucemia there is a reduction in the blood alk. reserve; there is no significant alteration in blood concn. as indicated by detns. of corpuscle volume or % of hemoglobin. The hyperglucemia still appears after bilateral splanchnotomy or right splanchnotomy and left adrenalectomy. $NaAsO_2$ therefore acts peripherally, in all probability by increasing hepatic glycogenolysis. The hyperglucemia may be checked or prevented by insulin. Intravenous injections of $NaAsO_2$ in the dog cause a reduction in whole blood alk. reserve, often with a slight hyperglucemia.

Skin absorption of certain gases. D. C. WALTON AND M. G. WITHERSPOON. *J. Pharmacol.* 26, 315-24(1925).—HCN gas is absorbed by the skin of dogs and guinea pigs; whether or not the outcome is fatal depends upon the concn. of the gas. H_2S is absorbed by the skin of guinea pigs but it is only lethal when large areas of the skin are exposed to the pure gas. CO does not appear to be absorbed by the skin.

I—ZOOLOGY

R. A. GORTNER

The influence of certain factors in the development of the flagellum Prowazekia (Bodo) edax. H. RAAHE. *Bull. soc. chim. biol.* 7, 842-59(1925); cf. C. A. 19, 2375. The initial intensity of development is greater the less the depth of water. Multiplication with normal development takes place most intensely where there is neither excess

nor lack of nourishment. The limit of acidity is p_{H} 4.8. Flagella will develop at an alk. of at least 9.6. A. T. CAMERON

The excretion of water and of gas by frogs submerged in water. A. T. CAMERON AND D. R. McCULLAGH. *Trans. Roy. Soc. Can.* 19, Sect. V, 99-106(1925).—The urine secretion of frogs submerged in water is normal, and is largely governed by temp. The O_2 requirement of the submerged frog is met by gaseous diffusion through its skin, which does not involve passage of water across the skin. The submerged frog liberates a small amt. of gas, chiefly N_2 ; this liberation seems to be to some extent a function of total solid surface in contact with an aq. soln. A. T. CAMERON

Digestion of cellulose by invertebrates. C. M. YONGE. *Science Progress* 20, 242-8(1925).—A comprehensive review with references to the original literature. JOSEPH S. HEPBURN

Study in the nutrition of an invertebrate, *Planaria maculata*. ROSALIND WULZEN. *Univ. Calif. Pub. Physiol.* 5, 175-87(1923). On certain diets (either starch paste or gelatin flavored with liver juice, raw egg yolk plus starch or sugar, raw egg albumin, beef fat) planarian worms decreased in size although sufficient food for growth apparently was ingested. Other diets (raw egg yolk, thyroid, muscle and white matter of the brain) maintained the worms in their original condition and even produced growth to a slight degree. Still other foods (liver, thymus, adrenal, kidney, pineal and gray matter of brain) produced rapid growth and fission. Since planarian worms are perceptibly sensitive to minute variations in the chem. compn of their diet, they are excellent subjects for nutrition expts. JOSEPH S. HEPBURN

12—FOODS

W. D. BIGELOW AND A. E. STEVENSON

The development of modern food chemistry. A. BEYTHILN. *Z. Nahr. Genussm.* 50, 14-21(1925).—An address. WILLIAM J. HUSA

The development and problems of the association of German food chemists. J. KÖNIG. *Z. Nahr. Genussm.* 50, 8-13(1925).—An address. WILLIAM J. HUSA

The mineral value of foods. RAGNAR BERG. *Z. Nahr. Genussm.* 49, 378-80(1925).—A reply to the criticism of Pfyl (*C. A.* 19, 682). B. PFYL. *Ibid.* 381 2.---Answer to Berg. WILLIAM J. HUSA

The control of foods eaten raw. H. N. BUNDLES. *J. Am. Med. Assoc.* 85, 1285-9(1925).—This address gives a history of the development of modern food control as applied to dairy products, shell fish, fruits, vegetables, carbonated beverages, raw meat and sausage. L. W. RIGGS

Study of the gases in canned foods. RAY WM. CLOUGH, O. E. SHOSTROM AND E. D. CLARK. *Univ. of Washington Publications in Fisheries* 1, 86-98(1925).—An app. for measuring the vacuum or pressure in a can of food, drawing the gases from the headspace in the can, and analyzing them, is described. The av. daily phys., chem. and bacteriological decompn. changes in 5 species of Pacific Coast salmon, canned at 24-hour intervals during a 6-day period of decompn., are tabulated. Relation between odor and % CO_2 and H_2 in the gases of headspace of the exptl. pack and also of comp. packs is tabulated. In general, as the odor of decompn. becomes more pronounced the CO_2 in the gases increases, and when there is over 20% CO_2 the product usually has a stale or tainted odor. Presence of H_2 indicates considerable decompn. has taken place; but its absence does not indicate absence of decompn. A. P. C.

Presence of indole in sea foods and other food products. RAY WM. CLOUGH, O. E. SHOSTROM AND E. D. CLARK. *Univ. of Washington Publications in Fisheries* 1, 103-8(1925); cf. Clough, *C. A.* 17, 3550.—Examination of 68 samples representing 35 different products from 66 sources showed 0.5-1.5 mg. of indole per 100 g. in 9 samples, 2.5-15 mg. in 9 samples, and 20-5000 mg. in 11 samples. No skatole was found in any of the samples. Unsatisfactory color tests were obtained from all samples which had been heavily spiced. Indole seems to be a normal constituent of some cheeses, e. g., Camembert, Camembert and Limburger. Its presence in the other cheeses in much smaller amounts indicates that it is not a normal constituent, and in some cases where it was found the cheese was clearly abnormal. Its presence in other products may be safely taken as evidence of some degree of decompn. A. PAPINEAU COUTURE

Metallic compounds in foods. M. WAGENAAR. *Pharm. Weekblad* 62, 1109 1st (1925), cf. *C. A.* 19, 2378. —The fate of metallic salts when added to food products, and the org. matter then destroyed by the $\text{H}_2\text{SO}_4\text{-HNO}_3$ method, was detd. in the

case of Sn, Sb, As, Pb, Cu, Bi, Cd, Hg and Zn. Of these, Hg was the only metal which showed any noteworthy loss due to volatilization.

A. W. DOX

Report on (the determination and identification of some) coloring matters in foods. C. F. JABLONSKI. *J. Assoc. Official Agr. Chem.* **8**, 622-6(1925).—To differentiate *guinea green B* (S. & J. No. 433) (I) from *light green SF yellowish* (S. & J. No. 435) (II) it is ordinarily sufficient to ext. a neutral aq. soln. of the dye contg. about 5% NaCl with an equal portion of AmOH, which will remove most of I and only traces of II. For quant. sepn. of the dyes ext. a HCl soln. of the dyes with AmOH and wash the AmOH ext. several times with an equal vol. of a soln. contg. NaCl 250 g., Na acetate 27.2 g., AcOH 24 cc., H₂O to 1 l.; II is extd. by the NaCl-NaOAc soln. and I remains in the AmOH. *Orange I* (S. & J. No. 85) (III), if present, will remain in the AmOH and interfere with I. To sep. the two, ext. the aq. soln. of I and III with several small portions of washed dichlorohydrin which removes all I and some III; remove III by shaking the combined dichlorohydrin exts. first with H₂O and then with NH₃ aq. (1 + 27) till the washings are colorless, and then again with H₂O; finally, dil. the dichlorohydrin with 5 vol. CCl₄ and shake with 25% alc. to remove I. *Yellow AB* (benzocazo- β -naphthylamine) (IV) and *Yellow OB* (o-toluenazo- β -naphthylamine) (V) in alc. soln. give a red coloration with strong HCl. On shaking a 0.001% gasoline soln. of the dye with an equal vol. of a mixt. of 1 part of 40% CH₂O and 4 parts Ac₂O, the dye is extd. by the Ac₂O, IV giving a red soln. and V an orange one. On treating an alc. soln. of the dye with an equal vol. of 84% aq. soln. of citric acid, IV gradually turns rose-red, and V is gradually decolorized. A method for the quant. sepn. of the two is described in detail and consists essentially in extg. IV from the gasoline soln. of the 2 dyes by means of 15% alc. by vol. contg. enough H₂SO₄ to make a 10 N soln., immediately making the alc.-H₂SO₄ soln. alk., and extg. IV by means of Et₂O. The gasoline soln. of V and Et₂O soln. of IV are evapd. to dryness at low temp. (the dyes are somewhat volatile), the residues taken up with 95% EtOH and compared colorimetrically with standard solns. (about 0.001% of the dyes). The quantity of V washed out by the acid is approx. equiv. to the quantity of IV retained by the petroleic ether. To check the detn. of IV dil. the original color soln. to a definite vol., use exactly half for extn., compare the V obtained with the original soln., IV being the difference between the two.

A. PAPINEAU-COUTURE

Collaborative study of moisture methods. G. A. SHUEY. *Cereal Chemistry* **2**, 318-23(1925). The vacuum method (a) of detg. moisture which consists of heating approx. 2 g. accurately weighed in a vacuum oven at 98-100° for 5 hrs. at a pressure not more than 25 mm. Hg was compared with the following routine methods: (b) approx. 2 g. accurately weighed are heated in an air oven at 130° for 1 hr.; (c) same as b except that the temp. was 125°; (d) same as b except that the temp. was 135°. The dishes used for samples were cylindrical Al. 18 mm. high and 60 mm. in diam. with closely fitting covers. During the heating the covers were removed. After drying the dishes were covered tightly and placed in an efficient desiccator, preferably one in which CaC₂ or freshly ignited CaO was used as desiccating agent. The mean of all averaged results from each of the 4 methods studied are as follows: Vacuum 13.38%, (b) 13.25%, (c) 13.218%, (d) 13.306%. Methods b and c compare most favorably with the vacuum method. Data obtained by S. justifies a further study with view to adoption of routine method as a rapid and quick one for mill labs.

RUTH BUCHANAN

Gasometric calcium carbide method for the determination of moisture. W. A. JAKOWENKO. *Z. Nahr. Genussm.* **49**, 360-70(1925). The moisture in bread, flour and other materials was detd. by the gasometric CaC₂ method. In the case of vegetable substances the C₂H₂ was evolved rapidly at first, then at a constantly decreasing rate, while in the case of crust hydrates the rate was const. J. concludes that in amorphous vegetable substances moisture is held in the form of absorption compds.

W. J. H.

Report on (the determination of moisture in) wheat flour. G. C. SPENCER. *J. Assoc. Official Agr. Chem.* **8**, 667-70(1925), cf. C. A. **19**, 1315. Two methods are recommended: a standard or referee method consisting in drying 2 g. to const. wt. (about 5 hrs.) at 98-100° at an abs. pressure of not over 25 mm.; and a routine method consisting in heating 2 g. for 1 hr. at 130° at atm. pressure. Collaborative work showed that the 2 methods give concordant results.

A. PAPINEAU-COUTURE

Note on weight losses of bread. C. B. MORISON AND L. P. GREBER. *Baking Tech.* **4**, 304-6(1925).—The initial moisture content of bread made under known conditions was taken 1 hour after baking and then the bread was exposed on a shelf in the lab. permitting free ventilation and weighed at approx. 24-hour intervals for 40 days. From the 16th day the moisture shows only slight deviations according to general

atmospheric conditions. The moisture content of the bread at the 16th day as calcd. from the initial moisture content and weight of the bread 1 hour after baking and the loss in weight for 16 days ranged from 9.2 to 11.3%.

RUTH BUCHANAN

(Determination of) glutenin in flour. P. F. SHARP. *J. Assoc. Official Agr. Chem.* 8, 678-9(1925).—Preliminary work on the extn. of other proteins from flour by various solvents, preliminary to detg. glutenin, gave the following results: boiling with 0-100% EtOH for 1 hr. under a reflux condenser removed more protein than shaking mechanically for 1 hr.; 5% K_2SO_4 , KCl, $MgSO_4$ and $CuSO_4$ on shaking mechanically for 1 hr. removed more protein than 10% solns. of the same salts; 10% $MgCl_2$ removed more protein than 5% soln.; $MgCl_2$ removed nearly twice as much protein as the other salts used; H_2O removed more protein than any of the salts except $MgCl_2$; the amount of protein extd. by 70% alc. from the residues from the salt extns. was slightly affected by the nature of the salts, but considerably decreased in the case of $CuSO_4$. The results would require confirmation on other flours.

A. PAPINEAU-COUTURE

Report on sampling of flour. G. J. MORTON. *J. Assoc. Official Agr. Chem.* 8, 680-6(1925).—From the results of exptl. work which is described, M. recommends the following method of sampling: draw by means of a suitable trier inserted with light pressure and slow rotation through the middle of the top of the sack (placed in a horizontal position) a core of uniform diameter and from a depth approx. equal to the distance from the edge to the center of the sack; sample at least 10 sacks from 100, 15 from 300, 20 from 600, 30 from 1000; place the composite sample immediately in air-tight containers without mixing; prep. the sample by passing the flour 3 times through a domestic flour sifter, no further mixing being necessary. The trier devised for this purpose is made of heavy sheet Cu, and measures 12 in. long by 1 in. in diameter at the forward end and 1.75 in. at the rear end, and bears marks indicating the different depths.

A. PAPINEAU-COUTURE

Report on (the determination of) chlorine in bleached flour. ARMIN SEIDENBERG. *J. Assoc. Official Agr. Chem.* 8, 676-8(1925).—The Cl in bleached flour is commonly thought to be found in or with the fat. The following modification of Hertwig's neutral extn. methods for lipoids (*C. A.* 17, 3386) was found to give the most complete extn. without formation of emulsions: to 10 g. of flour in a 500-cc. Erlenmeyer flask add 30 cc. of 70% alc., warm very slightly till the flour is evenly distributed throughout the liquid, add 30 cc. of 95% alc., shake thoroughly for 2 min., add 100 cc. of petroleic ether (b. 30-75°), shake, transfer to a sepg. funnel, wash the contents of the flask with 2 25-cc. portions of petroleic ether and transfer to the sepg. funnel, add 30 cc. of water in the funnel, shake, draw off the lower layer, wash (if necessary) with only 10 cc. H_2O , draw off the lower layer, and evap. the petroleic ether at low temp. after addn. of 5 cc. of 4% alcoholic KOH.

A. PAPINEAU-COUTURE

A theory of colloid behavior in dough. C. O. SWANSON. *Cereal Chemistry* 2, 265-75(1925).—Dough is a mass of starch and protein particles covered by films of water. The surface tension forces inherent in these films of water bind the starch particles together as the particles of clay are held together and aid in holding the protein particles together. The colloid behavior is further explained on the assumption that the protein particles form chains or strands which have a rubbery elasticity and that these strands are matted together in a mass ordinarily known as gluten. The quality of the dough is detd. by the no. of particles present which form the strands, by their inherent structure and by the environment of particles. The number of particles are related to the quantity of protein in the flour and their structure to the quality, both being detd. when the wheat is formed. The manner of coherence among the particles and hence the quality of the gluten strands depends on the environment of the particles which consists mostly of water and substances dissolved in water such as sugar, enzymes, and electrolytes. Some of these substances affect the electrical condition and hence the binding force among the particles. Since the environment controls the condition of yeast growth and it is possible for the baker to modify the environment the qualities inherent in the colloid system may be modified to a limited extent.

R. BUCHANAN

Hydrogen peroxide and viscosity. R. K. DURHAM. *Cereal Chem.* 2, 297-305(1925).—The object was to det. if possible the extent of increase in absorption measured as hydration capacity by means of the relative viscosity of flour or wheat in water suspensions. Twenty g. of flour (13.5% moisture bases) and 100 cc. distd. water were mixed so as to break up lumps and yet cause as little foaming as possible, and then 2 cc. of lactic acid was added, the mixt. being stirred for 30 sec. The viscosity was taken by a MacMichael viscometer with a disk bob, No. 30 wire and rotating base 20 r. p. m. To this suspension a drop of 3% H_2O_2 was added and the viscosity again taken. It is shown that H_2O_2 produces increased hydration capacity of flour or wheat meal and

water suspension as thus detd. The investigation further revealed that flour grade and type of wheat are concerned with viscosity. There seems to be little relation between the hardness of wheat and its increase in viscosity with H_2O_2 (excluding durum wheat). Middling flours show greater increase in viscosity than do lower grades. The substance affected by H_2O_2 is shown to be sol. in water. Inferior milling produces a flour which shows a low increase in viscosity with H_2O_2 . RUTH BUCHANAN

Para rubberseed cake. ANON. *Fertilizer, Feeding-Stuffs, and Farm Supplies J.* 10, 14(1925).—A sample of Para rubberseed cake contained H_2O 8.75, crude protein 30.19, other N compds. 5.34, oil 8.71, starch 41.74, fiber 5.01, and ash 5.60%, nutrient ratio 1:2 and food units 139. The compn. of this material closely approximates that of linseed meal. K. D. JACOB

Report on (the sampling and analysis of) cereal foods. RAYMOND HERTWIG. *J. Assoc. Official Agr. Chem.* 8, 657-66(1925); cf. 5 preceding abstracts.—Results, reported above for sampling, detn. of H_2O , ash, glutenin, fat by acid hydrolysis, lipoids and lipid P_2O_5 , and detn. of Cl in bleached flour are briefly reviewed and discussed. The methods for H_2O (umpire vacuum method, and routine method at atm. pressure) and ash are recommended for adoption. R. also recommends adoption for the examn. of flour of the methods for fat (acid hydrolysis), lipoids and lipid P_2O_5 , and H_2O -sol. N precipitable by 40% alc at present incorporated in the official methods for alimentary pastes. A. PAPINEAU-COUTURE

Report on (the determination of) ash in cereal products. C. E. MANGELS. *J. Assoc. Official Agr. Chem.* 8, 671-5(1925); cf. *C. A.* 19, 543.—Collaborative results on ashing by ignition to a grey ash at 550° and by the Hertwig-Bailey method (*C. A.* 18, 2394) showed good agreement between the 2 methods. The latter gives results in less time, but requires either considerable attention to prevent frothing over or else the use of a large Pt dish or crucible. Addn. of $Ca(OAc)_2$ allows of igniting at a higher temp. without volatilization of the ash constituents, 20 mg. CaO (as $Ca(OAc)_2$) preventing fusion of the ash of both clear and patent flours at 1000° , with consequent reduction in the time required for ashing. A. PAPINEAU-COUTURE

Estimation of shells in cocoa. HEINR. FINCKE. *Pharm. Zentralhalle* 66, 565 7(1925).—A critique of the method of Weber and Bötticher. W. O. E.

Effect of low temperature on hen eggs. T. MORAN. *Proc. Roy. Soc. (London)* 98B, 436 56(1925).—After freezing and thawing, the white of an egg is sepd. into a fluid part and a viscous part; the increase of the former at the expense of the latter is governed by the abs. temp. attained and by the time of exposure to that temp. After freezing and thawing, the yolk loses its normal fluidity and becomes a stiff paste, provided freezing and storage occurred at a temp. below -6° ; a time factor is also concerned in this change; apparently lecitho-vitellin is pptd. on freezing and does not redissolve on warming. Permanent changes in vol. also take place. While no visible change occurs in eggs which have been supercooled to temps. as low as -11° , nevertheless an irreversible change actually takes place and gives rise to a decrease in vol. The effect of temps. between -4.6° and 16.2° on the fertile egg was also detd. Eggs rapidly lose their fertility at temps. below 0° and apparently the embryo of the egg dies immediately at approx. -6° to -7° . The optimum temp., at which fertile eggs retain their fertility for the longest period of time, lies in the region of 8° to 10° . J. S. H.

The determination of the content of volatile oils in spices. N. SCHOORL. *Chem. Weekblad* 22, 381(1925).—Steam distn at a slightly elevated temp. (108.8°), with its consequent advantage of more rapid recovery of the oil to be distd., may readily be accomplished by adding an excess of NaCl to the mixture to be distd., and proceeding as usual with steam at 100° . •• DONALD W. MACARDLE

The significance of specific conductivity in the analysis of milk. R. STROHECKER. *Nahr. Genussm.* 49, 342 52(1925); cf. *C. A.* 13, 2936.—The sp. cond. of normal mixed milk varied between 45 and 50×10^{-4} . The observed values for individual cows ran from 42.7 to 74.4×10^{-4} . Values above 50×10^{-4} indicate abnormal or diseased conditions. WILLIAM J. HUSA

The Rupp method for the detection of chlorine in milk. J. T. KEISTER. *Am. J. Pharm.* 97, 638-42(1925).—The Rupp test is not reliable when the milk contains more than 1 part of Cu in 400,000 parts. Fresh milk contains very much less Cu than 1 part in 400,000. It may, therefore, be assumed that the Rupp procedure is admissible for testing a fresh milk for Cl. In fact, in all the tests made on fresh milks including bottled market milks, the Rupp test gave negative results. Nevertheless, it is controllable that under certain conditions bottled milk might take up enough Cu to give a positive reaction with the Rupp test. It would seem, therefore, that in case a milk

gives the Rupp test, the Cu content of the milk should be established in order to avoid an erroneous conclusion as to the presence of added Cl. W. G. GAESSLER

The detection of raw whole milk in pasteurized skim milk. Investigation of the leucocyte count and catalase number of cupped and centrifuged cream. F. HERKMA. *Tijdschr. vergel. Geneeskunde* 11, 310-9(1925).—The detection of raw whole milk in pasteurized skim milk by means of the trypan blue leucocyte stain is too cumbersome for practical purposes. The leucocyte no. is higher in centrifuged (I) than in cupped (II) skim milk. The reverse is the case for the creams. Leucocytes seem to play a rôle in the coagulation of fat globules and spontaneous cream sepn. since I has a considerably greater agglutinating effect on washed fat globules than II. Similarly higher catalase nos. were associated with higher leucocyte counts. MARY JACOBSEN

Variations in, and constant relationships between, the quantity and fat content of milk from morning and evening milkings during different seasons of the year, and for different time periods between the milkings. J. STREMLER. *Rev. agr. Maurice* 2, 536-9(1925).—The quantity and fat content of milk for semi-monthly periods during an entire yr. are shown in 2 charts, and the following conclusions are drawn from the figures obtained: The greater the quantity of the milk, the smaller is its fat content. For this reason less butter is obtained in summer than in winter. The more time elapses between the 2 milkings, the more milk, but of less fat content, is obtained. For 12 hr. intervals there is no difference between the 2 milkings. F. W. ZERBAN

Preliminary investigations in the bacteriology of milk. J. H. WALTON. *Ag. Research Inst., Pusa, Bull.* 159, 14 pp (1925). The bacterial count of the milk supply from the Pusa exptl farm was compared with the English standards. Of 37 daily samples taken during the dry season, 35 contained less than 20,000 bacteria per cc., while during the wet season 23 samples out of 35 contained 20,000 to 100,000 per cc. *B. coli* contamination was also greater in the wet season. The fore milk contained from 3 to 24 times as many bacteria as the middle milk, and milk drawn into open pails contained 2 to 5 times as many bacteria as milk drawn into covered pails. The ratio of the final bacterial count to the initial count on milk stored for 4 hrs. at 10° was 2, and at 30° 8. For 20-hr. storage the ratios were 10° 3, 14° 10, and 30° 72,300. K. D. JACOB

Reinfection of pasteurized cream. I. From factory utensils. A. M. BROWN AND H. H. RANDELL. *Ag. Gaz. N S Wales* 36, 567-70(1925). Scrapings collected from the inside of churns just prior to running in the cream contained in one case 3,000,000 and in another 20,000,000 organisms per cc., two thirds of which were of undesirable types. Rinsing waters run out just prior to commencement of churning contained 1000 to 9,000,000 per cc., practically all of which were injurious types. Utensil rinse waters in which no lime was used contained 800,000 to 9,000,000 bacteria per cc. dependent on the procedure used in washing. Effective control methods are discussed. **II. From impure water.** O. C. BALLHAUSEN. *Ibid* 570-7.—Bacterial counts on H₂O filtered through different filter media were as follows: well water, felt filter changed once or twice per day, 100; creek water, paper pulp filter changed once per week or fortnight, 2000; creek water, candle filter changed once per week, 3000; river water, sand gravel filter, 100; river water, felt filter changed occasionally, 600 per cc. The counts were made on purified H₂O just prior to changing the filters. K. D. JACOB

Treatment of cream for the removal of objectionable flavors and odors. O. F. HUNZIKER. *J. Dairy Sci.* 8, 132-45(1925).—The treatment found most effective in removing off-flavors from cream for butter making consists of standardizing the cream to a reasonably low, definite point of acidity, flash pasteurizing it and spraying it into a high vacuum, then blowing heated air through a continuous spray of the hot cream while still maintaining a partial vacuum. The time of treatment varies from instantaneous to 15-30 min., and even longer, according to the type and intensity of flavor defect. To avoid premature churning and insure butter with a smooth texture free from meanness, the cream must be kept in motion until cooled, and cooled rapidly and without excessive agitation. The treatment is applicable only to volatile or volatilizable off-flavors. A. PAPINEAU-COUTURE

The effect of different percentages of butter fat on the physical properties of ice cream. D. H. NELSON AND H. E. REID. *Missouri Agr. Expt. Sta., Research Bull.* 70, 24 pp.(1924).—With each additional increment of 2% of fat to the mixt. the sp. gr. was uniformly decreased and the viscosity was increased. The overrun increased up to 10% of fat. Above 10% of fat, the overrun decreased although the viscosity continued to increase. No direct relation was found between the fat content of the different mixts. and the hardness of the ice cream. An increase in the fat retarded the melting.

of the ice cream by increasing the resistance offered to summer temps. Variations in the overrun had a decided effect on the stability of the finished product. J. J. S.

Preservatized and non-preservatized butter. ANON. *New Zealand J. Agr.* **31**, 157-8(1925).—The addn. of "boron compd." in amts. ranging from 0.08 to 0.90% had little effect in sustaining the keeping quality of butter either in cold storage or afterwards at room temps. In 7 expts. with butter from different sources the av. was slightly in favor of the preservatized butter. K. D. JACOB

Study of mixtures (of butter with other fats). M ZAAYER. *Chem. Weekblad* **22**, 461-4(1925).—Various analytical methods for the detn. of butter fat are described and their accuracy is compared by tests on known mixts. of butter, coconut- or palm-oil and tallow. The Bertram method (*C. A.* **18**, 556) is very accurate, but requires an inconveniently large sample (25 g.). The Epple and Spitzer method (*C. A.* **18**, 2772) gives inaccurate results. The Gilmour method (*C. A.* **19**, 2713) is accurate but unduly long. Van der Laan's modification (*C. A.* **17**, 2018) of the Kirschner method has been still further modified by van Raalte, giving a procedure which is more rapid, more accurate, and more convenient than any other here studied. For details of method, calcn., and correction for other fats present, the original paper must be consulted. In the analysis of 6 samples contg. 10-20% butter, 40-60% coconut- or palm-oil and 30-40% tallow, the max. error in the butter content was 0.4%. D. W. MACARDLE

Catawba grape juice. B. G. HARTMANN. *J. Assoc. Official Agr. Chem.* **8**, 716-25 (1925).—Analyses of 15 samples each of pasteurized and of sulfured typical com. juices of known purity prepd. from crops of several seasons are tabulated and commented. There is only a slight difference in the solids content of the juices obtained at various stages of the pressing; but the acidity of the free-run juice is appreciably lower than that of the final juice. Juices of different seasons vary, but those of the same season are very similar. There is considerable free tartaric acid and another free acid (probably malic). Low acidity together with low polarization at 870 would indicate watering (generally by addn. of a 20% sugar soln.). Tissier and Francois' method for detection of added water in wines (*C. A.* **8**, 3481) has been adapted to grape juice and the technic is described in detail (cf. following abstract). A. PAPINEAU-COUTURE

Report on (the analysis of) fruit and fruit products. B. G. HARTMANN. *J. Assoc. Official Agr. Chem.* **8**, 626-9(1925); cf. 2 following abstracts.—Wichmann's and Nelson's results are briefly reviewed. A method for detg. added water in white grape juice is described (in detail), and is essentially as follows: Add 1 g. of finely powdered K H tartrate to 50 cc. of filtered juice, shake 1 hr. in a mechanical shaker, and titrate 10 cc. of the treated filtered juice and 10 cc. of the original juice with standard NaOH. Then $x = [0.0188(b-a) - 0.095 - 0.025(T-25)] \cdot 0.006$ where x is the % added water, b and a the acidity of the treated and original juice, resp., in cc. of 0.1 N NaOH per 100 cc., and T the mean temp. before and after shaking. Com. juices show about 1-3% of added water by this method. The method is inapplicable to red grape juice. A. P. C.

Report on pectin in jams, jellies and preserves. (Determination of fruit ash and of total solids.) H. J. WICHMANN. *J. Assoc. Official Agr. Chem.* **8**, 629-37(1925), cf. *C. A.* **19**, 544. To det. fruit ash in a product contg. added P_2O_5 , ash in the presence of a known amt. of MgO (in excess), and subtract the sum of the total P_2O_5 (corrected for that contributed by the fruit present, best estimated from the water-insol. solids in the case of jams and preserves) and the MgO obtained in the blank. If glucose also is present, a further correction must be made, based on the av. ash in glucose solids (approx. 0.396%). Results given on various products indicate that the max. errors by this method are about ± 0.03 g. per 100 cc. of sample. Considerable difficulty may be experienced in obtaining a white ash, requiring extn. of the char with hot water and ashing the residue with repeated applications of HNO_3 . If alum has been added, ash as before with an excess of MgO, and subtract the MgO and anhydrous alum, which may be obtained from either Al_2O_3 (detd. as $AlPO_4$) or SO_3 in the ash (if glucose also is present allow for the SO_3 in the glucose ash). The order of accuracy for true fruit ash is about the same as in the case of added P_2O_5 . The drying method for detg. total solids in fruit products contg. sucrose and org. acids is shown to be unreliable because of the inversion of sucrose during the drying. Results are given which appear to indicate that the n method for total solids is preferable to the drying methods. A. P. C.

Report on (the determination of) fruit acids (in fruit and fruit products). E. K. NELSON. *J. Assoc. Official Agr. Chem.* **8**, 637-40(1925).—Detn. of malic acid in the presence of equal or greater quantities of citric and tartaric acids by the Auerbach method (*C. A.* **18**, 511,868) is inaccurate, only about 70% of the malic acid taken being recovered. Conversion of the acids into Ba salts by treating their alc. soln. with $BaCO_3$ failed entirely owing to the insoly. of the $BaCO_3$ in alc. soln. of the org. acids, and Ba

malate is incompletely sol. in H_2O in presence of Ba citrate and Ba tartrate. The official A. O. A. C. method for *tartaric acid*, a slight modification of the same (holding the soln. contg. the pptd. K H tartrate at a temp. of 20° instead of in the ice box), and the Kling method (*C. A.* 4, 1590; 6, 3382) were submitted to collaborative study under very severe conditions (the tartaric acid constituted only 10% of the total org. acids). Results by the official and modified official methods were widely divergent, mostly high, but in one case very low, probably due to the use of KCl that had an alk. reaction. The Kling method gave uniformly satisfactory results. A. P.-C.

Report on spices and other condiments. (Methods for the analysis of salad dressings.) R. E. ANDREW. *J. Assoc. Official Agr. Chem.* 8, 698-701 (1925).—Collaborative comparison of the present tentative A. O. A. C. method and of a proposed alk. extn. method (described in detail) for fat in salad dressing showed excellent agreement between the two. Collaborative comparison of the Juckenack method and of a proposed method for lipid P_2O_5 (add 5 cc. of 8% alcoholic KOH per g. of fat, evap. to dryness, char over asbestos, treat with dil. HNO_3 (1+2), filter, wash, burn the residue to a white ash, and det. P_2O_5 by the official method) showed lower results by the proposed method in most cases.

A. PAPINEAU-COUTURE

The influence of acidity on the formation of pectin compounds. ALFRED MEHLITZ. *Z. tech. biol.* 11, 134-54 (1925). The extn. of pectin from dried apple juice is carried out most satisfactorily with hot 0.02 N tartaric acid soln. as shown by a series of tests carried out with varying concns. from 0.001 N to 0.1 N. With greater acid concn. than 0.02 N the yield of pectin was decreased. Pectin exts. with a pH of at least 3.1 are well suited for jelly making. As a substitute for tartaric acid in the extn. of pectin only acids with approx. the same dissociation const. can be used such as malic, formic, salicylic and citric.

H. J. DEUEL, JR.

The use of pectin preparations in the manufacture of marmalades, jellies and similar fruit products. C. GRIEBEL AND M. NOTHNAGEL. *Z. Nahr. Genussm.* 49, 352-9 (1925).—A discussion of the compn. and use of com. pectin prepns., with tabulated analyses of 4 such prepns.

WILLIAM J. HUSA

Adulteration of marmalades. A. LABO. *Riv. ital. ess. profum.* 7, 137-9 (1924); 8 (Jan. 15, 1925); *Chimie et industrie* 14, 460 (1925).—A discussion of the commoner forms of adulteration and of their detection.

A. PAPINEAU-COUTURE

Dialysis of lemon juice. GUIDO AJON. *Riv. ital. ess. profum.; Perfumers' J.* 6, No. 9, 12-3, 56, 58 (1925).—See *C. A.* 19, 2865.

A. PAPINEAU-COUTURE

A new fodder (siloed shisham leaves) for dairy cows. P. E. LANDER AND P. L. C. DHARMANI. Agr. Research Inst., Pusa, *Bull.* 158, 11 pp (1925).—A sample of fresh shisham (*Dalbergia sissoo*) leaves contained H_2O 73.11, ash 5.14, fat 0.81, crude fiber 7.40, total N 0.69, protein N 0.57 and amide N 0.02%. A quantity of the fresh leaves was packed into a silo and samples of the material were analyzed at intervals during a period of 9 months. Volatile org. acids and volatile bases increased continuously during the storage period. Amino acids and amide N increased to a max. at 4-months storage and then decreased to approx. the original content. No appreciable change occurred in the other constituents. The siloed leaves had a pleasant aromatic smell, were greenish brown in color, and free from the mucilaginous substance which was particularly noticeable in the fresh leaves. The siloed material was substituted for all green food in the rations of two dairy cows for one month, two animals of approx. the same age and wt. being carried as checks. No deleterious effect was noted in the quality of the milk of the animals fed on the leaves, and the yield though somewhat smaller was fairly well maintained. The animals remained in perfectly good health throughout the test period. Siloed shisham leaves are considered by the authors to be a satisfactory reserve fodder in times of scarcity.

K. D. JACOB

The sunflower as a silage crop—composition and yield at different stages of maturity. W. L. GARNES AND W. B. NEVENS. Univ. of Illinois Agr. Expt. Sta., *Bull.* No. 268, 407-55 (1925).—Yields and chem. compns. of sunflower and corn crops are compared. Sunflowers produce greater yields of dry matter per acre than corn. They also contain more ash, crude fiber and crude fat but less N-free ext. It is desirable to ensile sunflowers at an earlier stage of growth than corn, since the crude fiber of the former more rapidly decreases in digestibility with advance in growth. The ash constituents removed from the soil by a sunflower crop are large, being about 900 lbs. per acre. Marked reductions in total ash of a crop occur toward the end of a growing season. The relative proportions of ash constituents and org. matter vary greatly at different stages of growth but the changes in relative proportions of ash constituents are small.

M. S. ANDERSON

Determination of fat in cacao products (LEPPER, WATERMAN) 27. Detection of coconut and palm kernel oils in cacao butter and fat from milk chocolate (Baughman) 27. Apparatus for disintegrating, emulsifying and mixing milk powder (U. S. pat. 16, 191) 1.

Food mixture. C. W. HOOPER. U. S. 1,557,053, Oct. 13. Finely divided desiccated animal liver, desiccated juice of oranges or other fruits and glucose or other "infant food carbohydrate" material are mixed with dry milk powder to form a food miscible with H_2O and for use in feeding infants.

Food containing rice and edible oils. C. DOERING and H. H. DOERING. U. S. 1,550,681, Aug. 25. Whole rice and ten times its quantity of H_2O are heated together under about 20 lbs. per sq. in. pressure at a temp. of about 120° and then the pressure is reduced while the mass is maintained at the b. p. A "rice milk" is sepd. by straining, agitated and aerated at a temp. of about 100° and allowed to cool. It may be mixed with coconut oil and animal "neutral oil" in the relative proportions 4:3:3 to form a butter substitute.

Food from fish. T. ENDO. U. S. 1,556,772, Oct. 13. Small lumps of flesh such as that of fish or shell fish are treated with a dil. acid soln. such as a 0.7% lactic acid or 0.5% H_2SO_4 soln., after H_2O and oil are squeezed out, and are mixed with cereal refuse, e. g., with parched rice bran or dried bean refuse, and the lumps are converted into "koji" in a hot house by covering them with spores of *Aspergillus oryzae*.

Bread. B. LOWY. U. S. 1,559,330, Oct. 27. Acid milk is mixed with Ca phosphate at 40° to produce a Ca lacto-phosphate, NH_4 tartrate is added, the compn. is mixed with yeast, salt, sugar and H_2O , and this aq. mixt. is used with flour to form a dough in the relative proportions of about 1:100, shortening is added and the dough ingredients are thoroughly mixed at a temp. of about 30° .

Milk substitute from soy beans. G. D. THEVENOT. U. S. 1,556,977, Oct. 13. The beans are ground, freed from husks, soaked in a mixt. of equal amts. of alc and H_2O , dried at a low temp., pulverized and mixed with sugar and salts such as those of Ca, Na or NH_4 to imitate the constituents of cow milk or form a compn. suitable for use in bread making, etc.

Hydrogen-ion concentration of flour. F. I. DUNLAP. U. S. 1,560,045, Nov. 3. In producing crackers, cookies or other bakery products, the shortening effect of the flour is increased by giving it an increased acidity up to about a p_H of 3, at about which point the "shortening" effect is at a max. The flour may be treated with Cl or HCl before use in the dough or the dough may be treated with HCl, H_3PO_4 , $HOAc$, lactic acid or other harmless acids.

Baking powder. R. E. JONES. U. S. 1,558,888, Oct. 27. A baking powder for conversion of some starch into sugar comprises Ca acid phosphate 5.25 oz., $NaHCO_3$ 3 oz., cornstarch 3.66 oz. and taka-diasatase 0.75 drachm.

Beverage extract. B. H. ZIEHLER. U. S. 1,557,917, Oct. 20. Exts. from malted cereal materials such as wheat, rye, corn or rice are heated partially to carbonize and caramelize the extractive material which they contain.

Fruit juices. W. S. PIERCE. U. S. 1,556,572, Oct. 6. The juice and pulp of oranges or other fruits are evapd. together *in vacuo* to a sirupy consistency. Sugar is impregnated with the essential oil of the fruit, this oil-impregnated sugar is added to the evapd. material and the evapn. is continued to obtain a dry product. The vacuum is broken at an intermediate stage of the drying in order to permit stirring of the material.

Preserving citrous fruits. H. R. FULTON and J. J. BOWMAN. U. S. 1,560,558, Nov. 10. A soln. of Li_2CO_3 is used for preventing decay.

Preventing decay of fruits and vegetables. H. R. FULTON and J. J. BOWMAN. U. S. 1,560,559, Nov. 10. A soln. prepd. from borax 5, H_2SO_4 0.43 and H_2O 100 parts is applied to citrous or other fruits or vegetables to retard development of stem-end rot, blue-mold rot, etc.

Apparatus for mixing and steam-treating fruit sauces, jams or other foods. W. A. SMITH. U. S. 1,556,365, Oct. 6.

Preventing decay of fruits and vegetables. H. R. FULTON and J. J. BOWMAN. U. S. 1,557,757, Oct. 20. The surface of citrous fruits or other fruits or vegetables is treated with a soln. of $LiOH$ or other alk. hydroxide. U. S. 1,557,758 specifies the similar use of a soln. of $LiCl$ or a similar compd.

Degasifying and steam-treating fruits for canning. F. G. GRAB. U. S. 1,557,358, Oct. 13.

Bleaching nuts. A. W. CHRISTIE. U. S. 1,558,963, Oct. 27. Walnuts or other

nuts are immersed in a soln. from which nascent Cl is being liberated and then in a soln. of SO_2 .

Apparatus for dehydrating fruits, etc. A. W. PARKER. U. S. 1,560,305, Nov. 3.

Apparatus for treating fruit with antiseptic solutions for preventing decay. W. R. BARGER, W. V. HUKILL and L. A. HAWKINS. U. S. 1,559,733, Nov. 3.

Apparatus for treating grain with powdered copper sulfate, copper carbonate, etc. A. J. BISHOP. U. S. 1,558,580, Oct. 27.

Preserving animal foods. G. SCHEIB. U. S. 1,557,779, Oct. 20. Whole carcasses of meat, fish or fowl, or smaller portions are treated with dil. HCl soln., CO_2 , N, or other gaseous or liquid preservative which is forced into the interior of the material under a pressure which is equal to or slightly greater than an external pressure which is maintained.

Treating green fodder. G. PFISTER. U. S. 1,551,427, Aug. 25. Green fodder is heated to kill bacteria detrimental to its nutritious substances and then superficially coated with HCl or with glue, dextrin, varnish or other material which will further restrict bacterial action and access of air.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Recent developments in the chemical industries of North Carolina. F. C. VILBRANDT. *J. Eliska Mitchell Sci. Soc.* **41**, 115-23(1925).—Recent statistics prepared by the Dept. of Ind. Chemistry of the Univ. of N. C. are analyzed. A. L. MEHRING

Engineering research: An essential factor in engineering education. C. E. MAGNUSSON. *J. Am. Inst. Elec. Eng.* **44**, 1243-5(1925). C. G. F.

A new departure in engineering education. HAROLD PENDER. *J. Am. Inst. Elec. Eng.* **44**, 1208-10(1925).—The Univ. of Pennsylvania has developed a new type of 4-year course. The first 2 years are spent in the academic dept. and the last 2 in the (chemical) engineering school. C. G. F.

Industrial development of electroosmotic processes. H. SARROT DU BELLAY. *Rev. prod. chim.* **28**, 649-55(1925), cf. Prydlender, *C. A.* **17**, 496.—A brief review of com. applications which have actually been effected and of recent progress. A. P.-C.

Utilization in the chemical industry of raw materials from sharks. RUDOLF TANDLER. *Chem.-Ztg.* **49**, 806-7(1925).—Although skins of marine animals were utilized during the World War, industry has not employed them successfully since that time. Yet sharks can be caught in immense numbers in tropical and semi-tropical seas, and if other parts of the carcass, e. g., liver, flesh, etc., are utilized as well as the skin, a remunerative industry can be maintained. Data are appended supporting this view. *Ibid* 841-2. Methods used for tanning the skins, packing the flesh, making stock food, fertilizers and oil are described. Suggestions are offered as to better methods for organizing the industry from the fisheries to the final markets. W. C. E.

Economic products from Dominica. ANON. *Bull. Imp. Inst.* **23**, 275-81(1925).—A sample of camphor was slightly discolored and contained a small quantity of oily impurity which rendered its aq. soln. slightly turbid; but otherwise its properties agreed well with those of a com. sample. Refined by sublimation, it would meet the requirements of the Brit. Pharmacopeia. A sample of ginger had consts. falling within the usual limits for com. ginger and agreed with those specified by the Brit. Pharmacopeia. A sample of crude gommier gum and 2 samples of prepd. gum ("incense gum") showed: loss on heating at 100° 6.78, 0.61, 0.43%; softens at 88° , 85° , 90° ; liquid at $115-20^\circ$, about 95° , $100-5^\circ$; acid value 34.0, 33.9, 33.8; sapon. value 70.8, 56.9, 56.9; ash 0.06, 0.09, 0.09%; completely sol. in EtOH, CHCl_3 , Et_2O , nearly completely sol. in turpentine oil, almost insol. in light petroleum. Cryst. from alc. gave a cryst. resin m. 181° (from crude gum) and 178° (from prepd. gum). For varnish making the crude gommier is of the same technical value as ordinary gum elemi, and the "incense gum" is inferior. Two samples of copra were found of good quality and contained normal amounts of oil of low acidity. A. PAPINEAU-COUTURE

(Solvent) recovery by the Brégeat system. RICHARD BLOCHMANN. *Chem.-Ztg.* **49**, 835-6(1925).—Cresol dissolves the solvent from the air by being brought into intimate contact with it in a closed system consisting of absorption towers acting on the countercurrent principle. The solvent is then expelled from the cresol by heating the mixt. in stage evaporators, and both cresol and recovered solvent are re-used. Initial recovery amounting to 90 or 95% gradually sinks, because of the increase in viscosity of

the cresol resulting from resinification. Keeping the app. clean becomes increasingly difficult. As possible improvements in present practice a lowering of the temp. from 140°, and a diminution of the number of times the cresol is reheated, are suggested.

W. C. EBAUGH

The recovery of volatile solvents. A. D. LUTTRINGER. *Caoutchouc and gutta-percha* 22, 12,627-9, 12,671-2, 12,858-60(1925).—A review of the industries employing volatile solvents, the physics of evapn. and condensation and typical equipment used in the rubber industry for recovering solvents such as benzene.

C. C. DAVIS

Another fatal poisoning by sodium fluosilicate. LÜHRIG. *Chem.-Ztg.* 49, 805-6 (1925).—A vigorous appeal for the recognition of F compds. as poisons from the legal point of view, and for the protection of workers and the public from them. In this, the fourth case, of F poisoning reported by the author, a man took 0.5 teaspoonful of insect powder in mistake for medicine, and in spite of medical aid died 10 hrs. later. The powder was 99.6% Na_2SiF_6 . Symptoms: diarrhea with vomiting, chills, inflammation of the mucous lining of the stomach, etc. Na_2SiF_6 was not found in blood or urine, but was detd. in samples of the alimentary canal and contents, kidneys and liver.

W. C. EBAUGH

Paralysis of the extensors of the hand as an early sign of lead poisoning, and a contribution to the prophylaxis of professional lead poisoning. W. HERGT. *Zentr. Gewerbehyg. u. Unfallverhüt.* [n. s.] 1, 37(1924); *Bul. mens. office internat. d'hyg. publ.* 17, 1036(1925).—H. has been unable to verify the claim of Toley that paralysis of the extensors of the hand is an early sign of lead poisoning although he has examd. hundreds of lead burners of the Badische Anilin und Soda Fabrik.

JACK J. HINMAN, JR.

Workshop and factory hygiene. III. Accident prevention and accident frequency. GEORG WOLFF. *Chem.-Ztg.* 49, 814-5(1925); cf. C. A. 19, 3555.—A comparative study of laws and statistics concerning accidents in industry, with the conclusion that efforts at accident prevention and medical care have brought about a great improvement in conditions for workers, and in savings for operators.

W. C. E.

Crystallizing various substances. H. HOWARD U. S. 1,559,703, Nov. 3. A suspension of crystals of the substance to be crystd. is maintained in an ascending current of a soln. of the material so that deposition from the soln. upon the crystals is induced. Crystals to be "grown" are supplied to the ascending current by introducing a relatively small stream of a supersatd. soln. of the substance into the current.

Removing suspended particles from materials forming viscous fusions. E. THOMSON. U. S. 1,559,203, Oct. 27. After fusing quartz or similar materials, the fusion is centrifuged to sep. suspended particles and then allowed to solidify so that the sepd. material can readily be sepd. mechanically from the solidified purified layer.

Controlling catalytic reactions. H. E. HAGGENMACHER. U. S. 1,557,687, Oct. 20. In order to control catalytic reactions and avoid or minimize side-reactions, fresh catalyst is continuously supplied and used catalyst is withdrawn after once falling through the reacting gases.

Absorbing vapors from gaseous mixtures. J. H. BRÉGRAT. U. S. 1,558,336, Oct. 20. Gas-vapor mixts. are subjected to the absorbing action of an absorbent liquid contg. a hydrogenated phenolic compd., e. g., hexahydrophenol or hexahydrocresol.

Heat insulation for pipes, boilers, etc. A. M. EHRET. U. S. 1,559,564, Nov. 3. Heat insulation formed of MgCO_3 and asbestos fibers is treated with a soln. of $\text{Mg}(\text{HCO}_3)_2$ in order to improve its strength and temp.-resisting properties.

14--WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Short history of the Keighley (England) Water Works. M. R. BARNETT. *Water and Water Eng.* 27, 345-9(1925).—The original supply from wells or springs established in 1816 was superseded in 1891 by slow sand filtered system. Water is treated with Na_2CO_3 before filtration to reduce plumbosolvency and after passing through slow sand filters passes through beds of polarite. Illus.

JACK J. HINMAN, JR.

The water supply of the city of Aberdeen. GEORGE MITCHELL. *Water and Water Eng.* 27, 56(1925); cf. C. A. 19, 1317.—The old works 20 miles west of the city is described. The new scheme authorized for the water supply in 1916 is based on 40 imp. gals. per day per person for a population of 240,000. It consists of a screen and intake chamber leading to a 60" conduit and a new 24 mg. concrete storage reservoir. There are 3 new filters

of a total area of 14 acres arranged to be cleaned by squeegeeing instead of scraping. The water of the Dee is very clear. JACK J. HINMAN, JR.

Supervision over the safety of Chicago's water supply. A. E. GORMAN. *Proc. Illinois Eng. Soc.* 40, 57-63(1925); cf. *C. A.* 19, 1319, 2097.—Water is obtained through 6 cribs in Lake Michigan 2 to 4 miles from shore. Calumet River is the chief source of contamination. Backing up of the Chicago River is an occasional menace. Dumping of dredged materials into the lake for fill and sewage from lake vessels are also important. Hourly tests for free Cl are made to check the adequacy of treatment at each station. 3000 lbs. liquid Cl are applied to 800 million gal. on the av. JACK J. HINMAN, JR.

Filters for Chicago's water supply. ANON. *Public Works* 56, 293-4(1925).—A general description is given of the proposed filtration plants projecting into Lake Michigan. C. C. RUCHHOFF

New gravity water supply for Whitehall, N. Y. JAS. P. WELLS. *Eng. News-Rec.* 95, 344-5(1925).—The new 3-m.g.d. supply of soft and bacteriologically satisfactory water from Pike Brook and Pine Lake, replacing the supply from the Metawee River which was moderately hard and at times unsatisfactory in quality, is described briefly. R. E. THOMPSON

Supplying of drinking water to vessels in the U. S. J. I. CONNOLLY AND A. E. GORMAN. *Public Health Reports* 40, 1042-55(1925).—Water supplies for U. S. vessels are obtained from (1) sources ashore and (2) from overboard. One system is provided on the ships for drinking water and one for water used for fire, boiler and cleaning purposes. If taken from ashore, sanitary precautions are confined to the purity of the source and methods of loading. If taken from overboard the water is usually treated by distn., ultra-violet rays, ozone or hypochlorites. Thirty-three vessels on the Great Lakes use ultra-violet ray treatment. Typhoid among seamen dropped from 150 per year in 1905 to 20 per year in 1924. Continued pollution of inland waters make close inspection necessary. Several cuts are shown of water connections, fountains and loading devices. BEN H. PETERSON

Great Lakes passenger vessels have pure drinking water. A. E. GORMAN. *Nations Health* 7, 604-5(1925).—A description of the ultra-violet ray sterilizers, chlorometers and ozonators used on Great Lakes steamers. BEN H. PETERSON

Primary filtration for municipal water supply. J. A. BERNARD. *Technique sanitaire* 20, 25-6(1925); *Water and Water Eng.* 27, 162(1925).—Details of the St. Denis plant. Water is taken from St. Denis River. The settling basin has 4 compartments each: inlet, discharge channel, 2 Cu screens, drain and opening and closing mechanism. Water enters the base of the filters and passes upward to the service tank and thence to the mains. JACK J. HINMAN, JR.

The "Guta" automatic chemical control apparatus. E. DEPLANTADE. *Technique sanitaire* 20, 106-10(1925).—Control of chemical feed is effected by varying the head on an orifice connected by a tube to a soln. reservoir. Control of the height is accomplished by a float connected to the orifice tube by a cord carried over a pulley or by a counterpoised vessel contg. a variable quantity of water. The rate of flow of the water supply detcs. the height of liquid in the float chamber or counterpoised vessel. J. J. H. JR.

Surface tension as a factor in the priming of steam boilers. E. B. MILLARD AND T. E. MATSON. *Ind. Eng. Chem.* 17, 685-6(1925).—No connection exists between surface tension and priming of boiler waters. JACK J. HINMAN, JR.

Observations on the working of slow sand filters. V. GOVINDA RAU. *Water and Water Eng.* 27, 350-2(1925).—The custom of wasting water from maturing filters is very wasteful since the water could be chlorinated and used. Re-sanded beds which give bad water for a time after re-sanding could receive chlorinated raw water and the effluent could be used. There is no deterioration of quality of effluent with high loss of head provided violent fluctuation of rate of filtration does not occur. In Bengal filter life is too short (2-6 weeks). Chlorination of raw water and suppression of algae should prolong use. Filters usually operate much more slowly than necessary. A drop of 2" per hr. was noted when 4" would have been better. Wasteful regulation of settling basins is common. Chlorination of raw water applied to slow sand filters is to be preferred to chlorination of filtered water. JACK J. HINMAN, JR.

River pollution. F. A. B. PRESTON. *Surveyor* 68, 101-2(1925).—The existing laws (England) with the unstandardized condition of chem. indices of pollution make it difficult to prevent pollution of streams by trade wastes. R. E. GREENFIELD

Is stream pollution necessary? C. M. BAKER. *Proc. Eng. Soc. Wisc.* 17, 77-84(1925).—It is not feasible to do away with stream pollution entirely under present

civic and industrial conditions, but it should be controlled and kept within reasonable limits.

Methods and policies of preventing stream pollution. H. V. PEDERSON. *Munic. and County Eng.* 68, 133-5 (1925).—The stream pollution situation in Iowa is discussed and a conservative policy in the prevention of stream pollution is advised.

Determination of minute amounts of phenols in polluted natural waters. J. R. VORCE. *Ind. Eng. Chem.* 17, 751 (1925).—Two or 3 l. of water are freed as well as possible from Ca, Mg, etc., by treatment with NaOH and filtration. H_2O_2 free from compds with benzene nucleus is added and allowed to stand overnight. The resulting soln. is then concd. to 200 cc. in strong alk. condition. This soln. is then made acid by addn. of citric acid crystals and distd. In the distillate the phenol is detd. colorimetrically by the use of the Folin and Denis phenol reagent.

Work accomplished by the Milwaukee Metropolitan Sewerage Commission. WM. R. COPELAND. *Proc. Eng. Soc. Wis.* 17, 71-2 (1925).

Activated-sludge sewage-disposal plant at Milwaukee. J. A. WILSON. *Mech. Eng.* 47, 837-41 (1925), cf. *C. A.* 19, 1465, 2251.—The sewage disposal plant is being completed. It contains coarse screens, fine screens and an activated sludge plant, using compressed air. The disposal of 1,275,000 gals. of waste activated sludge produced daily is a most serious proposition. It has been shown that the addn. of H_2SO_4 or $Al_2(SO_4)_3$, or heating, or combinations, greatly increased the efficiency of filtering processes, so that the sludge can be dried and prepd. for use in fertilizers.

Methods of sewage purification, activated sludge or bio-aeration process. F. W. HARRIS. *Surveyor* 68, 197-8 (1925).—A review.

Purification of sewage in France. F. DIENERT. *Technique sanitaire* 20, 153-4 (1925). A reply to Bezault (cf. following abstr.). D insists that knowledge of the character of the particular sewage to be treated in each case and other local features must be taken into consideration.

Sewage purification in France during the last 25 years. BEZAULT. *Technique sanitaire* 20, 132-7 (1925).

Columbus sewage disposal. ANON. *Public Works* 56, 359 (1925).—Chemical results, operating data and costs for 1924 are given.

Hydrogen ion concentration and p_H . L. H. ENSLOW. *Public Works* 56, 361-6 (1925).—A general description of the significance of p_H and its role in practical filter plant operation.

Normalcy in chemical treatment of sewage. J. F. JACKSON. *Public Works* 56, 379-82 (1925).—J. presents the results of the following methods of sewage treatment which he tried at New Britain and South Manchester. (1) Miles acid treatment followed by aeration with activated sludge; (2) Miles acid effluent neutralized and aerated with activated sludge; (3) saltpeter treatment followed by aeration with activated sludge; (4) lime treatment followed by aeration with activated sludge; (5) straight activation. None of these methods produced as good results as the straight bio-processes. Expts. with heat and acid treatment of sludge reduced the moisture content from 99.55 to 88.2% and demonstrated that even greater reductions were possible with well designed units.

Sewage treatment at Newark, England. ANON. *Public Works* 56, 316-7 (1925).—The plant with a capacity of 250,000 gals. per day has 5 pairs of 18 foot square Dortmund tanks in series. The first two pairs of tanks are used for preliminary settling, the third pair for activation and the last two pairs for final settling. The mixing and aeration chambers are fitted with revolving scoops which dip an inch under the surface.

Sewerage plans for New Jersey municipalities. ANON. *Public Works* 56, 318-9, 341-5 (1925).—Changes in the rules and regulations of the State Dept. of Health governing the prepn. and submission of plans for sewerage and sewage treatment plants are given.

Syracuse sewage treatment works. ANON. *Public Works* 56, 241-6 (1925).—The plant has a capacity of 27 million gals. of sewage per day and includes a grit chamber, mechanically cleaned fine screens, a sewage pumping station and 4 Dorr settling tanks. The effluent from the settling tanks is discharged into a lake and the sludge is pumped through a 12,000 ft. force main to a lagoon.

Data from state health boards. ANON. *Public Works* 56, 253-64, 297-306, 341-7 (1925).—Sewerage statistics and data on sewage disposal plants for cities in the U. S. are tabulated.

Sewage treatment in West Virginia. ANON. *Public Works* 56, 290-2 (1925).—

The treatment plant at Martinsburg with a capacity of 500,000 gals. per day includes an Imhoff tank, two sludge drying beds, sprinkling filters and two secondary settling tanks. The plants at Weston and Bluefield for treating the sewage from 1200 and 3000 persons, resp., are described.

C. C. RUCHHOFF

Sewage plant operation in Wisconsin. CHAS. I. CORP. *Proc. Eng. Soc. Wisc.* **17**, 63-6(1925).—Details of examples of difficulty with small plants due to neglect and operation by inexperienced persons

JACK J. HINMAN, JR.

Novel sewage disposal plant at Johnson Creek, Wis. W. G. KERCHOFFER. *Munic. and County Eng.* **68**, 188-9(1925).—The plant consists of 2 Imhoff tanks in series with an air lift pump in each tank to circulate the sludge. The air lift pumps are run 3 times per hour 5 min. at a time. The pump in the first tank discharges into a manhole about 50 feet in front of the plant and the one in the second tank discharges into the central cone of the first tank.

C. C. RUCHHOFF

Objectives in sewage treatment. J. J. HINMAN, JR. *Munic. and County Eng.* **68**, 167-72(1925).—The objectives which are legal and the actual improvement of the phys., chem., and bacterial state of the waste bearing liquors are discussed in a general way. The following objections to water pollution are discussed: (1) the nuisance of objectionable odors; (2) the possibility of contamination of water supplies; (3) the possibility of the steam being rendered dangerous as a source of water supply for domestic animals; (4) the killing of fish and the interference with the use of the stream for swimming and boating, and (5) various poorly defined health hazards.

C. C. R

Sludge drying and handling. ANON. *Public Works* **56**, 170-1(1925).—Sludge drying, handling and utilization, utilization of gas from sludge and glass covered sludge beds are briefly discussed

C. C. RUCHHOFF

Lime in sewage treatment. T. C. SCHMITZLE. *Public Works* **56**, 171-2, 201-3(1925).—At the Hagerstown, Maryland, sewage works 1800 gals. of raw sludge with a water content of 92.7% is removed from the Dorr clarifiers daily and treated with 300 lbs. of lime. The lime-treated sludge can be spread on farm land with less nuisance from odor than from raw sludge. Difficulty in drying the lime-treated sludge is overcome by adding FeSO_4 at the rate of 124 grams per gal.

C. C. RUCHHOFF

Cleaning Haskell septic tanks. ANON. *Public Works* **56**, 211-2(1925).—The sludge was pumped with a 3 in. diaphragm force pump through 700 ft. of 2 in. hose to a field.

C. C. RUCHHOFF

Biochemical oxygen-demand test. J. A. CHURDS. *Public Works* **56**, 218-9(1925).—The application is discussed of the O demand test to the operation of sewage treatment plants and to the study of industrial wastes and stream pollution.

C. C. R

Sewage treatment plant at Boonton. CYRIL POISS. *Public Works* **56**, 231-4(1925).—The plant described is designed for a population of 20,000 and consists of settling tanks, sep. sludge digestion tanks, sludge beds, contact beds, sand filters and sterilization plant.

C. C. RUCHHOFF

Control of odors from sewage treatment plants. J. F. SKINNER. *Surveyor* **67**, 499-500(1925), cf. *C. E.* **19**, 2097. Liberal design and proper placing of the plant are at the present the most efficient method of odor control.

R. E. GREENFIELD

Percolating bacteria beds. J. T. THOMPSON. *Surveyor* **68**, 31-4(1925).—Percolating beds successfully purify sewage pptd. with iron and lime at Leeds, England. A 24-hr. B. O. D. test on the effluent is advocated for sewage plant control using the "Miller" method for dissolved O.

R. E. GREENFIELD

Sewerage of towns on tidal waters. N. BALFOUR. *Surveyor* **68**, 100-10(1925).—Discharge of sewage in tidal streams or estuaries is often unsatisfactory. Where sewage is discharged in such a way as to reach the open sea quickly, especially if the sewage has been clarified, conditions are usually less objectional.

R. E. GREENFIELD

"Distillery waste liquor" and their purification. (LITTLEFIELD) **16**. Filter for water (U. S. pat. 1,556,426) (U. S. pat. 1,558,608) **1**.

Purifying air containing ammonia. G. ST. J. PERROTT and M. YARLICK. U. S. 1,559,980, Nov. 3. Air which is vitiated by a large content of NH_3 is rendered respirable by passing it through a dry granular mass contg. crystals of hydrated CuSO_4 which may be mixed with pumice.

Preventing hard scale formation in boilers. J. SCHERT. U. S. 1,557,349, Oct. 1. Scale is removed and its formation prevented by emulsifying olibanum or other resin with the boiler H_2O by the use of gum arabic, agar agar or other org. protective colloid.

Filter for water. C. B. DEMAREE. U. S. 1,559,941, Nov. 3.

Combining soda ash and water. J. A. BRADBURN. U. S. 1,557,974, Oct. 20. Mech. features.

Portable water filter. A. M. CAPRA. U. S. 1,556,913, Oct. 13.

Apparatus for deaerating water. B. BROIDO. U. S. 1,560,754, Nov. 10.

Apparatus for softening water with base-exchange material. O. R. SWENEY. U. S. 1,557,117, Oct. 13

15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

What is humus? S. A. WAKSMAN. *Proc. Nat. Acad. Sci.* **11**, 463-8 (1925).—Soil humus may be divided into 2 fractions, α and β . The α fraction is sol in dil alkali and not pptd by dil acid. The β fraction is sol both in dil acids and dil alkalis and is pptd at a more or less definite isoelectric point which lies close to pH 4.8. Analyses of the α and β fractions of a muck soil and of fertilized and unfertilized Sassafras soil are given. Fertilizing greatly increased the α fraction of the Sassafras soil, while the β fraction was little changed. The muck contained 31.5% α fraction and only a trace of the β . M. S. ANDERSON

Some adsorption effects. F. GIRAUD. *Rec. agr. Mauricie* **2**, 507-9 (1925).—Examples of adsorption effects are cited. Eight samples of Mauritius soils were digested in $(NH_4)_2SO_4$ solns. of varying concn., and the NH_4 was detd. at the beginning and again after 18 hrs. From the av. results the following equation is derived: $A = 1.23 M^{0.69}$, where A is NH_4 adsorbed by 100 g. of soil, and M is NH_4 in 100 cc. of the final soln. It is concluded that even an excessive rain would not diminish the NH_4 in the soil, but would even increase it, through its own NH_4 content. Cane trash also adsorbs NH_4 , as is shown by a distinct temp. rise noted. It is probable that stable litter has a similar effect. F. W. ZERBAN

Disperse systems in soils. K. GLINKA. Separate 178 pp. Publishing house "Obrasovaniye," Russia (1924). This monograph from the eminent Russian authority is a concise statement of the present status of the subject soil colloids. The subject is treated under the following headings: conception of dispersed systems, soil suspensions, soil colloids, the phenomenon of adsorption in suspensions and colloids; elec. adsorption and coagulation, mutual pptn. of colloids, protective influence of humus sols, chemical (exchange) adsorption in soils, adsorption of gases and liquids (water) by soils, soil soln., application of the facts of dispersed chemistry to the problems of soil genesis. The monograph gives a comprehensive historical review of each subject treated and an extensive bibliography. J. S. JOFFE

Remarks on the determination of the acidity of the soil by the Liechti method. JAC. VAN DER SLEK. *Verslag Onderzoek. Rijkslandbouwk. proefsta.* **30**, 206-19 (1925).—Besides the large salt error of azolitmin, its colloidal character renders it unsuitable for use as an indicator for the detn. of the acidity of the soil. This is thought to be due to the pptg. action of the salt solns. on the colloids (clay and indicator), as well as the reaction of the azolitmin with the soil. The method is not recommended as a means of detg. the lime requirement of the soil. R. M. BARNETTE

Colloidal complications in the thiocyanate method of estimating soil acidity. F. O. ANDERSON and R. P. LUTZ. *Ind. Eng. Chem.* **17**, 1153-4 (1925).—Ferric thiocyanate in 95% alcohol when added to an air dry soil, hydrolyzes sufficiently to complicate the thiocyanate test for soil acidity. The $Fe(OH)_3$ formed by hydrolysis may be adsorbed by the colloidal clay of a soil, resulting in a shifting of the end point. The blue or green color often developed when soils high in Mn are treated with thiocyanate is thought to be due to a mutual pptn. of the negative colloidal Mn compds. and the positive $Fe(OH)_3$. M. S. ANDERSON

The soil with reference to some of its inorganic constituents. M. CARBERY. *Agr. J. India* **20**, 277-9 (1925).—Red laterite soil is of a fairly acid nature and contains a large % of Fe, Al and K_2O . It lacks P_2O_5 and N. The addn. of P_2O_5 in the form of bone was found to be very efficient. Liming was also necessary. The detn. of K_2O gave very good results with pte, although chem. analysis of the soil showed an ample supply of K_2O . Lab. expts. showed that the application of increased amts. of CaO decreased the amt. of available K_2O and, to a lesser extent, the P_2O_5 in soln. An application of 10 maunds of CaO per acre was found to be ample, although this quantity is not sufficient to bring the soil to neutrality. Field results are corroborating these lab. expts. RUSSEL M. JONES

A preliminary study of the effect of pressure upon the nitrogen changes in the soil.

E. H. PANGANIBAN. *Philippine Agr.* **14**, 235-42(1925).—Analyses of 3 soils from the vicinity of Cornell University are given. An additional pressure of 15 lbs. per sq. in. had no appreciable effect upon ammonification, nitrification, denitrification nor nitrogen fixation in soil. Eight references are given. A. L. MEHRING

Nitrogen fixation in the Punjab. P. E. LANDER AND BARKAT ALI. *Mem. Dept. Agr., India, Bact. Series* **2**, 28(1925).—Normal soils possess the power of rapidly fixing large quantities of N without the addn. of any carbohydrate. Under certain conditions, at present not exactly known, a rapid loss of N takes place. Light soils possess greater power of N fixation than heavy soils. More denitrification occurs in heavy soils than in light soils. Fixation of N occurs more often than denitrification. The rapid exhaustion of N from the soil will not occur from the above causes alone. Nature has provided to a certain degree a remedy for the loss of N which takes place by the removal of crops. A soil becomes suitable for N fixation after it has been exposed to climatic conditions for several months after the removal of wheat. RUSSEL M. JONES

A study of the secondary effects of hill fertilization. H. J. HARPER. Iowa Agr. Exp. Sta., *Research Bull.* **87**, 223-51(1925).—A field, lab. and greenhouse study of secondary effects of hill fertilization was made with 3 soil types. When fertilizers are applied in the hill acid phosphate had more effect on the H-ion concn. of the soil soln. than either $(\text{NH}_4)_2\text{SO}_4$ or KCl. There was no accumulation of NH_3 in the soil when the fertilizers were applied in the hill. Accumulation of NO_3 was retarded in a sandy soil, but no appreciable increase or decrease occurred in a loam or silt loam. There was very little leaching of NO_3 and other plant foods from a loam and silt loam from 1 in. of rainfall, while 2.56 inches caused a considerable movement of NO_3 . Hill applications of P in a loam soil were leached slightly by 1 in. of rain. During an entire season in which 15.27 inches of rain fell, the P_2O_5 from acid phosphate was not leached to a depth greater than 2 inches in a silt loam or greater than 4.5 inches in a loam. K is leached into the lower layers of soil more rapidly than P. No decrease in root development was detected between fertilized and unfertilized plants when the rate of hill fertilization did not exceed 200 lbs. per acre and the N content of the fertilizer did not exceed 3% of NH_3 . J. J. SKINNER

The experimental sullage farm, Lyallpur. P. E. LANDER. Agr. Research Inst., Pusa, *Bull.* **157**, 25 pp (1925).—The expts. are being carried out to det. the value of sewage H₂O as a fertilizer in India. Sep. exptl. plots were irrigated with full-strength sewage, 50 and 25% sewage dild. with canal H₂O, and canal H₂O alone, resp. The quantity of N applied during the growing season varied from about 75 lbs. with full strength sewage to 8 lbs. per acre with canal H₂O alone. Full-strength sewage gave the best results on maize and the yields paralleled the strength of the sewage regardless of the original fertility of the land. The highest yields of wheat were obtained with 25% and the lowest with full strength sewage, the latter producing a marked lodging effect on the wheat. Except in great dildn., sewage H₂O tended to cause cracking and bursting in root crops such as turnips and carrots, and produced an unpleasant flavor. Above-ground vegetables such as spinach and cauliflower were improved in condition and flavor by sewage applications. Variations in the total, nitrous, and nitric N content of the plots during the season are tabulated. K. D. JACOB

The phosphatic nodules of Trichinopoly and the availability of flour phosphate as a manure for paddy. M. R. RAMASWAMI SIVAN. *Mem. Dept. Agr., India, Chem. Series* **7**, 145-200(1925).—A deposit of phosphatic nodules, contg. 56 to 59% $\text{Ca}_3(\text{PO}_4)_2$, 17 to 20% CaCO_3 , 7% Fe_2O_3 and Al_2O_3 and 7% SiO_2 , is present in the cretaceous formation in the Trichinopoly district, lying on the surface and imbedded in soft yellow clay. A full description of the locality is given. The nodules are not suitable for superphosphate manuf., as the high % of CaCO_3 , Fe_2O_3 and Al_2O_3 will result in the waste of the acid. The conversion of the $\text{Ca}_3(\text{PO}_4)_2$ of the nodules into $\text{Ca}_2\text{H}_2(\text{PO}_4)_2$ is not feasible at present because of the lack of hydroelec. power. The nodules have, therefore, to be applied to the soil in a finely powd. condition. H₂O contg. CO_2 dissolves $\text{Ca}_3(\text{PO}_4)_2$ to an appreciable extent. The decompn. of org. matter, in the form of green manure, under swampy conditions of cultivation, results in the formation of sufficient CO_2 to convert appreciable quantities of $\text{Ca}_3(\text{PO}_4)_2$ into $\text{Ca}_2\text{H}_2(\text{PO}_4)_2$ which is sol. in soil H₂O. The availability of the phosphate in composts made with green manure and cattle manure was measured and found to be greatest in one week's compost and to decrease in longer kept composts. The results of pot expts. show that, when sufficient N is present in the soil, green manure renders the flour phosphate available to the paddy plant. Field expts. at the Manganallus Agr. Sta. and on the standardized plots of the central farm Coimbatore showed an increased yield of grain in favor of flour phosphate green manure, of 18 and 9%, resp. RUSSEL M. JONES

Pasture top-dressing trials at Te Kumi. T. H. PATTERSON. *New Zealand J. Agr.* 31, 88-92(1925).—With the check plots as 100 the relative av. yield of hay from unlimed plots receiving, resp., superphosphate, basic slag, and ground raw rock phosphate at the rate of 300 lbs. per acre each year over a period of 4 years, was 191, 152 and 149. On limed plots the relation was, check 100, superphosphate 178, and ground raw rock phosphate 130. With the 3 phosphatic materials the yield of hay progressively increased each year, the check plot showing practically no increase in yield. The limed superphosphate plot was practically free from weeds at the end of the fourth year and in this respect the other plots stood in the following order: superphosphate, unlimed; basic slag; rock phosphate, limed; rock phosphate, unlimed. The check plots showed an increase in weed vegetation. The soil used was a light loam with a somewhat stiffer subsoil. On medium volcanic loam and heavy alluvial soil the response from phosphatic fertilizing was less pronounced. K. D. JACOB

Liming and top-dressing at Winton experimental area. Botanical analysis, of pasture. R. MCGILLIVRAY. *New Zealand J. Agr.* 31, 107-10(1925); cf. preceding abstr.—Exptl. plots were sown to mixed pasture in 1920 and treated in 1924 with basic slag and ground, Nauru raw rock phosphate, resp., at the rate of 300 pounds per acre. In addn. to the phosphates, the plots also received either ground limestone at the rate of 1.8 to 3.6 or burnt lime at the rate of 1 to 2 tons per acre. With the check plots as 100, the relative yield with basic slag was 111 and with raw rock phosphate 91. On the av., higher yields were obtained from the plots receiving ground limestone than from those receiving burnt lime. Hay from the plots receiving both phosphate and lime lost 74% of its wt. on air-drying while hay from the check plots lost 76 to 80%. The percentage of weeds was practically the same on all plots. The basic slag plots contained the highest percentage of clover and the check plots the lowest. K. D. J

Trials with sulfur as a top-dressing at Yanco. R. J. DAVIDSON. *Agr. Gaz. N. S. Wales* 36, 548(1925).—S applied as a top-dressing, alone and in combination with superphosphate, did not appreciably increase the yield of lucerne. K. D. JACOB

The relation of sulfur to alfalfa production. O. C. BRUCE. *J. Agr. Research* 30, 937-47(1925).—S applied to a soil which contained as much of the fertilizing elements and a little more S than the av. Kansas soil failed to give any marked increase in yield or root development of alfalfa. S is, therefore, considered not to be the limiting factor in alfalfa production on this type of soil. In general the acidity of the soil was increased by the S. The N content of the tops and the S content of roots and tops were not influenced by the S applied. W. H. ROSS

The influence of sulfur and gypsum upon the composition and yield of legumes. J. R. NEILLER. Washington Agr. Expt. Sta., *Bull.* 190, 47 pp.(1925).—On Ritzville soil in the greenhouse yields of alfalfa were increased by the use of S and gypsum and contained an appreciably greater percentage of N. This suggests that S benefits alfalfa indirectly through its action on the nodule bacteria by enabling them to fix more N to be incorporated into the proteins of the plant. Results in similar expts. with clover grown on Ritzville loam were much the same as those with alfalfa, except that both S and gypsum increased the clover yields even more than those of alfalfa. The results on several soils show that when S is effective it causes an increase in the percentage of N as well as in the yield of legume crops. S proved to be more effective when used as a top dressing, in the surface layer of alfalfa sod, than when mixed with the surface soil before planting. This again points to the direct action of S upon the nodule bacteria since most of the nodules are found on roots near the soil surface. Although the sulfured and unsulfured crops contained approx. equal quantities of Fe it is believed that the Fe exists in a different state in sulfured crops because it has a different appearance when pptd. as a hydroxide. Analyses of alfalfa grown in Ritzville silt loam under plant-house and field conditions showed that the field crop contained larger quantities of N and S while the K, Ca, and P contents were about the same. In sulfured soils the plant-house crops contained slightly greater quantities of N and S. J. J. SKINNER

Limestones for agricultural use. F. T. LEIGHTON. *New Zealand J. Agr.* 31, 175-7(1925).—The CaCO_3 content and the general phys. characteristics of 39 samples of limestone from as many different localities in New Zealand are tabulated. K. D. J.

Seychelles guano deposits. P. R. DU PONT. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 10, 214(1925).—The deposits are of bird origin. They are estd. at 200,000 tons contg. over 50% $\text{Ca}_3(\text{PO}_4)_2$ and approx. 1,000,000 tons of lower-grade guano. K. D. J.

"Leuna"-saltpeter (ammonium sulfate-nitrate). C. H. VAN HARREVELD-LAKO. *Arch. Suikerind.* 33, 685-92(1925).—A review of previous articles on the subject by

Jänecke (Pamphlet, 1924), Kast (C. A. 18, 2079), Wöhler (Z. angew. Chem. 1924, 497), Schreinemakers and Hoenen (C. A. 3, 1733).

Sources of ammonia in potato fertilizers. J. G. LIPMAN. New Jersey Dept. Agr., Bull. 39, 171-7 (1924).—Mineral nitrates are more effective in potato fertilizers than animal ammoniates. The cost of each is discussed and the physical condition of mixts. made from various N sources is given consideration.

Experiments on the control of wart disease of potatoes by soil treatment with particular reference to the use of sulfur. W. A. ROACH, M. D. GLYNNE, W. B. BRIERLEY and E. M. CROWTHER. Ann. Applied Biol. 12, 152-90 (1925).—S applied to a light sandy soil at the rate of 100, 200, 300, 400, 500, and 1000 lb. per acre reduced the degree of infection of the potato wart disease in direct ratio from 73% for untreated soil to 8% for 1000 lb. per acre. Larger applications did not completely eradicate the disease. Heavy soils required larger applications of S to ensure clean plots. Gas works spent oxides were less effective than S, probably due to the coarseness of the material. S inoculated with *Thiobacillus thiooxydans* showed no increased efficiency over uninoculated S.

A study of essential plant foods recoverable from the manure of dairy cows. C. F. WELLS and B. A. DUNBAR. J. Agr. Research 30, 983-8 (1925).—About $\frac{4}{5}$ of the K_2O , $\frac{2}{5}$ of the P_2O_5 and $\frac{2}{3}$ of the N fed to lactating cows are recovered in the manure. The actual quantities of these constituents so recovered vary with the type of animal and with the daily milk production. In a very general way the recovery of K_2O and N is in inverse relation to milk production, while the P_2O_5 recovered parallels the production of milk.

Variations in samples of copper carbonate. A. A. RAMSAY. Agr. Gaz. N. S. Wales 36, 482-4 (1925).—The compn. of 6 samples of com. Cu carbonate sold for the treatment of bunt in wheat, and contg. $CaCO_3$ as a filler, varied as follows: Na_2CO_3 0.26-1.85, $NaHCO_3$ 0.53 (one sample only), Na_2SO_4 3.46-16.19, $CaCO_3$ 10.64-36.68, Fe_2O_3 and Al_2O_3 0.60-2.16, basic Cu carbonate 35.99-72.36, basic Cu sulfate 0.98-12.00, and insol. matter 0.19-10.06%.

Some orchard conditions affected by arsenicals, marls and other factors. W. P. HEADDEN. Colorado Agr. Expt. Sta., Bull. 294, 31 pp. (1924).—The unfavorable conditions of many orchards in Colorado are due to (1) corrosive action of As in the crowns of the trees which produces acute poisoning, (2) development of injurious quantities of nitrates in the soil, (3) spray materials finding their way in the soil and made soluble by the soil ingredients and (4) presence of marl in the many soils. A discussion of each factor is given. It was found that sick trees contained a higher percentage of ash in wood and bark than healthy trees. A complete chem. analysis of trees and orchard soils is given.

Effects of spraying citrus trees on the composition and flavor of the fruit. C. F. JURITZ. J. Dept. Agr. Union S. Africa 11, 240-3 (1925).—The acid and sucrose content of oranges from trees sprayed with Pb arsenate mixt. varied inversely as the amt. of spray used. The av. content of 80+ specimens from unsprayed, lightly sprayed (26 ounces of spray mixt. per tree), and heavily sprayed (53 ounces per tree) trees was, acid 1.12, 0.49 and 0.18%; and sucrose 4.14, 3.65 and 1.12%, resp. In general approx. the same ratio existed with different varieties of oranges. Spraying with Pb arsenate impaired the flavor of the fruit but produced no change in external appearance.

The dormant spraying of fruit trees. THEODORE PARKER. Fertilizer, Feeding-Staffs and Farm Supplies J. 10, 15 (1925).—A review of the properties and relative value of the more important sprays used for the dormant spraying of fruit trees.

Destruction of charlock and other weeds by finely ground kainite. G. A. COWIE. Fertilizer, Feeding-Staffs and Farm Supplies J. 10, 303-4 (1925).—Kainite ground to 80% through a 60-mesh sieve and dusted on at the rate of 600 to 800 lbs. per acre killed as high as 90% of the charlock present. For optimum results the kainite should be applied while the leaves are wet and before the weeds reach the flowering stage. Young clover was not injured when the kainite was applied at the proper stage of weed growth. Finely ground kainite was also effective against thistles, runc, spurry and stinging, and hemp nettles.

Calcium salts of the phenols from low-temperature tar. FREDERICK GREENBAUM. Chem.-Ztg. 49, 754 (1925).—The Ca salts of low temp. tar phenols were prepd. by boiling the phenols with an excess of $Ca(OH)_2$ in $CaCl_2$ soln., filtering off the ppt., and washing with C_6H_6 . The product contained 55% of the original phenol used. Tests showed it to be of no value as an insecticide for boll-weevil.

T. S. CARSWELL

Sulfur: Its uses as an insecticide and fungicide. THEODORE PARKER. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 10, 96-7(1925).—A review of the properties, compn., efficiency and methods of application of 7 S prepn.s. used as insecticides and fungicides. K. D. JACOB

Latex. Insecticide preparation for combating plant parasites. RUDOLF DITMAR. *Rev. gén. caoutchouc* 1925, no. 15, 9-10.—Rubber latex is an effective insecticide when used in either of 2 ways. On painting the tree trunks or branches, a sticky coating remains on evapn., to which the parasites adhere. By sprinkling the infested areas with the latex the insects are suffocated. In the first case honey can be added to dild. latex, or a soln. of rubber in benzene or benzine may be used, the former being particularly effective against ants. The efficacy of such prepn.s. is enhanced by the fact that oxidation due to sun and air renders them still stickier. C. C. DAVIS

Soap and its uses for spraying purposes. THEODORE PARKER. *Fertilizer, Feeding-Stuffs and Farm Supplies J.* 10, 211-2(1925).—Expts. were carried out to det. the relation between the strength and the spreading power of soap solns. used for spray purposes. The soap contained K_2O 8, fatty acids 40, and H_2O 50%. The hardness of the water used was 12.8 grains per gal.

Lbs. of soap per 100 gal. of water	Greased plate	Surfaces sprayed	
		Washed Ivy leaves	Unwashed
1	Bad	Bad	Good
2	Bad	Very good	Excellent
3	Very poor	Fair	Excellent
4	Fair	Good	Excellent
5	Fair	Good	Excellent
8	Moderately good	Good	Excellent
10	Good	Excellent	Excellent
20	Excellent	Excellent	Excellent

The unwashed leaves were covered with a thin adhesive layer of dust which appeared to reduce the natural resistance of the leaves and facilitate the spreading of even the most dil. soln. The importance of using relatively soft water in the prepn. of soap soln. for spray purposes is emphasized. K. D. JACOB

The poisoning of fruit flies. The killing efficiency of certain arsenicals. T. MCCARTHY. *Ag. Gaz. N. S. Wales* 36, 667 (1925). The expts. were carried out to det. the efficiency of certain As compds. as poisons for fruit flies (*Ceratitis capitata*). Flies were bred in the lab. from infested fruit and placed in glass lamp chimneys for a few days before being fed on the poison mixts. The baits were composed of a mixt. of molasses, H_2O , and Pb arsenate, Ca arsenate, As_2O_3 , Na arsenite, or K arsenate. On the basis of the time required to kill the flies after addn. of the poison to the glass chimneys, Na arsenite, K arsenate and As_2O_3 were the most effective, followed by Ca arsenate and Pb arsenate. The max. time required to kill all flies varied from 24 hrs. with As_2O_3 to 90 hrs. with Pb arsenate. The time required for death after actual feeding of the poison was detd. with individual flies with the following results: As_2O_3 25 to 78, Na arsenite 25 to 75 and K arsenate 45 to 65 min. K. D. JACOB

Fertilizer. J. GÖRNING. U. S. 1,550,537, Aug. 18. Waste liquor from the manuf. of cellulose is mixed with sufficient lime to form a dry fertilizer.

Fertilizer containing colloidal magnesium antimonate. M. NAMBA. U. S. 1,550,585, Aug. 18.

Insecticide. G. E. SEIL and O. F. HEDENBURG. U. S. 1,559,961, Nov. A dil. aq. soln. of ethanohydrin of acetone is adapted for spraying on plants, etc.

Fungicide containing sulfur. H. W. BANKS, 3D. U. S. 1,550,650, Aug. 18. A compn. contg. colloidal S is prepd. by melting S and mixing it with bentonite or other "morg. H_2O absorptive jell-forming medium" before it congeals.

16 THE FERMENTATION INDUSTRIES

C. N. FREY

The assimilative nitrogen in beer worts. PAUL KOLBACH. *Wochschr. Brauerei* 42, 245-6(1925).—The N in beer worts may be classified into 2 groups, one group contg. ammonia, amino and polypeptides N, the other contg. albumins, peptones and proteins. Yeast offers a means of testing for the compds. assimilated because only the

substances passing through membranes can be used by yeast. To avoid yeast autolyses, only a few cells of known purity are used for inoculation. All N measured as amino N by formol test is not fermentable and may not all be amino N. All N of arginine is probably not fermentable and some sol. nitrogenous substances may not yield to formol titration. This is true of certain polypeptides and of amides whose N content is only partly indicated by formol titration. The difference between the Van Slyke N and formol N gives the amt. of diamino acids. The polypeptide N may be detd. by using the same indicators but different solvents and titrating according to Willstätter's method. In 50% alc. polypeptides may be quant. titrated with phenolphthalein but amino acids only 28%. In 97% alc. both may be titrated quant. By these methods it is hoped to obtain some information regarding the N compounds assimilated by yeast. C. N. FREY

Malt content of worts and degree of fermentation. P. PETIT *Brasserie et malterier* 15, 177-80, 193 6, 209-12(1925).—The mechanism of fermentation is discussed from the standpoint of explaining the apparent inconsistencies frequently observed between detns. of "crude maltose" and of max. degree of fermentation and the degree of fermentation actually obtained. P. concludes that the detn. of max. degree of fermentation is of greater value than that of "crude maltose" (reducing sugars calcd. as maltose). A. PAPINEAU-COUTURE

"Distillery waste liquids" and their purification. R. D. LITTLEFIELD *Chemistry and Industry* 44, 860 7(1925).—Methods for the disposal of steep water, pot ale, spent lees and wash waters are given. Drawings illustrate the equipment used. C. N. F.

Observations on Sarcinae. F. STOCKHAUSEN *Wochschr. Brauerei* 42(1925); *Bull. assoc. inst. sup. fermentations Gand* 26, *Ann. soc. brasserie* 34, 272 3(1925).—Degree of fermentation seems to have considerable effect on the development of Sarcinae. It is considerably hampered by toxic substances from the hops and by the O dissolved in the wort. On addn. of the yeast, Sarcinae begin to develop as a result of absorption of O by the yeast and diffusion of the decompn. products of the yeast. Slow fermentation with poor yeast development greatly favors development of Sarcinae, as does the use of low diastatic malts which leave a large amount of residual dextrins in the wort and gives beers with abnormal acidity. Beers with low acidity are especially liable to Sarcinae infection. Development can take place with a p_H of 4.3-6.3, the optimum being 5.33. A. PAPINEAU-COUTURE

Fusel oil and the methods of producing it. D. E. LÜDDE *Z. Spiritusind.* 48, 297(1925).—The origin and methods of production of fusel oil are discussed. C. N. F.

Are there dextrin-fermenting yeasts? (STAIGER, GLAUBITZ) 11C. Chemical mechanism of the principal fermentations of glucose (LEMOIGNE) 11A.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

The stability of calcium acetylsalicylate. N. SCHOORL *Pharm. Weekblad* 62, 1166-72(1925).—The Ca salt of acetylsalicylic acid, or "soluble aspirin," marketed under various trade names, undergoes decompn. unless prepd. in the anhydrous state and protected from atm. moisture by sealing the bottle with lime. In a cork-stoppered bottle decompn. is noticeable within 5 years. A. W. DOX

Alkaloids of ipecac (Uragoga ipecacuanha) IV. O. KELLER AND X. BERNHARD *Arch. Pharm.* 263, 401-24(1925); cf. *C. A.* 8, 2700; 11, 3093.—Emetine HBr, emetine and cephaeline were prepd. in pure condition and investigated anew. The behavior of both alkaloids on methylation via Hofmann-Nölting was compared with the result that both the quaternary iodides thereby formed are shown to be dissimilar in that the phenol OH of cephaeline is not methylated by this method. The behavior of emetine, cephaeline and the quaternary emetonium base was followed on distn. with Zn dust in an improved app. (illustrated) and the new compd. formerly designated "base X" again studied insofar as the scanty material permitted. The phenol isolated in this operation proved to be guaiacol. These expts. prove that not only cephaeline but pure emetine as well yields guaiacol though in somewhat smaller amt. Freshly prepd. emetine-HBr contains 3 mols. H_2O of crystn. but gradually passes into a more stable form contg. 4 mols. of H_2O . The pure emetine base was isolated in cryst., form m. 68°. The fully methylated emetine, via Hofmann-Nölting trimethylemetine diiodide m. 222° and contained 3 mols. H_2O of crystn. The "base X" resulting from distg.

both emetine and cephaeline with Zn dust yields an aurate and platinate indicating similarity to but not complete identity with NMe₃. The article concludes with a bibliography covering work heretofore reported on the alkaloids of ipecac. W. O. E.

Unpleasant taste of radix primulae. R. WASICKY. *Arch. Pharm.* 263, 424-30 (1925).—An exptl. study of the root shows that the terrestrial portions of both *Primula veris* as also of *elatior* contain a substance or mixt. of substances to which is due the unpleasant or irritating taste peculiar to preps. of the root. This substance, while not identical with saponin but may be sepd. therefrom, is sol. in both neutral, alk. and acid H₂O. The composition of this substance, temporarily designated "Pr.melkratzstoff," is still under investigation. W. O. E.

Constitution of hydrargyrum salicylicum and related compounds. F. BOEDECKER AND O. WUNSTORF. *Arch. Pharm.* 263, 430-5 (1925).—As ordinarily carried out, the mercurization of salicylic acid yields a variable mixt. of *o*- and *p*-hydroxymercurisalicylic acid, with which KCN reacts in concd. aq. soln. to yield the corresponding K salts of cyanmercurisalicylic acid, the one designated "salt A," C₆H₄O₂NHgK + 2½H₂O, forming short needles; the other "salt B," C₆H₄O₂NHgK + 2H₂O, long needles. A dissolves in H₂O to a clear neutral liquid of unlimited stability. Both salts yield with iodized KI iodosalicylic acids, that from A m. 197.5-198°, while the one from B m. 196°; their mixt. m. 170°. W. O. E.

Chaulmoogra oil and its saponification. FREDERICK GREENBAUM. *Oesterr. Chem.-Ztg.* 28, 109-10 (1925).—Based upon the sapon. value of 204 to 213, 50 g. of the oil were shaken in a glass-stoppered cylinder with 14.25 g. of NaOH dissolved in 50 g. of H₂O. The clear bright yellow oil became cloudy, thickened after a few min. and finally yielded a white cake. After standing 12 hrs. the sapon. is complete and the product may then be dissolved in hot H₂O to a clear golden yellow liquid, the soap soln. having a strength of 10% and contg. about 5% chaulmoogra oil. A higher concn. is obtainable only after recourse to alc. sapon. To this end shake 13 cc. of chaulmoogra oil with 40 cc. of a 10% alc. NaOH soln. The sapon. is immediate, the oil solidifying in 1 to 2 min. to a bright yellow cake. On adding cold H₂O to this product a clear soln. immediately results without application of heat. The soap thus prepd. is much more readily sol. in H₂O than that made with aq. NaOH. Thus a 20% soap soln. was easily obtained contg. 10% chaulmoogra oil, likewise a 40% soap soln. contg. 20% oil, which latter was perfectly clear and so remained even on long standing. Since the soap was desired for intramuscular injection in the treatment of tuberculosis, the alc. was first eliminated by heating the product in vacuum and the free alkalinity neutralized by the addn. of about 2 cc. of concd. HCl. W. O. E.

Preparation of extracts under diminished pressure. ERNST RICHTER. *Pharm. Ztg.* 70, 1348 (1925).—A procedure is outlined for the lab. prepn. of dry exts. under diminished pressure by the aid of a H₂O-blast pump. W. O. E.

Stability of iodoform gauze. SCHULTZEN. *Pharm. Ztg.* 70, 1348 9 (1925).—Examin. of CHI₃ gauze prepd. for the Ger. army during the period of 1915-18 showed very little loss or deterioration. W. O. E.

Mel depuratum D. A.-B. V. PAUL ARAUNER. *Pharm. Ztg.* 70, 1349 (1925).—A discussion of this product from the Ger. pharmacopeial standpoint. W. O. E.

Scientific principles of galenical pharmacy. A. TSCHIRCH. *Pharm. Zentralhalle* 66, 549-52 (1925).—A discussion of the principles involved in the prepn. of galenicals, whether made from the fresh or dried plant, in connection with the contemplated Swiss pharmacopeial revision. Also in *Am. J. Pharm.* 97, 694-9 (1925). W. O. E.

Adsorption value of carbo medicinalis. FRANZ KÖNIG. *Pharm. Zentralhalle* 66, 645-8 (1925); cf. *C. A.* 17, 2473.—The adsorption value of various samples of charcoal (powdered, granulated and tabletted) with respect to its "sublimate titer" (= the no. of mg. of HgCl₂ adsorbed by 1 g. of carbo medicinalis after a 5 min. contact with 0.02 N HgCl₂ soln.). It is suggested that this test be made as supplementing that with methylene blue. W. O. E.

Argentum permanganicum. J. MESSNER. *Pharm. Zentralhalle* 66, 650-1 (1925).—This rather unusual medicament is discussed from the standpoint of pharmaceutical availability and probable application in gonorrheal therapy. W. O. E.

Examination of ammoniated mercury ointment (Unguentum hydrargyri album). JOH. PINNOW. *Pharm. Zentralhalle* 66, 685-9 (1925).—In a discussion and exptl. consideration of the factors affecting the accuracy of Rupp's procedure in the evaluation of this ointment, it is shown that the reduction of HgKI₂ in alk. soln. by CH₂O is a time reaction, being practically complete in 2 min. Lowering of temp. and especially the presence of undue amts. of free mineral acid in the Hg salt soln. affect the reaction unfavorably, even when, after completion of the reduction, the liquid reacts alk. The

acid ext. of the salve prep'd. *via* Ger. Pharm. V. contains sufficient HCl to inhibit completion of reduction in 2 min. This difficulty may be overcome by the addn. of a larger initial amt. of alkali (det'd. by titration of an aliquot with methyl orange as indicator), otherwise the reduction should be extended over a period of 1.5 hrs. before the addn. of AcOH. The action of CH_2O on the I soln. is not appreciably prejudicial to Rupp's procedure, statements by Kolthoff and Keijzer to the contrary notwithstanding. W. O. E.

Estimation of arsenic in iron pills. ALBERT HANSEN. *Pharm. Zentralhalle* 66, 701 (1925).—In a 300 cc. Kjeldahl flask (special form by Ramberg and Sjöström provided with a ground in delivery pipet, the upper limb of which is bent at an angle of about 45°) contg. 10 to 15 cc. of H_2O introduce 5 to 10 pills, and after $1\frac{1}{2}$ hr. 20 cc. of fuming 80% HNO_3 in small portions (cooling if necessary to avoid loss by undue foaming), then follow with 25 to 28 cc. of H_2SO_4 in small portions, finally heating the flask placed obliquely on an asbestos gauze with a small flame until most of the HNO_3 has been expelled. While the liquid still boils run in drop by drop 8 cc. of fuming HNO_3 , heat more strongly until SO_3 fumes appear. If on cooling any gray or black particles are observable among the pptd. sulfates, add 10 cc. additional fuming HNO_3 and boil until SO_3 fumes again appear. To the residue thus freed from org. material add 30 cc. of sat'd. $(\text{NH}_4)_2\text{C}_2\text{O}_4$ soln., whereby nitrous fumes should appear. Again boil until SO_3 fumes appear, continuing for 10 min. to insure complete destruction of the $\text{C}_2\text{O}_4\text{H}_2$. After cooling add 20 cc. of H_2O , mix and cool completely, then add 30 g. KCl, 1 g. $(\text{NH}_4)_2\text{SO}_4$ (or 0.5 g. FeSO_4), 25 cc. of concd. HCl and 0.5 g. of KBr. Mix thoroughly, adjust obliquely on a wire gauze, connect with the ground-in and bent pipet (lower end of which extends 1 cm. into 150 cc. of H_2O cont'd. in an Erlenmeyer flask, the latter being surrounded by 2 l. of cold H_2O). Now distil with such rapidity that the bent portion of the pipet becomes hot after 4 min., the bulb portion after 8 min., cooled, from the time of applying the heat. The distn. is complete after the lapse of 10 min. Raise the retort and attached pipet before extinguishing the flame, remove and drain the pipet, add 2 drops of methyl orange soln. (1:2500) to the distillate, then run in drop by drop from a buret a soln. contg. 0.2812 g. KBrO_3 per l. until the red color entirely disappears. This addn. of KBrO_3 must be very slow at the end. When the liquid begins to fade such addn. should not exceed 1 drop per min. The color change should not be immediate, but gradual. After the titration is finished add another drop of methyl orange soln. whereupon the red color should persist at least 1 min. 1 cc. KBrO_3 reagent = 0.5 mg. As_2O_3 . The app. employed is shown in 2 illustrations in the original. W. O. E.

Determination of chloroform in chloroform liniment. T. M. WILLGERODT. *Am. J. Pharm.* 97, 584 (1925).—W. recommends the following method based upon the conversion of the CHCl_3 into chlorides and detn. of the latter by the usual Volhard method: Pipet a 5 cc. sample of CHCl_3 liniment into a 100 cc. pressure bottle contg. 40 cc. of alc. KOH. The latter is made by dissolving 30 g. KOH in 30 cc. water, and when cool, adding enough MeOH to make 100 cc. Close the bottle, shake and boil 10 min. on a water bath. Start counting the time only when the water is actually boiling. Allow the mixt. to cool. Transfer with water into a 500 cc. volumetric flask, make up to vol. with water, pipet a 10 cc. portion into a 100 cc. volumetric flask, add a few cc. of HNO_3 , add a little water and then 50 cc. of 0.1 N V. S. AgNO_3 . Make up to vol. with water. Shake thoroughly. Filter off the chlorides with a dry filter. Take a 50 cc. aliquot portion, add a few cc. ferric ammonium sulfate soln. and titrate with a 0.1 N V. S. KCNS. Each cc. of 0.1 N AgNO_3 V. S. is equiv. to 3.98 mg. of CHCl_3 . W. G. GAESSLER

Studies on the toxicity of iron cacodylate. PETER MASUCCI AND GEO. A. SLOTHOWER. *Am. J. Pharm.* 97, 587-8 (1925).—Solns. of iron cacodylate on the market when injected intravenously give rise to abnormal irritation, pain and systemic reactions. By hydrolyzing the salt and converting the iron into the colloidal form, the drug is better adapted for intravenous use. Animal expts. show that the colloidal iron is one-half as toxic as the iron in the ionic state. Clinical results show very conclusively that when the iron is in the colloidal state the administration of the drug is not attended by any objectionable features. W. G. GAESSLER

Studies in the genus *Mentha*. VII. An examination of an oil of *Mentha piperita*, L., produced in 1922. R. E. KREMERS. *Am. J. Pharm.* 97, 658-64 (1925).—An oil derived from the strain of *M. piperita*, L., which has been grown for a number of years in the gardens of the Wisconsin Pharmaceutical Expt. Sta. was studied. This investigation has not settled either the entire compn. of the oil or the reasons for the difficulty in the crystn. of menthol. The previously well-known constituents cineole, *l*-menthol,

and *l*-menthone were identified. Neither 1-methyl-3-cyclohexanone nor pulegone was found in the cohobated oil of this year. Neither pinene nor phellandrene nor limonene, which have been previously reported, was definitely characterized. The possibility of another terpene being present in the mixt. of low-boiling substances is worth considering. *d*-Piperitone was identified in both the cohobated and primary oil. A menthenone closely resembling pulegone was found in the primary oil. Although no conclusive evidence was obtained, the indications were that other alcs. than *l*-menthol were present in the menthol-menthone fractions and were the principal cause for the failure of *l*-menthol to crystallize from high concns. W. G. G.

Stability of iodated tincture of iodine. E. COLLARD, JR. *Ann. chim. anal. chim. appl.* 7, 292-3 (1925).—A tincture of I_2 prepn about $3\frac{1}{2}$ years old was analyzed by the method previously described (Collard, *C. A.* 16, 4008). Its d had increased from 0.901 to 0.910, the KI content from 2.66 to 3.02 and the total I from 6.67 to 7.28 while the alc. content was reduced from 93° to 89.5° . The changes were so slight, however, that the values testify to the fact that the tincture prepd. according to *Codex* has good keeping qualities. W. T. H.

Extraction of nicotine from waste Turkish tobacco. F. W. PETTY AND A. SKIBBE. *J. Dept. Agr. Union S. Africa* 11, 294 (1925).—Preliminary expts. on the prepn. of home-made tobacco exts. showed that contrary to general opinion only about 3% of the total nicotine was lost by boiling the tobacco in H_2O for 30 min. or longer. Exts. from equiv. amts. of tobacco treated with cold H_2O for 12 hrs. or with boiling H_2O for 30 min. contained 0.083 and 0.076% of nicotine, resp. Exts. contg. from 0.05 to 1% nicotine were effective against the black peach aphid. K. D. JACOB

Water content of export butter. Results of testing for year 1924-25. ANON. *New Zealand J. Agr.* 31, 184-5 (1925).—Of 145,780 samples of butter examd. 828 contained an av. of 16.38% H_2O and the remainder an av. of 15.04%. The legal limit is 16%. K. D. JACOB

Farnesol. J. GROSJEAN AND J. MARTINET. *Chimie et industrie* 14, 363-7 (1925).—Review of the chem. properties and constitution of farnesol and of *nerolidol*. A. P.-C.

Oil of "Blumea Balsamifera." ÉTABLISSEMENTS A. CHIRIS. *Parfums de France* No. 31, 257 (Sept., 1925). According to R. JONAS (*C. A.* 3, 1908) this oil consists mainly of *l*-borneol, together with some cineol limonene, palmitic and myristic acids, *l*-camphor, sesquiterpene alcs., and the dimethyl ether of phloracetophenone. A sample from the Langson region, Tonkin, was found to consist mostly of *d*-camphor, with a small proportion of borneol, which could not be definitely identified as the *l*- and *d*- variety. A. PAPINEAU-COUTURE

Oil of "bergamot-mint" (*Mentha citrata*). ANON. *Parfumerie moderne* 18, 205-6 (1925). A sample distd. from *M. citrata* grown in Michigan had d_{25} 0.9234, α (100 mm.) -7.8° , n 1.4598, sol. in 15 vol. of 70% alc. and in 5 vol. of 60% alc., residue on evapn. 23%, esters (as linalyl acetate) 57. alcs. (as linalool) 14.6%. Tables are given showing the color, d_{25} , α (100 mm.), and n of the fractions obtained by steam distn.; and the color, d_{15} , d_{25} , α (100 mm.), n , acid no., ester no., % of esters (as linalyl acetate) or of alc. (as linalool) and soly. in 70% alc. of the various fractions on distg. under 15 mm. pressure. A. PAPINEAU-COUTURE

Identification by chemical methods of drugs containing tannin. A. H. WARE. *Pharm. J.* 115, 131-5; *Chemist and Druggist* 103, 174-5 (1925).—I. A specific method for the detection of aromadendrin. (A.) Shake an aq. ext. of powd. kino or cutch with Et_2O , dissolve 0.005 g. of the evapd. Et_2O ext. in 5 cc. of 90% $EtOH$, and reduce with Zn or Mg and HCl. A strongly pink color appears which later fades. NaOH added at the max. intensity causes a yellow color. The various kinos are classified according to their content of A as shown by this test. Flavonols, e. g., quercetin, give similar colors, except that with NaOH added at the max., the color is purple; added after fading, it is green. A, as well as anthoxanthins, gives the *kino-yellow test*: To a few cc. of an alc. ext. of kino in a white dish add a little dil. H_2SO_4 and heat thin films of the fluid to a temp. short of carbonizing. A very decided, at times brilliant, but evanescent yellow color is produced; it is also given with quercetin, luteolin and less strongly with gentisin. A weak indication of A runs parallel with an indistinct reaction for kino-yellow. A is probably benzophenone and resembles catechins (*C. A.* 18, 3183). II. Two new classificatory tests for tannins (cf. *C. A.* 19, 623, 3034). No. 1: Boil 5 cc. of dil. ext. with 10-12 drops of 33% $AcOH$ and 5 cc. of an aq. soln. of $Fe-NH_4$ citrate (Brit. Pharm.), cool, filter and add NH_4Cl 1 g., again boil. Pyrogallol tannin, but no phlobatannin, is pptd. Test for the latter in the filtrate by Stiasny's test (*C. A.* 18, 3684). This method differentiates sharply between the 2 classes, types of which are listed; *kousso* proved to contain pyrogallol tannin. No. 2: Boil 5 cc. of the ext. with

1.5 g. of small crystals of NaH_2PO_4 , filter and boil the filtrate with the ferric citrate soln. Gallotannins are pptd. partially or completely as violet Fe compds., and ellagitannins as green-black ppts.; hamamelitannins are not pptd., but give a deep brown soln. Phlobatannins are not pptd., but are better identified by the 1st test. The results by test No. 2 agree with those by Mitchell (*C. A.* 19, 2004) and certain other tests (*C. A.* 19, 3144). III. Table for the identification of seventeen kinos. A systematic application of the various tests for tannins.

S. WALDBOTT

The picrates of the opium alkaloids. C. W. MAPLETHORPE AND N. EVERS. *Pharm. J.* 115, 137-9, 178; *Chemist and Druggist* 103, 176-7 (1925); cf. *C. A.* 16, 1721.—The prepn. and analysis, and the methods of detn. of m. p., and soly. in H_2O , EtOH and acetone, are described. Sketches of the crystals are given (in *Pharm. J.*). The m. p. of the picrates of thebaine (217°), narcotine (174°) and narceine (195°) differ widely from those given by Fuller (*C. A.* 15, 1057). Soly. at 20° in H_2O , abs. EtOH and acetone of the picrate of morphine is, resp., 0.22, 0.14, 13.86%; codeine 0.11, 0.095, 3.89%; thebaine 0.20, 0.10, 10.1%; narcotine 2.02, 0.13, 0.30%; narceine 0.027, 0.01, 5.23%; papaverine 0.007, 0.052, 1.89%. At 15° the picrates of cryptopine (A), gnoscopine (B) and xanthaline (C) showed soly. in the same solvents of: A 0.007, 0.009, 0.162%; B 0.009, 0.04, 2.34%; C 0.01, 0.022, 0.34%.

S. WALDBOTT

Increase in specific gravity of Easton's sirup and Syr. ferri phosph., Brit. Pharm., on keeping. C. M. CAINES AND N. EVERS. *Pharm. J.* 115, 139, 178; *Chemist & Druggist* 103, 177 (1925).—The sp. gr. of a sample of Easton's sirup increased in 4 months from 1.2714 to 1.2828; another in 3 months from 1.2818 to 1.2945. The sp. gr. of a sample of syr. ferri phosph., Brit. Pharm., rose in 3 months from 1.2765 to 1.2890. In all cases the increase ran parallel with a decrease in optical rotation. The change is sufficiently accounted for by the inversion of the cane sugar content (cf. Rosenblum and Callaghan, *Australian J. Pharm.* 1924, 1114).

S. WALDBOTT

Identification of alkaloids. W. M. CUMMING AND D. G. BROWN. *Pharm. J.* 115, 140-3, 178; *Chemist & Druggist* 103, 177-8 (1925).—Results obtained previously (*C. A.* 19, 2826) on the action of ferro- and ferricyanides on alkaloids in neutral, acid or alc. solns. are given in a table contg. the formulas and the (characteristic) % of Fe for each of 36 compds. Micrographs of 14 salts are shown (in *Pharm. J.*). Also cf. *C. A.* 18, 59, 1799, 2330.

S. WALDBOTT

Note on the official process for assaying galenicals of hydrastis. H. B. MACKIE AND H. A. CLEARY. *Pharm. J.* 115, 145-6, 179; *Chemist & Druggist* 103, 179-80 (1925).—In the Brit. Pharm. process, the sepn. of berberine and hydrastine as HI compds. while incomplete is unimportant because the subsequent removal of hydrastine by means of a solvent effects a good sepn. Sources of error are the adsorption of hydrastine by the berberine-HI ppt.; also the soly. of hydrastine in excess of NH_4OH , possibly affecting the subsequent soly. in Et_2O ; hence excess of NH_4OH should be avoided. A process of extn. involving only the use of a suitable solvent is in prepn.

S. WALDBOTT

Some experiments on phosphorus pill, Brit. Pharm. F. J. DYER AND R. MELVILLE. *Pharm. J.* 115, 146-7, 179-80; *Chemist & Druggist* 103, 180 (1925).—The Brit. Pharm. formula yields a mass which melts in the hands and is difficult to form into pills. The use of dried Na_2SO_4 in the Brit. Pharm. prepn. seems to have little advantage upon the disintegration of the pill which, with or without Na_2SO_4 , melts at 37° in 5 min. Formulas with stearin, suet and wax, used in place of cocoa butter, gave a more manageable mass, but the pills failed to disintegrate in 1 day. The formula: phosphorated suet 10 g., powd. licorice 56 g., glucose 34 g., CS_2 20 cc., worked as in the Brit. Pharm. prepn., gave an excellent mass, fuming very little, easily rolled, cut and rounded. The pill disintegrates at 37° in 1 hr. The use of free P in pill form should be replaced by some other method, e. g., Oleum phosphoratum administered in capsules.

S. WALDBOTT

Note on oiled mercury. F. J. DYER AND KATHLEEN METCALFE. *Pharm. J.* 115, 147-9, 180; *Chemist & Druggist* 103, 180 (1925).—To obtain a uniform product, triturate HgO 20 g. with 90% EtOH 5 g., and to the moist mass add oleic acid 80 g. Heat on the water bath for 20 min., stirring occasionally. The result is a translucent, unctuous, lemon-yellow substance which should not darken or become opaque on keeping. One g. shaken with 20 cc. Et_2O produces a translucent soln. from which no yellow or gray particles sep. on standing.

S. WALDBOTT

Note on morphine hydrate. D. B. DORR. *Pharm. J.* 115, 137; *Chemist & Druggist* 103, 181 (1925).—Powd. morphine (0.5 g.) heated to 98.5° in a closed space surrounded by steam became anhyd. in 2 hrs. +. At 90° (e. g., on a water bath) the loss of H_2O is very slow. Heating to 100 - 110° in an air bath is recommended, but loss

through scattering of crystals, caused by tenaciously held H_2O , should be avoided.

Bismuth carbonate; some factors affecting its physical condition. A. J. JONES. *Pharm. J.* 115, 143-4, 179; *Chemist & Druggist* 103, 179(1925).—The formation of Bi carbonate of max. bulk depends on a restricted set of conditions in which the concn. of the Na_2CO_3 soln. remaining at the end of the reaction (1.26%), and the temp. of the reaction (45°) are the dominant factors. Deviations from these conditions tend to the formation of denser products.

Colorimetric estimation of benzoic acid in cordials, etc. A. J. JONES. *Pharm. J.* 115, 144-5; *Chemist & Druggist* 103, 181(1925).—A modification of the Halphen-Grossfeld reaction is used. Ext. a mixt. of 10 cc. of sample and 5 cc. 10% H_2SO_4 with 20 cc., then 10 cc. of a mixt. (equal vols.) of petroleum ether and Et_2O , and remove $BzOH$ with 5 cc. H_2O contg. 0.3 cc. 20% $NaOH$, then with 5 cc. H_2O . Evap. to dryness, add a total of 8 cc. of a mixt. (1 + 9) of HNO_3 (d 1.42) and H_2SO_4 (d 1.84) and heat in a test-tube by direct flame to 155-160° for exactly 3 min. Cool, add 20 cc. H_2O , again cool, then ext. with 15 and 10 cc. Et_2O . Ext. the Et_2O soln. with a mixt. of 8 cc. H_2O and 2 cc. NH_4OH (d 0.880), then with 2×5 cc. H_2O . Now add 3 cc. NH_4OH and 1 g. $NH_4OH.HCl$ and warm to 35-40°. A fine red color of $m-C_6H_3(NH_2)_2CO_2NH_4$ appears. After 20 min. dil. to 50 cc. and compare with a standard representing 5 grains of $BzOH$ per pint of sample if the standard is prepd. from 5.7 mg. $BzOH$ by the above method (6.7 mg. by calcn.). The deviation is caused by the fact that the color intensity is not strictly proportional to the amt. of $BzOH$ originally present. Salicylic acid at the high temp. of the method gives a negative test; saccharin reacts but slightly.

S. WALDBOTT

Filter for beverages, pharmaceutical solutions, etc. (U. S. pat. 1,560,266) 1.

Mercurial "prophylactic." O. LOWY. U. S. 1,559,899, Nov. 3. $HgCl_2$ is added to diaminodihydroxyarsenobenzene in a carrier of firm gelatinous material such as gelatin and glycerol which becomes substantially fluid at body temp.

Calcium lactate composition adapted for pharmaceutical uses. H. UMBER. U. S. 1,559,478, Oct. 27. A compn. comprising Ca and Na lactates and H_2O of crystn. is prepd. by mixing concd. lactic acid, $NaOH$ and quicklime.

Complex gold compounds. M. BOCKMÜHL, G. EHRHART and P. FRITZSCHE. U. S. 1,558,584, Oct. 27. A Au salt, e. g., K auribromide, is caused to act upon thiobenzimidazolecarboxylic acids and the Au compds. thus obtained are converted into salts, e. g., by use of $NaOH$. The products are yellowish powders, sol. in H_2O , adapted for therapeutic uses.

Acetylene as an anesthetic. H. WIELAND. U. S. 1,561,130, Nov. 10. C_2H_2 in such purified form as to be non-toxic is mixed with geraniol, linalool or other "cyclic fragrant alc."

Dentifrices. L. MANDELSTAMM. U. S. 1,559,732, Nov. 3. Glycerol and neutral cleansing and abrasive materials such as powdered chalk, soap, KCl and flavorings are mixed with small quantities of V and Ra compds., e. g., the chlorides.

Medicinal compounds of quinine and arsenic. DAFERT-SENSSEL-TIMMER. U. S. 1,558,241, Oct. 20. Quinine compds. such as the hydrochloride or the free alkaloid or quinidine and an As halide, e. g., $AsCl_3$ or AsF_3 , by reaction together (at a temp. of about 16-25° or lower in $CHCl_3$) form double compds. which are adapted for intravenous or intramuscular injection.

Acridinium salts soluble in fats and oils. L. BENDA. U. S. 1,550,420, Aug. 18. Mineral acid salts, e. g., the chloride of a 3,6-diamino-10-alkylacridinium compd., are caused to interact with Na stearate or other salts of such fatty acids as are contained in natural fats. The dry products are orange-red powders, insol. in H_2O but sol. in fatty oils and alc. They are adapted for use as therapeutic agents.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Control of the density of milk of lime by a simple titration. M. BECKMAN. *Arch. Suikerind.* 33, 1004-7(1925).—Instead of measuring the d. of milk of lime with a Baumé spindle, which is a very inaccurate method, it is better to titrate with HCl in a Vision tube, about 20 cm. long over all, and 17.5 cm. from bottom to beginning of neck. The

diam. of the tube is 23-25 mm. and of the narrow part of the neck 14-15 mm. The zero mark is placed at the point reached by 10 cc. Above that a graduation mark is placed every 2 cc. up to the 20 mark which indicates, therefore, 40 cc. added acid. If the 15 mark is to indicate milk of lime of 15° Bé., the HCl used must be 1.76 N. If it is preferred to use 1.5 N HCl, the cc. of this acid necessary to neutralize 10 cc. milk of lime of from 10 to 20° Bé. may be found from a table shown. Phenolphthalein is used as indicator.

F. W. ZERBAN

Potash from greensand (glaucanite). J. W. TURRENTINE, C. W. WHITTAKER AND E. J. FOX. *Ind. Eng. Chem.* 17, 1177-81 (1925).—A process is described for the recovery of K_2O from greensand which consists in digesting the ore with H_2SO_4 ; filtering, concg. the filtrate to crystallize out the sulfates of Fe, Al and K; roasting the mixt. of sulfates at 500° to decompose the sulfate of Fe into Fe_2O_3 with regeneration of SO_3 ; and lixiviating the roasted mass to yield high-grade Fe_2O_3 , alum and K_2SO_4 . The insol. residue remaining after the digestion of the greensand with H_2SO_4 yields when purified by washing, drying and screening an absorptive siliceous material to which has been assigned the trade name of "Glaucosil."

W. H. ROSS

The manufacture of artificial horn (galalith). O. MEIER. *Caoutchouc and gutta-percha* 22, 12595-7, 12639-42, 12682-3, 12718-21, 12790-4, 12830-5, 12868-70 (1925).—The article includes the history and development of the industry, the principles, process, equipment and technic of manuf. with diagrams and illustrations, the raw materials employed and their treatment, the drying of casein and its properties, analysis and evaluation, the present status of the industry, prospects for its future and production statistics.

C. C. DAVIS

Ethylene glycol. A contribution of chemistry to the automobile antifreeze problem. G. O. CURME, JR. AND C. O. YOUNG. *Ind. Eng. Chem.* 17, 1117-20 (1925).— $CH_2(OH)-CH_2(OH)$ (b. 197°) possesses advantages of both $EtOH$ and $C_2H_5(OH)_2$, with disadvantages of neither, as an antifreeze soln. A 40% (by vol.) aq. soln. freezes at -15° F. (-26° C.). Its solns. are non-electrolytes, non-corrosive to metals and finishes, do not destroy rubber, are not lost through evapn. of the glycol and so can be brought back to strength by the addition of H_2O , maintain temps. near the b. p. of pure H_2O when used in condns. indicated, and therefore give optimum engine temps., have high heat capacity and low viscosity, are odorless and noninflammable. Glycol can now be made in quantity without disturbing the production of other commodities and at diminishing rather than increasing cost.

W. C. EBAUGH

Occurrence of I in cement flue dust (KEYSSNER) 20.

Sulfuric acid. J. V. SKOGLUND. U. S. 1,559,292, Oct. 27. In recovery of nitrous gases from H_2SO_4 manuf., the gases are treated with H_2O and residual gases are then absorbed with H_2SO_4 .

Ammonia synthesis. H. HARTER. U. S. 1,550,806, Aug. 25. A mixt. of H and N under a pressure not exceeding 60 atm. is conducted through a plurality of contact chambers arranged in successive furnaces. The NH_3 formed in each contact chamber is removed from the gas mixt. before its entry into the next chamber (without replacing the quantity of gas mixt. transformed into NH_3).

Catalyst for ammonia synthesis. H. HARTER. U. S. 1,550,805, Aug. 25. Fe itself or other metal of the Fe group is smelted with an oxide of Mo, W, Ti, V, Th or Mg which is not easily reduced by H, and with a third substance for producing a glaze. Chamotte, kieselguhr or clay sand may be used as a carrier.

Oxidation of ammonia. C. ELLIS. U. S. 1,558,598, Oct. 27. A mixt. contg. NH_3 and air is passed in contact with a catalyzer contg. a metal of the Co group and an "acid-forming element which is capable of increasing its catalytic activity," e. g., V in the form of Co vanadate.

Calcining alkaline earth carbonates. H. MEHNER. U. S. 1,550,557, Aug. 18. In calcining $CaCO_3$ or similar materials, a charge is supported on a previous grate in the lower portion of a furnace-generator and relatively cool combustible gas and steam are admitted to a zone immediately above the charge. Air is admitted into an upper zone of the furnace-generator, this being a combustion zone where the combustible gas is burned and is sepd. from the charge by the intermediate layer of relatively cool combustible gas and steam through which heat radiates to the charge. Products dissociated from the charge are drawn off from a zone below the grate.

Sodium carbonate. G. N. LIBBY. U. S. 1,558,901, Oct. 27. In making Na_2CO_3 , finely divided MgO is added to a satd. soln. of trona.

Anhydrous magnesium chloride. P. COTTRINGER and W. R. COLLINGS. U. S. 1,557,660, Oct. 20. Partially dehydrated $MgCl_2$ is intermixed with the normal hydrated salt, both in solid form and the mixt. is then directly heated to drive off H_2O . A countercurrent of combustion gases may be used for the heating and dehydration.

Aluminium chloride. H. I. LEA and C. W. HUMPHREY. U. S. 1,558,897, Oct. 27. $Al_2(SO_4)_3$ is decomposed, e. g., by heating. The S oxides thus formed are used with Cl for the production of a chlorinating agent, and the latter is used for chlorinating the Al_2O_3 produced from the $Al_2(SO_4)_3$.

Titanium sulfate. H. N. McCOY. U. S. 1,559,113, Oct. 27. Sol. titanate sulfate is formed by reacting upon basic Ti sulfate with fuming sulfuric acid.

Zinc sulfide. G. DE HEDOUVILLE and P. PIPEREAU. U. S. 1,560,380, Nov. 3. In making crystd. ZnS , H_2S gas is caused to act on $ZnSO_4$ or other solid oxygenated compds. of Zn at temp. between 250° and redness.

Nitrogen oxides. H. G. A. RAMSAY. U. S. 1,558,046, Oct. 20. "Lime nitrogen" or other solid metallic CN compds. are burned in the presence of O air or O_2 at $850-950^\circ$ to produce N oxides.

Sulfur in allotropic form. H. H. WILKINSON. U. S. 1,560,926, Nov. 10. S is heated *in vacuo* in a still until it is liquefied and vapors are evolved. The vapors are then transferred (still *in vacuo* and assisted by a current of inert gas such as N, CO_2 or flue gas) into a vacuum receiver and condensed *in vacuo*. The product forms finely divided, deep yellow, highly purified, light weight, allotropic S of substantially equal sized particles and is free from SO_2 .

Stabilizing solutions containing "loosely-combined oxygen." V. WINTSCH, JR. U. S. 1,559,599, Nov. 3. A sol. "pyrophosphate salicylate" such as 1% of the Na compd. is used for stabilizing solns. of H_2O_2 , Na perborate or of similar compds. U. S. 1,559,600 also specifies the use of sol "pyrophosphate salicylate" (such as may be prepd. by heating Na pyrophosphate with salicylic acid) for the same purpose. The stabilized solns. of compds. thus prepd. are adapted for bleaching vegetable fibers, etc.

Apparatus for purifying talc, etc., by screening and action of suction air currents. G. F. HANNAM. U. S. 1,560,910, Nov. 10

Urea from calcium cyanamide. J. BRESLAUER and G. DARIER. U. S. 1,559,516, Oct. 27. Raw Ca cyanamide is introduced in small portions and in finely divided condition into H_2O maintained at a temp. of about $30-40^\circ$ to which there is also added an acid such as CO_2 which forms insol. salts with "metallic" impurities which are present in the cyanamide. The pptd. compds. are sepd. and the purified free cyanamide in the soln. is converted into urea by the action of H_2SO_4 and heating to $60-70^\circ$. U. S. 1,559,517 specifies converting free cyanamide into urea by the action of an acid salt such as an acid phosphate. U. S. 1,559,518 specifies adding finely divided successive portions of raw Ca cyanamide to H_2O acidified with an acid substance such as acid phosphate which will ppt. metallic constituents of the raw material, while agitating the aqueous liquid. After removal of the insol. salts formed from the resulting soln. of free cyanamide, the latter is treated with an acid sulfate, e. g., $NaHSO_4$, and heated to about $60-70^\circ$ to hydrate the free cyanamide in soln. to urea.

Hydrated alumina. G. L. WILLIAMS. U. S. 1,559,489, Oct. 27. Hydrated alumina in granular form is obtained by pptg. a soln. of K aluminate with boiler furnace gases.

Dry composition for producing iodine. W. C. MOORE. U. S. 1,557,266, Oct. 13. A dry mixt. for producing free I on contact with H_2O comprises KI, KIO_3 , partially dehydrated cryst. $Al_2(SO_4)_3$ and KCl or similarly constituted and reactive materials.

Moldable composition containing phenolic condensation product. E. E. NOVOTNY and C. J. ROMIEUX. U. S. 1,557,318, Oct. 13. Paper, cloth, asbestos or other fibrous filler together with lanolin is used with a binder of phenolic condensation product for forming sheets or other molded articles.

Decolorizing material. P. L. WOOSTER. U. S. 1,558,137, Oct. 20. The C is removed from bone char by heating and the material is then exposed to vapors arising from heating or incomplete combustion of bitumen or other hydrocarbon material. The product is adapted for treating sugar solns., etc.

Active charcoal. H. THIENEMANN. U. S. 1,551,074, Aug. 25. A paste of finely ground peat and a soln. of $FeCl_3$ or other suitable substance "contg. an inorg. acid radical" is formed into compact bodies, dried and calcined. U. S. 1,551,075 specifies heating H_3PO_4 and finely ground brown coal.

Recovering diatomaceous earth after use for clarifying sugar solutions or for similar purposes. R. C. WILLIAMS. U. S. 1,561,042, Nov. 10. "Mud-cake" such as is left after treating sugar solns. is used for making bricks, tiles, heat insulation or other molded

articles after a preliminary treatment, *e. g.*, either a preliminary fermentation or admixture with a germicide to prevent disruptive fermentation in the molded article.

Molded articles from casein "artificial horn." A. BARTELS and O. MIECH. U. S. 1,560,368, Nov. 3. A prep'd. comparatively firm casein mass is passed through an extrusion app., molded under yielding pressure and the formed articles are then hardened and dried.

Adhesive from starch. H. V. DUNHAM. U. S. 1,551,472, Aug. 25. Starch is treated with saccharate of Sr or other saccharate of an alkali-forming metal and heated with H₂O to at least the bursting temp. of the starch granules.

Absorptive carbon. A. W. SMITH. U. S. 1,559,054, Oct. 27. Fibrous vegetable material such as sawdust treated with molasses is charged after impregnation with metallic compds. such as Ni(NO₃)₂ and the metal is then reduced to elemental form in the material, *e. g.*, by heating and treating with H. The product is adapted for use in decolorizing sugar solns., oils, etc.

Hydrating lime. D. R. BONE, SR. U. S. 1,556,670, Oct. 13. Lump lime is placed on a screen-bottom car, the car is dipped in H₂O and then drained of excess H₂O.

Foam for extinguishing fires. G. J. ESSELEN, JR. U. S. 1,558,599, Oct. 27. The residue of neutralized and evap'd. sulfite waste liquor is used as a foam-maintaining and evapn.-preventing material.

Sealing composition containing sulfur and fibrous material. F. A. ADAMSKI. U. S. 1,557,231, Oct. 13. A compn. adapted for *sealing dry cell elec. batteries*, etc., comprises S mixed with asbestos or other fibrous material and an inert granular material such as sand.

Cement containing resin and rubber. W. M. MARLETT. U. S. 1,561,095, Nov. 10. A cement adapted for *fastening rubber tires to wheels* is formed from resin 3.75, coal tar pitch 1, linseed oil 0.25, vulcanized rubber 1.5 and sufficient gasoline (about 1.5 parts) to bring the mixt. to the consistency of heavy molasses.

Friction facings for brakes and clutches. I. J. NOVAK. U. S. 1,551,045, Aug. 25. Asbestos fiber is sheeted on a paper machine, calendered to the desired thickness, formed into friction facings and sat'd. with a "topped crude oil" having an asphaltic base, and then heated to harden the binder.

Heat-generating composition. J. M. DENNISON. U. S. 1,558,248, Oct. 20. A compn. adapted for producing heat on adding H₂O is formed from oxidized Fe filings 100, NH₄Cl 2, CaO 4, and H₂SO₄ 6 parts.

Sound records. F. W. JONES, JR. U. S. 1,558,175, Oct. 20. Disk records are formed under pressure from one or more porous disks of a thermoplastic material such as a compn. contg. cellulose acetate, a gelatinizer, acaroid resin, barytes, SiO₂ and vegetable black.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Suitability of certain Nyasaland clays for the manufacture of bricks, tiles, drain-pipes and pottery. ANON. *Bull. Imp. Inst.* 23, 281-91 (1925).—A sample described as "marl," stated to occur on the Tangasi River, southwest of Chiromo, as part of the shale series of the local coal measures, was found suitable for use in the manuf. of building bricks, roofing tiles and unglazed drain-pipes. A sample described as "superficial clay from the roadside opposite Mission Garden, Vungu Vungu Valley" was found unsuitable for the manuf. of bricks, tiles or drain-pipes. "Karoo clay from the crossroads, Manchewe Valley," mixed with sand (70 clay to 30 sand) (through a 50-mesh sieve for pipes and through 20-mesh sieve for bricks and tiles), gave bricks suitable for ordinary building purposes, satisfactory drain-pipes, and tiles which were much weaker than ordinary com. tiles, but which would probably be suitable for local use. "Karoo clay from white clay pit, mission brickfield" could be used for the manuf. of rough pots, plates, cups, etc., by suitable firing (1050° for 6 hrs. and 1120° for 2 hrs.), and could be glazed either by dusting the unfired ware when damp with siliceous galena and firing at about 1000-50°, or preferably by moistening the ware (fired at not less than 1050°) with a slightly adhesive comp'd. (dild. gum or molasses) and then dusting with galena and refiring to about 950°.

Dolomites and magnesite. J. DAUTREBANDE. *Rev. chim. ind.* 34, 246-9, 276-7 (1925).—Brief review of their properties and uses.

A. PAPINEAU-COUTURE

A. PAPINEAU-COUTURE

Artificial magnesia from dolomite. G. D. *Rev. chim. ind.* **34**, 278-81(1925).—Brief outline of some of the more important processes proposed for production of practically CaO-free MgO.

Optical method of determining the fusion points of refractories. ENRIQUE HAUSER. *Rev. mat. constr. trav. pub.* **190**, 159-61B(1925).—By the use of a Féry optical pyrometer H. detd. the fusion points of numerous refractories. The pyrometer was sighted on the end of a molded test piece, through an opening in a wall to minimize the extraneous light. The heating was accomplished by means of an oxy-hydrogen flame. Seger cones heated at the base melted at temps. to within 10° to 20° of their rating. The method is not adaptable for the m. p. detns. of oxidizable metals. L. NAVIAS

Etching and staining process for testing refractory materials. E. STEINHOFF AND F. HARTMANN. *Stahl. u. Eisen* **45**, 337-43(1925).—The etching and staining process, well known in petrological practice, has been applied to the testing of refractories (cf. Scott, *Trans. Geol. Soc. Glasgow* **16**, 393-414(1918)). The etching soln. consists of equal parts of concd. HCl and satd. AlCl_3 soln. The gelatinized ingredients are stained by the action of a concd. soln. of methylene blue. For the detn. of structural ingredients contg. lime, anthrapurpurin is used as the staining medium. In this case, the staining action does not represent an adsorption process; hence, etching is not essential. The success of the method depends upon the selective staining of the individual components. E. g., clay fired at, or below, 1000° is stained a deep blue; fired at 1100° it is stained light blue; fired at 1200° it is scarcely colored, and fired at 1300° it remains colorless. Unmodified quartz is colorless under the treatment, while modified quartz is stained sky blue. Differentiation is also effected between the various "contact zones," e. g., clay-lime, clay-magnesia, clay-iron oxide, quartz-clay and quartz-iron oxide. Both the clay-lime and the clay-magnesia contact zones are stained dark blue by methylene blue, but they are distinguishable when treated with anthrapurpurin, which gives a typical reddish brown color with ingredients contg. lime. Examples of the practical application of the method are given. The complete test supplies data on the following: the firing temp. of fired clays and the amt. of undesirable impurities present; the firing temp. of fireclay-grog bricks, the occurrence and distribution of quartz and localized lime and magnesia fusions, and the degree of modification of the quartz; the presence and position of thin layers of kaolin in quartzites, and the progress and type of the quartz modification; the extent of the quartz modification in silica bricks, and the behavior of the silicate fusions.

B. C. A.

Refractories for water gas sets (RUSSEL) 21.

Glass resistant to sudden temperature changes. V. HORAK. U. S. 1,557,540, Oct. 13. In making a glass which will stand a sudden fall of temp. from 320° to 0° , a batch is melted (at about 1200°) which is formed from sand 60-70, H_2BO_3 15-30, K_2CO_3 1-2, Na_2CO_3 3-6, kaolin 2-6, muscovite 1-4, ZrO_2 1-3 and TiO_2 1-3%.

Variegated glass. I. H. FREESE. U. S. 1,529,947, March 17, 1925. Streams of molten glass of different colors are united by enveloping one of the streams within the other, the glass being then molded into marbles or other articles.

Etching glass. C. C. MINTER. U. S. 1,556,796, Oct. 13. Na_2CO_3 or other alkali carbonate is heated to at least its fusion point and then brought into contact with a glass surface to be etched.

Mold for glass. F. J. FRINK and R. L. FRINK. U. S. 1,556,925, Oct. 13. Molds formed of Al-Ca, Al-Ba, Al-Mg (or of similar metal alloys contg. Cu instead of Al) have vascular or pitted inner surfaces which are formed by the action of an alk. metal hydroxide. By treating such molds with H_2O before use, need of coating compns. is avoided.

Reinforced glass sheets. G. B. RILEY. U. S. 1,560,321, Nov. 3. Glass sheets to be cemented to opposite sides of a sheet of celluloid are preliminarily treated with a soln. of "isinglass" and dextrin gum. The sheet of celluloid is treated with a soln. of colophony and castor oil and the glass and celluloid are united under the action of heat and pressure.

Metallizing porcelain or glass. A. F. RIJSEN. U. S. 1,558,853, Oct. 27. A dull surface is rubbed with a very small quantity of a viscous polyvalent alc. such as glycerol by use of a metal brush (e. g., a brass brush); a further coating of metal, e. g., Cu, is then deposited electrolytically.

Leer for annealing glassware. V. MULHOLLAND. U. S. 1,560,481, Nov. 3.

Glass-melting furnace. W. A. YUNG. U. S. 1,561,393, Nov. 10.

Glass-melting tank-furnace. T. C. MOORSHEAD. U. S. 1,557,078, Oct. 13.

Ceramic materials. H. SPURRIER. U. S. 1,559,652, Nov. 3. Gases are evacuated from ceramic materials such as those for making crucibles, pottery, tile or spark plugs, and after this the vacuum is suddenly broken in order to render the material compact.

Refractory articles. S. A. MYLER. U. S. 1,559,275, Oct. 27. Molds, crucibles, bricks, electrodes or other refractory articles are formed by mixing graphite and pulverized coal with petroleum oil to form a putty-like mixt., molding and heating until the oil is dried from the compn., then dipping in tar and completely carbonizing the product.

Basic refractory material. K. P. McELROY. U. S. 1,551,201, Aug. 25. Granular fragments of shrunk, burnt dolomite are provided with an exterior coating of less refractory dolomite material, *e. g.*, dolomite fines.

Baking enamels. T. E. THOMPSON. U. S. 1,558,517, Oct. 27. Powdered fused enamel is applied to automobile bodies or other articles to be coated together with a fluid vehicle such as linseed oil or varnish which leaves a binding residue, and the coated articles are then baked at a temp. below the fusion point of the enamel.

Frit kiln. F. P. VOGEL. U. S. 1,550,474, Aug. 18.

Tunnel oven or kiln. H. FRANCART. U. S. 1,557,040, Oct. 13.

Casting and shaping fused quartz. H. A. WAYRINGER. U. S. 1,551,351, Aug. 25. Mech. features.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

The occurrence of iodine in cement flue dust. E. KEYSNER. *Chem.-Ztg.* **49**, 821(1925).—An examn of cement flue dust showed the presence of 50 mg. I per kg. In contradistinction to the accepted view that I gets into the dust from traces of the element present in the limestone used, it is shown that the fuel may supply I. Coal contg. only 0.000092 g. I per kg. may yield a soot running 0.038 g. I per kg. W. C. E.

The movement of materials in industrial plants. V. BEZOLD. *Chem.-Ztg.* **49**, 833-4(1925).—An elementary presentation of the theory and practice of conveyor systems. W. C. EBAUGH

Calcium sulfate retarders for portland cement. E. E. BERGER. *Rock Products* **28**, No. 22, 56-9; Bur. Mines, *Repts. of Investigations* No. 2705, 20 pp (1925).—Plaster of Paris, gypsum and anhydrite alone and in mixts. were tested in the lab. Plaster is the most efficient retarder and is necessary for quick setting clinker, but does not control plasticity satisfactorily. Mixts. of plaster with gypsum or anhydrite produce more satisfactory cement than plaster alone provided there is enough plaster to retard the set. In com. practice, some of the gypsum is probably calcined to plaster in the tube mill. A series of mill tests is recommended. RAYMOND WILSON

Effect of storage of calcined gypsum on linear expansion of plaster. L. E. SMITH. *Rock Products* **28**, No. 20, 54-6(1925).—Freshly calcined gypsum hydrates gradually on exposure to air. Test specimens made from calcined gypsum which had been exposed to the air for 6 months showed greater changes in vol. due to humidity changes than specimens made from freshly calcined gypsum. RAYMOND WILSON

The use of tar in highway surfacing. HANS LÜER. *Gas u. Wasserfach.* **68**, 635-6(1925).—A brief economic discussion, recommended specifications being cited. WM. B. PLUMMER

Paving material. D. V. SNOWGOOSE. U. S. 1,551,065, Aug. 25. Pulverized asphalt rock is heated to remove the light oils from it and then mixed with 10-20% as much hard asphalt while heated.

Colored concrete mixture. J. J. CONNELLY. U. S. 1,556,759, Oct. 13. A dried pulverized product formed from a semi-pulpy mixt. of wood, paper and a mineral pigment, a crushed clay product (hardened by burning and similarly colored) and a cement, *e. g.*, a lime or magnesia cement, is adapted for making flower pots, pottery, etc.

Electrolytic coating of roofing materials. J. H. GILLIS. U. S. 1,559,040-1, Oct. 27. Mech. and elec. features of coating roofing felt with Cu or similar coating operations.

Apparatus (burning powdered fuel) for production of cement clinker. T. FUJIIYAMA. U. S. 1,561,070, Nov. 10.

Rotary kiln adapted for heating cement-forming mixtures. M. VOGEL-JØRGENSEN. U. S. 1,557,475, Oct. 13.

Plastic composition. M. BROJNICK. U. S. 1,556,641, Oct. 13. A mixt. adapted for making plaster board, veneer cores, etc., is formed of corn and similar stalks 25, reduced to a pulp with an alkali, e. g., K_2CO_3 2 and an adhesive such as flour paste 5 parts.

Treating roads. T. J. A. JACOMET. U. S. 1,558,172, Oct. 20. The residue from alc. distn. is applied to roads to render them "dust-free."

Preserving wood. J. H. JAMES. U. S. 1,561,164, Nov. 10. A wood preservative contg. alcs., aldehydes and aldehyde fatty acids is prepd. by the partial oxidation of petroleum hydrocarbons, e. g., by passing petroleum oil vapor and air over blue oxides of Mo at 200–500°, with or without steam.

Impregnating wood with preservatives or coloring substances. C. SCHANTZ. U. S. 1,550,395, Aug. 18. Wood or similar material capable of being distd. by moisture is treated with steam or vapor of a volatile org. substance such as a hydrocarbon, alc. or CCl_4 , admixed with cresol or other homolog of phenol, in order to shorten the time required for the treatment.

Impregnating wood with montan wax. J. R. COOLIDGE, 3RD. U. S. 1,556,570, Oct. 6.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Recent developments in fuel technology. R. WIGGINTON. *Fuel in Science and Practice* 4, 371–2, 417–9, 461–2 (1925), cf. C. A. 19, 3361—Brief reviews in abstract form C. C. D.

Physico-chemical investigation of four liquid fuels prepared from primary tar obtained from waste products of the Saar mines. Introduction. J. SAINTE-CLAIRE DEVILLE. *Chaleur et industrie* 6, 311–2 (1925).—Hand sorted shale (55–65% ash) was distd. in a semi-con. rotary retort, the products of distn. leaving the retort at 300–430°. H_2O and light spirit were removed from the tar by heating 30 kg. of the latter for 15 hrs. at 120° while coal gas was passed through the charge. The "crude spirit" thus obtained (6–10% of the tar) is washed with NaOH, H_2SO_4 and H_2O and the residual oil rectified into 3 fractions: 65–130° (fuel I), 130–50° (fuel II), 150–80° or 200° (fuel III), which were clarified by filtration through calcined bauxite. "Medium phenol oil" is obtained from the dehydrated tar by gradually heating to 180°, washing the oil with H_2SO_4 and NaOH (loss of nearly 50%) and filtering through calcined bauxite, giving fuel IV. Purification by rectification is useless because the oil could not bear the cost and is too liable to cracking. **Investigation of the liquid fuels obtained from the tar.** M. AUBERT AND R. MOUTTE. *Ibid* 312–9, 373–9, 429–31.—Very detailed results are given of the investigation of the phys., optical and thermodynamical properties and of the compn. of fuels I, II, III and IV, for which the original article should be consulted. **Motor tests of liquid fuels obtained from low-temperature carbonization of coal.** KRAKOWSKY, ELOY, SCHREINER AND J. SAINTE-CLAIRE DEVILLE. *Ibid* 431–3.—Tests carried out with a Deutz locomotive with a one-cylinder engine showed that addn. of 10–20% of fuel IV to benzene caused no trouble, required no change in the adjustment of the motor and (with the higher proportions of fuel IV) developed more power than with benzene alone. With better rectification (e. g., in a con. distg. column) up to 30% could probably be used. Tests carried out on an automobile engine showed that fuel I can be mixed in all proportions with the usual motor fuels and can even be used alone without requiring any change in the motor; and that fuel II cannot be used alone, but can be mixed up to 20–5% with the ordinary motor fuels.

A. PAPINEAU-COUTURE

Tests for fuels for aircraft by Navy Bureau of Aeronautics. E. E. WILSON. *Oil & Gas J.* 24, No. 9, 110 (1925).—The Bur. of Aeronautics has tested fuels which are at numerous points available and which meet the requirements of high compression (5 to 1) in order to develop a fuel which will permit better performance on decreased weight. It has been shown that Stellarine and cyclo gas can be successfully used while Ethyl Fluid constitutes the only material which meets all the requirements. Two innovations, a new spark plug, and variation of spark advance under throttled conditions have also been developed.

M. B. HART

Fuel charge mixing and flame propagation. A. H. DENISON. *J. Soc. Autom. Eng.* 17, 273 (1925).—The fuels studied were distillates 32–36° Bc. fuel oil, 40–41° fuel oil, an unrefined kerosene, a 58° gasoline with from 25 to 27% benzene added and a 68–70° straight-run gasoline. Two engines of special and similar design were used,

air and fuel being mixed previously to ignition, without preheating. Conclusions reached are that the rate of flame propagation through an optimum fuel-air mixt. varies (a) probably directly with the phys. mixt. condition at the time of ignition; (b) very slowly within certain limits with different grades of fuel and (c) very slowly with the condition of the fuel at the moment of ignition; (d) with different compression pressures it varies in an undefined manner; (e) very much higher rates of flame propagation than are being obtained in present engines seem to be an inherent property of common fuels. Detonation may be due to further phys. mixing of fuel and air by pressure and flame waves set up during the first burning period which may cause another cycle or a chem. transformation similar to cracking may occur, causing a new mixt. condition.

M. B. HART

Processes for the production of light oils for internal-combustion engines. M. BRUTZKUS. *Chimie et industrie* 14, 171-85, 358-62(1925).—van't Hoff's equation, $d(\ln K)/dT = Q/TR^2$, is expressed as follows: "Any chem. reaction can be directed and accelerated in a certain direction by continuous and simultaneous external variations in pressure, temp. and concn., acting in a direction contrary to that of the corresponding variations caused by the desired reaction." B. suggests that the desired variations in pressure, temp. and concn. can easily be obtained by operating in a compressor constructed and operated substantially as a Diesel engine. The application of such a method for cracking or hydrogenation under various conditions (exothermic and endothermic reactions), for the treatment of petroleum, tar oils, turpentine, fats, sugars and molasses, cellulose compds., and coal and for the synthesis of light oil from CO, CO₂ and H₂ is discussed, and compared with corresponding processes at present in use or proposed. Very high temps. and pressure could be used and catalyzers could be eliminated.

A. PAPINEAU-COUTURE

Valuable fuel from wood. ANON. *Allgem. Österr. Chem. Tech. Ztg.* 43, 115-6(1925).—A résumé of the present method of wood carbonization is given. A new app. is described whereby wood is lowered into a shaft while indifferent heating gases are passed through upwardly. The wood is first dried, then the gas is extd. and finally the ordinary charcoal is hardened by a special process. Such an invention is of great importance to Europe as it, together with the proposed charcoal generator for automobiles, will eliminate present dependence on imported motor fuels. M. B. H.

Fuel of high calorific value from wood. STRACHE. *Allgem. Oesterr. Chem. Tech Zte* 43, 115(1925).—The new method of making charcoal of greater hardness than usual is described. Wood waste is heated by gases in a retort. The gases do not contain any O and are brought in direct contact with the wood. The charcoal so obtained is called "Lignizik." The by-products are recovered and the charcoal so obtained is harder than usual and has more applications and uses.

M. B. HART

A new procedure for obtaining raw peat and its manufacture into briquets with recovery of by-products. RUDOLF SCHADE. *Z. tech. Biol.* 11, 129-34(1925).

H. J. DEUEL, JR.

Bitumen and bituminous coal. Definitions. E. R. FRANZ. *Fuel in Science and Practice* 4, 494-7(1925).—A compilation of definitions from various standard dictionaries, encyclopedias, textbooks and original articles.

C. C. DAVIS

Rapid determination of the strength of brown coal briquets. RUDOLF JACOB. *Braunkohle* 24, 636-8(1925).—A rapid graphical method for taking into account the variations in size of briquets in calcg. the strength from the breaking load is given (for method of testing cf. Hentze, C. A. 19, 1936).

W. B. P.

Changes in brown coal deposits formed in contact with basalt. H. WINTER. *Braunkohle* 24, 653-8(1925).—Proximate and ultimate analyses of various types of brown coal are given which presumptively show the catalytic effect of the basalt on the coal.

WM. B. PLUMMER

The conversion of coal into oil by hydrogenation. J. I. GRAHAM. *Colliery Guardian* 130, 973-5(1925).—A review of systematic work on the action on coal of H up to 200 atm. at 300-450°, the greater part of which has already been published (cf. C. A. 19, 1188, 1767). In a study in progress on the action of high-pressure steam on coal to det. the temp. at which coal dust reacts with H₂O, coal was ground in a colloid mill fine enough for a suspension in H₂O still to contain 30 g. per 100 cc. after some days.

C. C. DAVIS

Low-temperature carbonization of coal. (I) Treatment of coal at 500° in Fischer's aluminium retort. AKIRA SHIMOMURA. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8, 397-411(1925).—The standard Al retort and accessory app. as described by Fischer (C. A. 15, 8149) was used, with 20 g. air-dried coal ground to pass 0.25 mm., the temp. in the retort being brought to 500° in 45 min. and held there 45 min. Results are given for 15

oriental coals ranging from bituminous to anthracite, of which the following are typical (the properties and results are given in the order of the various coals as named; all data are on air-dried samples) Koyaki (Japan), Sakito (Japan), Nansu (Sumatra), Matsushima (Japan), Kaiping (China), Poshan (China), Rogaty (Sakhalin), Tsun-Chin (China), Mallien (India). *Coal analyses*.—% Moisture, 1.52, 1.54, 3.42, 2.26, 1.42, 0.74, 1.32, 1.84, 3.99; % volatile combustible matter 38.24, 36.66, 32.72, 32.81, 27.10, 21.58, 18.98, 8.59, 3.41; % ash, 8.65, 11.95, 4.03, 12.34, 13.24, 11.30, 9.40, 11.63, 15.95; % fixed C, 51.47, 49.85, 59.83, 52.59, 58.24, 66.39, 70.23, 77.94, 76.65; % S, 0.78, 2.03, 0.61, 1.42, 0.95, 0.61, 0.46, 0.67, 0.83; % N, 1.64, 1.15, 1.35, 1.33, 1.16, 1.44, 1.69, 1.49, 0.66; (the % C and % H are also given). *Carbonization yields*.—% Tar, 15.28, 17.42, 11.48, 15.22, 11.35, 6.85, 5.97, 0.64, 0.55; % NH_3 (as such), 0.0558, 0.0324, 0.0315, 0.0388, 0.0233, 0.0244, 0.0333, 0.0596, 0.0118; gas, cc./g., (at normal temp. and pressure), 68.6, 56.7, 68.6, 63.7, 51.7, 52.2, 60.2, 12.0, 0.0; % volatile matter of semi-coke, 11.33, 11.60, 11.17, 10.50, 10.85, 9.30, 9.35, 6.60, 2.58, other data are given, including gas analyses and ultimate analyses of the semi-coke. The character of the semi-coke was of 4 types; swollen, spongy and fragile, Sakito and Poshan; swollen and spongy but of hard, firm structure, Koyaki and Kaiping; dense and firm but little swollen, Matsushima and Rogaty; non-coherent and powdery, Nansu, Tsun-Chin and Mallien.

WM. B. PLUMMER

The liquefaction of wood and cellulose and some general remarks on the liquefaction of coal. H. E. FIERZ-DAVID. *Chemistry & Industry* 44, 942-4 (1925). Attempts to prep. liquid fuel by the Bergius process yielded disappointing results. When cotton cellulose was treated with $\text{Ni}(\text{OH})_2$, dried and heated to 450–70° under 150–220 atm. of H, almost all of the cellulose distilled over as a yellow liquid, η_{20} 1.017, contg. aldehydes, ketones, phenols, alkylfurans, and fatty acids, with a calorific value of 9275 cal. F. Fischer has shown that CO and H under 100 atm. and 410°, in the presence of Fe and alkali carbonate, form liquid fuels, b. 80–250°. T. S. CARSWELL.

Enrichment of coal gas by the injection of oil into the retorts during carbonization. ANON. (Dept. Sci. & Ind. Research) *Fuel Res. Bd. Tech. Paper No. 14*, 61 pp (1925).—Steaming in ams. up to 20% by wt. of the coal in continuous vertical retorts of the Glover-West type has been found previously (*C. A.* 17, 3088; 18, 319) to give high gas making efficiency and increased by-product recovery, but at the expense of a decrease in the calorific value of the gas, so that the addn. of carburetted water gas is necessary to maintain a standard B. t. u./cu. ft. value. To avoid additional plant investment and operating expense for carbureters was the object of the present expts. The oil was injected through a small pipe protected by a 2.5 in. water jacket and inserted vertically down the center of the retort, the open end of the pipe being 10.5–12.5 ft. down from the top, deeper immersion forming undue ams. of H_2 , less immersion not giving complete fixation of the oil. Tests were carried out on Wearmouth and Mitchell Main coals, of which the latter results only will be cited here; this latter coal had 1.5% moisture, 32.5% volatile combustible matter, 60.7% fixed C, 5.3% ash. A light gas oil was used, the efficiency of cracking (increase in total B. t. u. in gas/B. t. u. in oil used) was 76%; when 4.8 gal./ton coal and 53% at 9.4 gal./ton were used. The presence of the water-cooled tube alone caused a loss of 450 cu. ft./ton but increased the B. t. u./cu. ft. from 518 to 529, or a net loss of 0.67 therms./ton in the gas (therm = 100,000 B. t. u.); both of these effects are due to the lowered center temp. and decreased cracking. A large no. of tests covering various pipe positions, oil and steam rates, etc., are reported in detail. The final "com. tests" were so arranged as to give a constant B. t. u. gas at various loads; the carbonizing temp. was 1200°, the coal rate 2.5 tons/retort/24 hrs., steady state being maintained 72 hrs. in each test. *Blank test*, injection tubes not in position, 5.05% steam used; *min. load*, injection tubes in position, no oil used, 8.51% steam; *mean load*, 4.83 gal. oil/ton, 11.95% steam; *max. load*, 7.13 gal. oil/ton, 20.14% steam. Results, in the order given, were as follows: gas B. t. u./cu. ft., 518, 522, 525, 520; gas yield, cu. ft./ton, 15,600, 16,270, 17,370, 18,180; gas yield, as % increase over blank test, —, 4.3, 11.3, 16.9; fuel gas used/retort/hr., therms, 15.2, 15.8, 16.4, 16.9. The process is evidently a com. possibility. Further expts. are being carried out on dropping the oil down the center of a vertical pipe having no cooling system, so as to avoid the cooling water losses of the present method, preliminary work indicating the possibility of such injection. Results are also given for normal steaming tests, lab. retort assays, etc., for the coals mentioned. Analyses of coal, coke, (fuel, flue and make) gas, temps. and pressures within the retorts, etc., are given in detail for all tests reported. W. B. P.

Technical advances of gas. ANON. *Gas u. Wasserfach* 68, 623–5, 636–9 (1925).—Brief description with sketches or photographs of numerous improved burners, furnaces and furnace installations, temp. controllers, etc. WM. B. PLUMMER

The relation between heating value of gas and its usefulness to the consumer. E. R. WEAVER. *Bur Standards, Tech. Paper No. 290*, 347-463 (1925).—A critical review of available data regarding the relative usefulness of gases of different heating values, the data being divided into 2 classes, *viz.*, (a) the direct detn of useful effects actually obtained by burning gas in various appliances and (b) statistics regarding the relative quantities of gas used by various consumers or in various communities before and after changes in the heating value. The data of both classes are quite consistent, leading in each case to the conclusion that the usefulness to the consumer of a given vol. of gas is accurately proportional to its heating value. Results of tests, statistics and critical discussions from all available sources are given in detail with many curves, etc., and are individually and collectively discussed. WM. B. PLUMMER

Gas heating value as a measure of usefulness. KURT BLUME. *Gas u. Wasserfack* **68**, 675-8 (1925).—Recent discussion in the U. S. is cited, and it is pointed out that in many German cities the cost of gas per B. t. u. is 100% over pre-war figures, caused by the use of mixed gas at an increased price per unit volume. Theoretical flame temps for a (mineral or bituminous) coal gas is calcd as 1737°, for a mixed gas contg. 23.9% water gas 1757°, for one contg. 12.8% producer gas 1720°, the heating value of the former being 4640 kg. cal./cu. m., of the 2 latter each 4200. The conclusion drawn is that the decrease in heating value is not compensated for by the change in flame temp. WM. B. PLUMMER

The industrial importance of the natural gas of Roumania. P. STÄHELIN. *Monit. petrole Roumain* **24**, 971-6 (1925).—Transylvanian natural gas contains 98-99.5% methane. Data are given showing the compn. of various gaseous fuels together with their ds. and calorific value. Acetylene has a max. of 13,800 cal. per cu. m.; natural gas (Transylvania) 9500 cal. per cu. m. M. B. HART

The increase of sulfur in gas during benzene washing. FRITZ WEHRMANN. *Gas u. Wasserfack* **68**, 658-9 (1925).—Fresh wash oil contg. 0.67% total S, in a lab. expt., lost S to gas bubbled through it at such rate as to increase the S of the gas by 0.0003%, but a sample of recovered wash oil (light oil distn. residue) contg. 2.24% total S showed a much higher rate of loss. Gas contg. no H₂S may pick up enough to darken Pb(OAc)₂ paper during passage through benzene scrubbers, but the increase will not be of any importance unless the total S of the wash oil exceeds 1.0%. WM. B. PLUMMER

Helium in natural gas from oil wells. J. CLAY. *Proc. Acad. Sci. Amsterdam* **28**, 529-30 (1925).—See C. A. **19**, 3234. E. J. C.

The back-run process (for water gas. Report of sub-committee). A. H. ANDERSON. *Proc. Am. Gas Assoc.* **1925** (advance copy), 14 pp. Operating results are tabulated in detail for plants using back-run operation, 15 of them using coke fuel, 13 using anthracite, bituminous, or mixts. of these with coke. Considerable gains in capacity and fuel and oil efficiencies are reported by some operators, while others report but slight gains, and in some cases even losses; the results cannot therefore be summarized but must be examined individually. Operating conditions with respect to clinkering and cleaning labor were either unchanged or improved; the life of checkers was increased in most cases. WM. B. PLUMMER

Modification of water gas sets for the use of heavy oil. W. D. STEWART. *Proc. Am. Gas Assoc.* **1925** (advance copy), 1 p.; cf. C. A. **19**, 2404.—Operating results are given for the modified set as previously described. The oil used was Mexican fuel, 0.9776 sp. gr. or 13.3 Bé., having a coke residue of 16.9% and S content of 4.7%. Results were coke fuel 31.0 lbs./1000 cu. ft. gas, oil 3.6 gals./1000 cu. ft. gas, gas B. t. u. 535, oil efficiency 86.5 B. t. u./gal., H₂S in gas 520 grains/100 cu. ft., fixed S in gas 40 grains/100 cu. ft., steam from waste heat boiler 75 lbs./1000 cu. ft., life of checker brick 1000 hrs. The fuel used was run-of-retort coke contg. all breeze made. WM. B. PLUMMER

The use of Illinois coal with the pier process (for water gas). M. P. NOVAK. *Proc. Am. Gas Assoc.* **1925** (advance copy), 8 pp. —Results with standard water gas sets using bituminous coal have shown the activity of the fire to be concentrated around the edge, with resultant inefficiencies. The present process eliminates the inactive central portion of the fuel bed by placing a refractory pier at the center of the grate, and extending up to about 1-2 ft. below the top of the fuel. In a 9 ft. inside diameter shell the pier is 2.75 ft. outside diameter, tapering somewhat at the top; it may be hollow and cooled by passing the air-steam blast up a pipe centered in the pier, then down, and up under the grate, but solid piers are apparently as satisfactory if properly constructed. Although the grate area is thus reduced 11.1% the gas-making capacity was increased 62% with a saving in fuel of 10-13%, due to the smoother operation of the set; other advantages are the saving in oil, decrease in blown-over fuel, and uniformity

of clinker formation with consequent reduction of clinkering time by 30–40%. Operating results are tabulated for several coals, of which the following are typical. Standard 11 ft. sets (9 ft. inside diam.), operating on a 5.5 min. cycle, 35% blow, 65% run (49% down run), air purge 17 sec., blow run on cycle 17 sec., 2 min. blow run after cooling, 2 straight runs after cooling, the rest split; coaling 3200–4500 lbs., every 7–9 runs. Using unscreened 1 25 in. Indiana lump coal, without and with pier, resp., the operating results of a 4 day (4 sets) test were as follows: 1000 cu. ft. gas make/set/day, 1158, 1877; blown over fuel lbs./1000 cu. ft. gas, 3.80, 1.64; net fuel used, lbs./1000 cu. ft. gas, 49.69, 44.89; oil, gals./1000 cu. ft. gas, 3.52, 3.59; gas, B. t. u./cu. ft., 551.551.

WM. B. PLUMMER

The use of bituminous coal (as water gas generator fuel) —results at various plants. W. G. RUDD. *Proc. Am. Gas Assoc.* 1925 (advance copy), 5 pp.; cf. *C. A.* 19, 2399, 2400 — Operating results for 6 plants using 40–100% coal are tabulated in some detail. The decrease in fuel efficiency in most cases was slight at mixtures around 80% and not serious even at 100% coal.

WM. B. PLUMMER

Gas analyses with mixtures of soft coal and coke in the water gas process. L. J. WILLIEN. *Proc. Am. Gas Assoc.* 1925 (advance copy), 1 p. — Average analyses for finished gas using 0, 40, 43 and 48% coal, with 10 sec. and 15 sec. blow runs in the last 2 cases, resp., show slight increases in inerts, CO₂ and illuminants. Analyses of samples from the top of the washbox during each run between coalings, using 100% coal, show max. CH₄ and min. CO in the 2nd run after coaling, and max. illuminants in the 3rd run, no blow run gas being included in the samples.

WM. B. PLUMMER

Non-clinkering gas generators. ANON. *J. usines gaz* 49, 299–301 (1925). — A brief description, with sketches and a résumé of operating data, of a battery of 6 producers having water cooled shells as installed by the Seaboard Co. at their plant "near New York."

WM. B. PLUMMER

The use of oxygen in water gas machines. A. C. FREY. *Proc. Am. Gas Assoc.* 1925 (advance copy), 9 pp. — Mainly a description and discussion of the Jeffries Norton process for O₂ manuf. using the principle of rectification of liquid air under high pressure and expansion from the still in engines having thermally insulated cylinders. It is estimated that by this process O₂ can be produced at 10 cents/1000 cu. ft. by a plant having a capacity of 2000 cu. ft./min., the cost increasing up to 50 cents for a 100 cu. ft./min. plant. Tests on oil gas production (in a model Dayton Oil Gas Furnace) showed an av. thermal efficiency of 71.5% (due to limited O₂ supply the test was stopped after 1.75 hrs. at which time the thermal efficiency was 88%); other data for the test were gas made/hr., 1730 cu. ft.; oil/1000 cu. ft., 5.47 gals.; O₂/1000 cu. ft., 235 cu. ft.; gas B. t. u. 543; gas analysis, av. of 2 samples, CO₂ 6.7, illuminants 6.05, O₂ 0.65, CO 42.5, H₂ 23.45, CH₄ 18.90, N₂ 1.75%, S 9.35 grains/100 cu. ft. WM. B. P.

Refractories (for water gas sets). W. M. RUSSELL. *Proc. Am. Gas Assoc.* 1925 (advance copy), 8 pp. — Continued tests of carborundum Bernitz blocks for water gas sets (cf. *C. A.* 19, 2405) show them to have considerable advantages as regards long life and decreased clinkering trouble; in one case a total saving of \$825 on one lining is estimated. Straight carborundum linings have lasted in 2 cases reported 6687 and 5548 hrs., but special precautions must be observed in laying the brick with close joints, penetration of air into seams causing swelling even to the point of shearing the rivets on the vertical seams of the shell.

WM. B. PLUMMER

Heating horizontal retort settings in small gas plants by coke breeze. C. A. WINKLER. *J. usines gaz* 49, 289–95 (1925). — A description of the Wilton hearth for burning fine fuels, and of its application in small horizontal retort plants, the economic advantages being considerable.

WM. B. PLUMMER

A notable advance in tar distillation. ALFRED OTT. *Apparatchau* 37, 243–4, 253–6, 274–5, 287–8 (1925). — Description, with 5 cuts, of the "Hermev semi-continuous, high-capacity process" in which the de-watering is continuous and the distn. is intermittent, with almost complete utilization of waste heat. Plans for a plant of 40 tons per day are given, the coal consumption being about 2000 kg. per day against about 5270 kg. for the usual methods.

J. H. MOORE

The recovery of brown coal tar in the production of cold producer gas in various plants in the Rhine district. HERMANN BECKER. *Braunkohle* 24, 633–6 (1925). — Yields of producer tar from brown coal briquets are 1.2–3.2%, from raw coal 1.0–1.7%. Operating and tar recovery costs are given for various types of plants. WM. B. P.

Determination of the apparent specific gravity of coke products. M. DOLCH. *Z. angew. Chem.* 38, 889–91 (1925). — A pycnometer and method of operation are described for the detn. of apparent sp. gr. of coke, etc., with sand, small shot, flax seed, etc., as filling materials. The accuracy of the method is approx. 2%. WM. B. P.

Pulverized coal as fuel for Cu-refining furnaces (BARDWELL, MILLER) 9. Evaporation of gasoline and benzene (FORMANEK, ZDARSKY) 22. Ca salts of the phenols from low temperature tar (GREENBAUM) 15.

Motor fuel. J. F. P. DE LARIBOISIERE. U. S. 1,557,257, Oct. 13. A mixt. of gasoline and C_6H_6 or a similar hydrocarbon fuel is mixed with aniline 1-3 and ether or acetone $1/2$ -3%.

Burning heavy hydrocarbon fuels. J. F. P. DE LARIBOISIERE. U. S. 1,558,967, Oct. 27. "Diesel oil," "fuel oil" or similar heavy hydrocarbon fuels are burned in the presence of a small proportion of dibenzyl diselenide or similar compd. of a hydrocarbon radical and a metal, in order to obtain increased efficiency, *e. g.*, in Diesel engines.

Burning liquid fuels. J. B. SWORD. U. S. 1,557,741, Oct. 20. The atomized fuel is mixed with a whirling stream of hot gaseous combustion products contg. O sufficient only partially to burn the fuel and then is burned substantially completely in a different portion of the combustion app. with additional O or air.

Fuel briquets. T. A. GOSKAR. U. S. 1,561,322, Nov. 10. See Brit. 231,934 (C. A. 19, 3583).

Fuel briquets. J. F. O'DONNELL. U. S. 1,557,320, Oct. 13. About equal amts. of fine anthracite and semibituminous coal dust are mixed with each other, molded under pressure and subjected to a temp. of about 510° for 3-6 min. (Cf. C. A. 19, 1343.)

Agglomerating coal particles. W. W. STENNING and W. H. BEASLEY. U. S. 1,560,116, Nov. 3. Finely divided coal is suspended in H_2O , mixed with a binding medium such as coal tar or pitch and subjected to heat and agitation without aeration, in order to effect agglomeration of the particles and prepare them for briquetting.

Carbonizing retort and gas generator for "total gasification" of coal or similar fuels. A. McD. DUCKHAM. U. S. 1,560,337, Nov. "

Apparatus for carbonizing and distilling coal, etc. N. H. FREEMAN. U. S. 1,558,974, Oct. 27.

Illuminating gas. L. S. STILES. U. S. 1,558,124-5, Oct. 20. App. is specified for making and carburetting water gas.

Combustion control. E. P. G. WÜNSCH. U. S. 1,550,410, Aug. 18. Waste gases from the combustion to be controlled are fed into contact with a wire (which may be formed of Pt or Pd or coated with these metals), and changes in elongation of the wire (induced by contact combustion of the waste gases catalyzed by it) are used to actuate regulating devices.

Portable testing apparatus for determining the gasoline content of natural gas. R. PONSLE. U. S. 1,556,712, Oct. 13.

Combustible gas. H. MEHNER. U. S. 1,550,558, Aug. 18. A bed of coal or other carbonaceous material is supported on a grate in the lower portion of a generator having an upper arch. Steam is admitted to a zone immediately above the carbonaceous material and combustible gas is admitted to a zone above the steam zone. Air is admitted to an upper combustion zone of the generator for heating the upper arch whence heat is radiated downwardly upon the carbonaceous material to produce gas which is drawn off from a zone below the grate.

Combustible gas. M. KLÖTZER. U. S. 1,559,622, Nov. 3. A mixt. of powdered fuel (such as semi-coke from coal distn.) and steam is introduced into a gas generating chamber over a heat-radiating bath of molten slag, the fuel mixt. is stirred by pulsation over the slag bath and gasification is effected by heat derived from the slag.

Gas producer. F. H. TREAT. U. S. 1,550,991, Aug. 25.

Retort for carbonizing wood, coal, shale, lignite or other solid fuels. A. L. J. QUENEAU. U. S. 1,560,855, Nov. 10.

Vertical apparatus for continuous distillation of lignite, peat, etc. J. PIETERS. U. S. 1,560,311, Nov. 3.

Coking-retort oven. J. BECKER. U. S. 1,556,749, Oct. 13.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Oil refining at Llandarcy. SIR J. CADMAN. *Petr. Times* 14, 17, 18, 71-4(1925) — Descriptive.

Study of nitrogen compounds in petroleum. J. R. BAILEY. *Refiner and Nat.* M. B. HART

Gasoline Mfr. 4, No. 9, 46, 48, 50, 53-4, 56(1925).—The work of previous investigators in this field is discussed, and the conclusion reached that California petroleum can probably be made to furnish a cheap source of quinoline bases which may be used as dye intermediates.

M. B. HART

Physico-chemical discussion of the source and storing of petroleum. M. A. RAKUZIN. *Petr. Z.* 21, 1258(1925).—The suggested formation of optically active petroleum is given in the following periods: formation period, racemization period, carbonization period and decompn. period.

M. B. HART

Evaporation of gasoline and benzene. J. FORMANEK AND J. ZDARSKY. *Petr. Z.* 21, 1197(1925).—The evapn. of gasoline and benzene was experimentally examd. In free evapn. of gasoline the air becomes more satd. with vapors than when air is bubbled through it; but in the latter case the air becomes quickly and uniformly satd. In the free evapn. expt. a certain time is required before the gasoline vapors diffuse uniformly in the air. The evapn. depends on temp., quantity of gasoline and size of container; and small pressure or vacuum exercises no great influence. Gasolines with sp. gr. less than 0.745, which contain over 30% boiling below 100°, give off combustible but not explosive gases, while gasolines with sp. gr. greater than 0.745 which contain less than 30% of a fraction boiling below 100° give off explosive or non-explosive vapors depending upon the temp. Benzene gives a non-explosive vapor air mixt. above 15°; below that temp. care has to be taken.

M. B. HART

Absorbers in natural gasoline plants. F. P. PETERSON. *Oil and Gas J.* 24, No. 16, 146(1925).—The combination of steel shavings with pans having perforated bottoms is the best filler for absorbers used in recovering gasoline from gas. The absorber should be anchored to the bottom. Time of contact between the gas and oil should be about one minute.

M. B. HART

Pressure in filtrating lubricants and washing filters. P. TRUESDELL. *Nat. Pet. News* 17, No. 31, 73(1925).—A description with diagram of the filtering process as conducted at the Tiona Refining Co.

M. B. HART

The measuring of viscosity by the Ostwald viscometer; conversion to time by the Redwood viscometer. S. T. MINCHIN. *J. Inst. Petr. Tech.* 11, 284(1925).—Ostwald viscometers were substituted for Redwood viscometers and conversion factors detd. By so doing, much time was saved and a smaller amt. of sample was needed. Results were as accurate as those in Redwood seconds and, further, the Ostwald tubes were more easily held at const. temp. in a thermostat.

M. B. HART

Determining the absorption and permeability of oil and gas sand. A. F. MELCHER. *Bull. Am. Assoc. Petroleum Geol.* 1925, 442; *Oil Weekly* 8B, No. 9, 37-8, 40(1925).—By means of specially designed app., which is described, oil and gas sand samples may be subjected to accurately measurable pressures, under which reliable quant. detn. of absorption and permeability of the sands for certain fluids such as oil, fresh and salt water, and gas can be made.

M. B. HART

An oil-bearing shale of North Carolina. FRANK C. VILBRANDT. *J. Elisha Mitchell Sci. Soc.* 41, 108-14(1925).—The distn. products of a shale from the Deep River coal field are given.

A. L. MEHRING

The prevention of explosions in air receivers. W. F. PARISH AND W. B. SMITH WHALEY. *J. Inst. Petr. Tech.* 11, 305(1925).—Air receiver and line explosions which are caused by explosive mixts. due to air and lubricating oil may be prevented by a receiver scavenger method. A scavenging valve allows air to enter and leave the receiver through the same opening and allows the pressure to open a passage for the compressed air to the top of the tank which process sweeps all vapors and gases from the receiver.

M. B. HART

Effect of heat upon the viscosities of lubricating oils. H. R. ARBUCKLE. *J. Elisha Mitchell Sci. Soc.* 41, 19-20(1925).—The oil showing the lowest viscosity at 70° F. had the highest at 150°, 200° and 225° of any tested. None of the oils tested, which were the grades available on the market, showed sufficient viscosity at 200° to be good lubricants.

A. L. MEHRING

Asphaltenes and resinous constituents of petroleum. A. SACHANEN. *Petr. Z.* 21, 1441(1925).—Natural and artificial asphalts are colloidal solns. of asphaltenes in resins and heavy oils.

M. B. HART

Valuable fuel from wood (ANON) 21. Apparatus for approximate or comparative melting points of fats, waxes and petroleum (STEVENS) 1. Fuel of high calorific value from wood (STRACHE) 21. Foam for extinguishing fires (U. S. pat. 1,558,599) 18.

Purifying oils. E. EICHWALD. U. S. 1,550,523, Aug. 18. In treating petroleum, tar oil from lignite or similar oils, for sepn. of aromatic from aliphatic and hydro-aromatic oil-like compds., furfurole is admixed with the oils, the mixt. is allowed to stand, and the layers which form are sepd. from each other.

Distilling oil. L. E. HIRT. U. S. 1,559,701, Nov. 3. A thin film of oil to be distd. flows through a series of tubes in which distn. takes place and a gaseous material such as steam is forced through the tubes mech. to remove vaporized constituents of the oil.

Petroleum oil conversion. C. P. DUBBS. U. S. 1,550,607, Aug. 18. A stream of oil such as gas oil, kerosene or pressure distillate bottoms is heated to conversion temp., while passing through a pipe coil under superatm. pressure and thence is passed into an enlarged reaction chamber from which vapors pass on to a dephlegmator. Charging oil passes in heat-interchange relation with the vapors and condensate in the dephlegmator and a second stream of oil is passed directly to the inlet of the heating coil. The preheated charging oil and condensate from the dephlegmator are passed to a pump which forces them into the second stream of oil to be passed to the heating coil. Cf. C. A. 19, 2742.

Cracking emulsified petroleum oil. G. EGLOFF and H. P. BENNER. U. S. 1,550,892, Aug. 25. Emulsified petroleum oil is subjected to surface heating alone to vaporize it at a cracking temp. and pressure.

Treating cracked oils. B. T. BROOKS. U. S. 1,550,673, Aug. 25. Lighter hydrocarbon oils obtained from the cracking of heavier oils are subjected, alone and in liquid form, to a high temp. (which may be about 275-360° below that at which any appreciable cracking occurs, under high pressure (which may amount to about 250 lbs. per sq. in.)) and the treatment is continued, preliminary to distn., until volatile coloring substances are converted into substances non-volatile during the subsequent distn.

Condensing hydrocarbon vapors. E. W. ISOM and J. E. BELL. U. S. 1,558,811, Oct. 27. Vapors such as those from petroleum cracking stills are passed into a stream of condensate which is maintained in circulation, by the action of the vapors, to and from a cooler.

Bleaching, desulfurizing and other treatment of petroleum oils. HERMAN REINBOLD and HUGO REINBOLD. U. S. 1,558,631, Oct. 27. LiCl is used with hydrous silicic acid for distg. oil to effect decolorization, desulfurization and formation of products of lower b. p. U. S. 1,558,632 specifies the use of LiCl and AlCl₃ together for the same purposes.

Dehydrating emulsified petroleum oils. G. EGLOFF and H. P. BENNER. U. S. 1,559,035, Oct. 27. The oil is passed through a series of spaced foraminous plates with foraminations of gradually decreasing size, under pressure, and simultaneously subjected to the action of elec. current as it passes through the plates.

Dehydrating petroleum oils. G. EGLOFF and J. C. MORRELL. U. S. 1,559,036, Oct. 27. A material such as NH₃, SO₂, Cl₂, H₂ or CO₂ is dissolved in the oil and H₂O to improve its conductivity and the material is then subjected to elec. and settling treatments.

Cracking hydrocarbon oils. R. T. POLLOCK. U. S. 1,550,568, Aug. 18. A restricted stream of oil, e. g., gas oil, is passed through a tube where it is heated to a cracking temp. and into an enlarged zone where conversion occurs. Vapors are passed to a dephlegmator through which charging stock is fed (in indirect heat-interchange relation) and condensate in the dephlegmator forms in pools through which the vapors pass. Reflux condensate and charging stock, though not permitted to mix in the dephlegmator, are afterward mixed and fed to the heating tube. The cracking operation is conducted under superatm. pressure.

Cracking or conversion of hydrocarbon oils. C. P. DUBBS. U. S. 1,551,090, Aug. 25. A stream of reflux condensate and charging oil is passed through a heating tube where the mixt. is heated to cracking temp. without, however, carrying the heating so high as to cause a substantial deposition of C in the tube. The heated mixt. is thence passed to an enlarged chamber where vapors and C sep. from the oil. The operation is carried out under pressure. Cf. C. A. 19, 2742.

Cracking fuel oil or gas oil. L. P. LITZINGER and P. F. CONERTY. U. S. 1,551,410, Aug. 25. Petroleum oils or residues of high b. p. undergoing cracking under pressure are subjected to a forced circulation of the oil toward a cool part of the still where the oil is agitated to prevent C deposition, a sepn. of the C particles being effected at the termination of a still run.

Avoiding "shock chill" in precipitating mineral "wax" from oil or other substances. L. D. JONES. U. S. 1,558,619, Oct. 27. In pptns. such as those of waxy substances from oils, the liquid from which the pptn. is taking place is cooled at a substantially

constant rate by heat absorption in a refrigerant; *e. g.*, brine, cooled at a rate bearing appropriate constant relation to changes in temp. of the liquid, so that a discontinuous ppt. is formed which is readily sepd. from oil by centrifuging.

Separating waxes from petroleum oils. F. PETTY U. S. 1,559,981, Nov. 3. A paraffin base crude mineral oil is refrigerated and subjected to centrifugal sepn. to sep. wax from the oil and the wax is subsequently distd. to drive off a cryst wax distillate, leaving as a residue wax which is mainly in amorphous form. U. S. 1,559,982 specifies subjecting a crude paraffin base oil to refrigeration and centrifugation to sep. wax, distg. the wax-free oil to obtain distillates of different b. p., dilg. the residue with a petroleum oil of low b. p., subjecting the blended materials to successive treatments with acid and alkali and then to distn.

Gasoline recovery by absorption. H. B. BERNARD U. S. 1,560,137, Nov. 3. A liquid absorbing medium with associated gasoline which may have been absorbed from natural or casinghead gas is subjected to distn. and the heated liquid residuum from the distn. is passed in countercurrent flow and in "indirect contact" with the distd. vapors and gases under a pressure lower than that prevailing in the distn. treatment. U. S. 1,560,138 specifies absorption of gasoline from natural gas, casinghead gas or the like, in a liquid absorbing medium followed by a preliminary heating and distn. and passing of the liquid from the distn. treatment while hot in countercurrent flow and in "indirect contact" with the distd. gases and vapors. Both pats. describe app.

Still for cracking petroleum oils. W. I. BAGWILL U. S. 1,560,891, Nov. 10. A still body is formed with a substantially ovate cross section with flat sides and the apex at the bottom, provided with continuous combustion passages which extend through the body lengthwise from end to end. The uppermost passage is of the largest diam. and the other passages are of progressively diminishing diam. and the passages are so mounted in the still that the oil between the passage and the lateral walls of the still is substantially the same thickness for each passage.

Still for petroleum oils. W. M. FRASER U. S. 1,561,428, Nov. 10. A fluid motor inside a still and actuated by oil as fed into the still serves to operate a chain mechanism or other agitating device within the still which loosens C deposits from the inner surface of the still.

Apparatus for distillation of mineral oils. H. G. W. KITTREDGE U. S. 1,561,169, Nov. 10.

Apparatus for separating oil from water at oil wells. W. B. SMITH U. S. 1,557,103, Oct. 13.

Tank for separating gas and water from oil. F. A. RAY U. S. 1,551,329, Aug. 25.

Apparatus for forming bituminous emulsions. I. KIRSCHBAUM U. S. 1,560,826, Nov. 10.

Superposed horizontal cylindrical retorts for distillation of oil shale or similar materials. W. H. ALCORN U. S. 1,556,894, Oct. 13.

Lubricant. M. F. WEBSTER U. S. 1,559,592, Nov. 3. A lubricant for use on tank car valve parts, etc., which may be subjected to the action of gasoline and H_2O , comprises castor oil 80 and carnauba wax 20%.

Lubricant. A. G. MARSHALL U. S. 1,561,261, Nov. 10. In prepg. a lubricant adapted for use in internal combustion engines, castor oil and mineral oil are heated together until soln. is effected, the soln. is allowed to cool until a sepn. into layers is completed, and the lower layer is then drawn off and admixed with such a further quantity of castor oil as will prevent any further sepn. at 0°.

Solid lubricant. F. T. MANLEY U. S. 1,550,912, Aug. 15. A lubricant adapted for use in heavy journal bearings, etc., comprises soap 60, a paraffin base cylinder stock 15, H_2O 10, an asphaltic base residue 15 parts and a small quantity of graphite.

Lubricating oil. W. F. FARAGHER, R. W. HENRY and W. A. GRUSE U. S. 1,550,608, Aug. 18. A basic Al oleate in which the ratio of Al to oleic acid is about 1 to 1 is used for thickening mineral oils.

Treating lubricating oils from crank cases, etc. V. S. ALLEN U. S. 1,550,396, Oct. 6. Crank case oil or similar used lubricating oil, after setting while warm, is centrifuged, steamed to free it from volatile oils, again centrifuged and treated with fuller's earth. Decolorizing C is added to the oil prior to one of the centrifugings.

Destructive distillation of wood. D. P. SHAW U. S. 1,559,994, Nov. 3. A mass of wood is progressively burned from one end of a kiln to the other, in a substantially horizontal direction, and the distd. vapors are withdrawn from a zone in advance of the progressively burning portion in a manner substantially to avoid intermixing of the vapors with any combustion gases which contain no tar vapors.

Apparatus for wood distillation. J. L. WEAVER U. S. 1,560,517, Nov. 3.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The depolymerization of cellulose. E. HEUSER. *Z. Elektrochem.* **31**, 498-502 (1925).—The first step in depolymerization is the methylation of the variously pre-treated cellulose preps. to obtain water-sol. products. Treatment of this water-sol. material in different ways, as by HCl, yields products whose decreased mol. wt. indicates that changes have been brought about by depolymerization. The mol. wt. of copper ammonium cellulose lies between 3000 and 3500. Visco-cellulose gives a high degree of depolymerization. Curves show the change in important properties of cellulose with decrease in mol. wt. Discussion follows.

ROSALIE COBB

Determination of pentosans in wood. WALTER GIERISCH. *Cellulosechemie* **6**, 61-74, 81-93 (1925).—By correlating the results of a no. of equal color reactions that were applied to the distillates obtained by heating various carbohydrates, beech wood, spruce wood, and hydroxymethylfurfural *I* with 12% HCl (as in Tollens' pentosan method), G. concludes that the first few cc. of the HCl wood distillate contain appreciable amts. of *I*. The color reactions of *I* are disguised as the distn. proceeds by the intensive colorations given by furfural *II*. *I* in HCl gives a red color with resorcinol, a green color with orcinol red, followed by violet with peptone, a yellow color with very slight reddish tone with α -C₁₀H₇NH₂ and a yellow color with barbituric acid. Very similar colors are given by the same reagents with the HCl distillates of beech and spruce, and with the first 35 cc. of distillates obtained from various hexoses. On the other hand, *II* obtained from xylose, and methylfurfural *III* obtained from rhamnose gave very different colors, especially with peptone and resorcinol. The color reactions did not serve to differentiate between different hexosans occurring in the wood. G. also critically studied various pentosan methods. In the case of wood, the phloroglucinol method serves only to det. the sum total of *I*, *II* and *III* in the Tollens distillate. The attempted use of EtOH as a solvent for the phloroglucide of *III* with a view towards detg. *II* fails utterly, since the phloroglucide of *I* is partially sol. in EtOH, and gives high values for both *II* and *III*, when applied to the analysis of woods. In fact the presence of *III* in the HCl wood distillates was not indicated by the usual color reactions, but these negative results do not necessarily prove its absence. If present, however, *III* occurs in relatively small amts. The semioxamizide method cannot be applied directly to the Tollens distillate, because of its high acidity. Modifications of the method serve no useful purpose, since it ppts. *I* and requires the detn. of a set of factors to permit the calen. of *II*. Barbituric acid served as the best reagent in the pentosan detn. It ppts. *II* and *III* with the min. pptn. of *I*. Pure *I* is pptd. by barbituric acid only when concns. are quite high. When *I* is subjected to the Tollens distn. an appreciable amt. is converted into *II*. On the other hand, carbohydrates giving rise to *I*, when heated with HCl, yield very small amts. of *II*, since *I* is distd. off as rapidly as it is formed. The barbituric acid method when applied to woods gives the best values for *II*, and is recommended for the pentosan detn. The yields of *II* vary with the size of the sample taken for analysis, and for comparative results the amt. of sample should not be varied. When the phloroglucide of *II* is extd. with alc., AmOH and AcOAm, adsorption of the solvent takes place, and causes an actual gain in wt. even after protracted drying. The phloroglucide of *II* is very insol. in AmOH. Fractional HCl distn. of red beech wood using both the phloroglucinol and the barbituric acid methods gives the following insight into the hydrolysis of pentosans and hexosans in the wood: in the first 60 cc. of the HCl distillate *I* is found in gradually decreasing amts., which reach a min. between 60 and 90 cc. From this point on until the end of the distn. (420 cc.) an increase of *I* occurs. The production of *II* rises from the beginning of the distn., reaches its max. between 30 and 60 cc. and is complete when 150 cc. have been distd. *III* if it occurs at all is not produced after the first 150 cc. G.'s interpretation of these data is that the hemicellulose hexosans are rapidly hydrolyzed and converted into *I* at the outset of the distn., and that the later production of *I* is due to the degradation of cellulose. The technic of the Tollens method is simplified by adding 200 cc. of boiling HCl directly to the 2 g. wood sample, and maintaining the reaction mixt. at 140° by use of a CaCl₂ bath. The distn. is complete in about 1.25 hrs. and the addn. of 30 cc. portions of HCl is obviated. G. gives complete tabulated data as well as graphs. LOUIS E. WISE

Metallurgy of Fe drier rolls (BOLTON) 9.

Chlorination of cellulosic materials. A. R. DE VAINS. U. S. 1,556,497, Oct. 6.

In neutralizing the acids set free by the chlorination of ligno- and pecto-cellulose or similar cellulosic materials and dissolving out the chlorinated derivs., an alk. earth metal compd. such as $\text{Ca}(\text{OH})_2$ or CaCO_3 is used for the neutralization and an alk. compd., *e. g.*, NaOH , NH_4OH or Na_2CO_3 , for dissolving the chlorinated derivs. U. S. 1,556,498 specifies continuous chlorination of cellulosic materials by continuously introducing a chlorinating agent, *e. g.*, a Cl soln., and the materials into a chlorination vessel, controlling the supply of chlorinating agent by the pressure in the chlorination vessel and regulating the supply of cellulosic material in accord with the discharge of chlorinated product. Cf. C. A. 13, 1347.

Halfstuffs and cellulose from vegetable fibers. R. RUNKEL. U. S. 1,557,338, Oct. 13. Vegetable fibrous materials of various kinds, including peat or wood chipings, are treated with Cl and alkalis such as soda soln. simultaneously, and, with repeated addn. of alkali, the obtainment of a pure white cellulosic material is possible.

Cellulose acetate. E. S. FARROW, JR. U. S. 1,557,147, Oct. 13. CHCl_3 sol., cellulose acetate is dissolved in a soln. of H_3PO_4 "of a type which is liquid above its m. p.," *e. g.*, H_3PO_4 of 70–85% strength, and while so dissolved is partially hydrolyzed to render it sol. in acetone. Cf. C. A. 19, 729.

Cellulose acetate. E. S. FARROW, JR. U. S. 1,560,554, Nov. 10. For sepg. and subdividing cellulose acetate from a reaction mixt. of high viscosity, blades are forced through the mixt. and H_2O in liquid form is gradually added until cellulose acetate is pptd. in subdivided form.

Cellulose acetate. A. F. SULZER. U. S. 1,560,620, Nov. 10. A cellulose acetate reaction mixt. contg. volatile acetic values is heated to a temp. (suitably about 40–80° *in vacuo*) to volatilize the acetic values without degrading the cellulose acetate, and the vapors evolved are removed and liquefied.

Cellulose acetate composition. S. J. CARROLL. U. S. 1,560,542, Nov. 10. A compn. adapted for making sheets or films comprises a soln. of colloiddized acetone-sol. cellulose acetate contg. cresyl *p*-toluenesulfonate.

Paper pulp. B. T. MCBAIN, J. H. ALEXANDER and G. GENBERG. U. S. 1,560,591, Nov. 10. In making light colored paper from resinous wood, the wood is treated by the usual sulfate process and the resulting pulp is then cooked with acid sulfite soln.

Sizing paper. J. A. DECEW. U. S. 1,558,845, Oct. 27. Pptn. of rosin from size is effected after completion of the beating action of the Jordan engine. U. S. 1,558,846 specifies treating paper pulp with rosin emulsions and colloidal $\text{Al}(\text{OH})_3$, and, after the rosin emulsions are coagulated, adding $\text{Al}_2(\text{SO}_4)_3$.

Sizing paper "in the pulp." J. PELZER. U. S. 1,550,632, Aug. 18. In sizing with rosin size, the concn. and alkalization during sizing are controlled to produce as large an amt. as possible of a compd. of the formula $\text{C}_{20}\text{H}_{30}\text{O}_2\text{Na} \cdot 3\text{C}_{20}\text{H}_{30}\text{O}_2$ in the soln.

Apparatus for hydrating, beating and refining stock for paper making. E. B. FRITZ. U. S. 1,556,926–7, Oct. 13.

Device for testing the rate of absorption of liquids by fibrous sheet materials. F. A. SESLER. U. S. 1,561,285, Nov. 10. The app. is especially adapted for testing the absorption of binders by paper or textile fabrics.

Chemical wood pulp. G. A. RICHTER. U. S. 1,557,880, Oct. 20. Chips are exposed to the action of combustion gases which have been suitably cooled partially to dry the chips. The gases are in part recirculated. An app. is described. Cf. C. A. 19, 2878.

Pulp and by-products from resinous wood. J. H. WALLACE. U. S. 1,560,446, Nov. 3. Resinous wood such as pine is subjected to extn. with a distillate from resinous wood, b. 170–185°, or a similar solvent as long as extn. of resinous substances readily is accomplished. The ext. is then sepd. and the wood disintegrated with a heated alk. soln. such as NaOH to produce pulp. Residual non-volatile and solid resinous substances are recovered from the spent alk. soln. U. S. 1,560,447–8 also relate to similar processes.

"Quick-Cook" sulfite pulp manufacture. P. C. ULMEN, H. H. BECKER and R. T. MANN. U. S. 1,560,881, Nov. 10. In discharging "quick-cook" sulfite digesters, the spent liquor is strained off and cold H_2O is simultaneously injected quickly to reduce the temp. and pressure within the digester. The cooked chips are then washed out.

Recovering values from waste sulfite liquor. V. DREWSON. U. S. 1,560,900, Nov. 10. The waste liquor is concd. until it contains only about 50% H_2O and mixed with niter cake and with 10–30% of hydrated lime to fix the organically combined S and minimize its elimination. The mixt. is then incinerated and melted to produce Na_2CO_3 and Ca sulfide, Na salts are leached out, and the residue is treated to form

SO₂ which is combined with the Na salts to form Na monosulfite for prepg. pulp cooking liquor

Recovering sodium acid sulfite from waste sulfite liquor. J. BEVERIDGE. U. S. 1,560,649, Nov. 10. A portion of waste sulfite liquor, after draining from the pulp, is neutralized, e. g., with NaOH or Na₂CO₃, evapd, mixed with unneutralized liquor, carbonized, and the carbonized product is leached with H₂O to form a soln. contg. Na sulfite, etc.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

The dangers in autogenous work. GEORG EPSTEIN *Apparatebau* 37, 248-9, 263-4, 278-9, 291(1925) —Discussion of the sources of explosions of C₂H₂, H and of cylinders, with a few precautions.

Aerosols in industry. W. F. GIBBS *Colliery Guardian* 130, 972(1925) —A description of the principles involved in the formation of aerosols, their properties and the factors involved in dust explosions in industry.

Explosion of gunpowder press house at factory, No. 38, Kent. R. A. THOMAS Special Rept H. M. Inspectors of Explosives, No. CCN111 July, 1925 Mimeographed, 8 pp. —The explosion occurred May 16, 1925, at the time when mill powder from the "charge" house and powder dust from the corning-house (which was being brought to the press house by a boat on the canal running alongside of the press house) was about to be discharged from the boat. It was learned that the bow of the boat was shod with galvanized iron and that the boatman was behind his schedule. The evidence clearly showed that the powder aboard the boat exploded before that in the press house. It was concluded that the boatman, in his hurry, passed beyond his landing place; that the bow of his boat struck the concrete wall at the end of the canal; and that the friction ignited powder dust which fired the powder charges on the boat and eventually caused the charges in the press house to explode. CHARLES E. MUNROE

Prevention of explosions in air receivers (PARISH, WHALEY 22.

Explosive. E. M. WERNER U. S. 1,550,639, Aug. 18 KClO₃ for use in explosives is associated with a substance such as glycerol and a vegetable oil which will reduce the sensitiveness of the powdered chlorate to friction without inhibiting its usefulness in explosive mixts when ignited by detonators.

Explosive. H. A. LEWIS. U. S. 1,560,426, Nov. 3 A condensation product is formed from ethylene glycol or other polyhydric alcohol contg. not more than 3 OH groups and 4-dinitrochlorobenzene or other nitrochloro aromatic compd. and this condensation product is then nitrated with HNO₃ and H₂SO₄ to form an explosive for detonators, "booster" charges, etc.

Explosive. R. C. MORAN. U. S. 1,560,427, Nov. 3 A condensation product is formed from aminocethyl alc or other amino aliphatic alc and 2,4-dinitrochlorobenzene or other nitrochloro aromatic compd. and this condensation product is then nitrated.

Propellent explosives. G. C. HALE and F. OLSEN U. S. 1,550,960, Aug. 25. In incorporating nitroguanidine and nitrocellulose, the nitroguanidine is treated with a solvent such as *p*-tolylmethylketone, benzaldehyde, diacetin or urethan which also acts as a colloidng agent for the nitrocellulose Cf C. A. 19, 3021

Coating grains of nitrocellulose explosives. T. L. DAVIS U. S. 1,561,219, Nov. 10. Sym-dimethyl-(or diethyl-) urea or other urea symmetrically substituted by only 2 alkyl groups is used for coating or colloidng.

Fuse for explosives. W. O. SNELLING. U. S. 1,561,366, Nov. 10 A powder core of a fuse is covered with a waterproofing coating formed from a material (such as China wood oil, a synthetic resin or rubber mixed with S and (CH₂)₆N₄) which tends to vulcanize with increasing temp. This coating serves to avoid preignition by the fuse.

Projectiles filled with guanidine picrate. F. OLSEN U. S. 1,558,565, Oct. 27 The guanidine picrate is compressed to a d. of not less than 1.50. Paraffin, TNT, etc., may also be added.

Dynamite cartridges. M. BRANDT. U. S. 1,550,670, Aug. 25. Dynamite is enclosed directly in rubber-treated paper of such character as to be consumed when the cartridge is exploded.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

A list of the principal group names of commercial dyes and pigments with their classification as regards application and the manufacturer's address. CHAS. E. MULLIN. *Textile Colorist* 47, 706-7 (1925).—A directory of dyestuff manufacturers and dealers.

CHAS. E. MULLIN

The relation between constitution and dyeing properties. HANNS JOHN. *Z. angew. Chem.* 38, 903-4 (1925).—2-Phenyl-4-methyl-6-hydroxyquinoline (I) has been coupled with 12 diazo compds. and the resultant colors have been compared with those produced by using the same diazo compds with β -C₁₀H₇OH (II) or naphthol AS (III). The colors from I had more fastness to alk.-soap than those of II or III, but the same or less to light. The tone was less lively than with II or III; the shades were much more yellow than those of III and in most cases than those of II also.

WM. B. PLUMMER

Dyeing of acetate silk. C. E. MULLIN. *Am. Dyestuff Rept* 14, 182-4, 510-1, 517-21, 554-6, 577-8, 588-93, 622-7, 653-8, 694-9 (1925); cf. *C. A.* 19, 2748.—This series of papers closes with a list of precautions in part as follows: Always wet process acetate silk at temps. below 85° and preferably below 80°. Avoid the use of strong alkalies especially on Celanese. Use only neutral soap solns whenever possible. Use no mineral acids on acetate silk if it can be avoided. Use AcOH and HCO₂H. On Lustron whatever the dyeing process the last rinse water should contain about 15 g. of NaHCO₃ per gal. The goods should be dried from this rinse so as to finish slightly alk. Acetate silk should not be run over bare Cu drying cans or other hot metal; it should be dried below 85°. In finishing goods must not be stretched beyond the gray width. In laundering the goods should be handled in the same manner as real silk rather than cotton.

L. W. RIGGS

The dyeing of cellulose acetate silk and of mixed fabrics containing cellulose acetate. E. DUNEM. *Tiba* 3, 1067-77 (1925).—An address briefly reviewing the various processes.

A. PAPINEAU-COUTURE

The formation of colors (in vat dyeing). KURT BRASS. *Z. angew. Chem.* 38, 853-7 (1925).—Expts. have been carried out on the affinity of the cellulose fiber for the free leuco acid and for the Na salt thereof of various vat dyes, viz., indanthrene blue RS, yellow R, orange gold G and orange RRT. By using a closed flask with suitable inlets the cotton was treated for 1 hr. at 60° with the usual dye bath (Na salt of the leuco compd.) in an atm. of CO₂, N₂ or O₂, then boiled up with soap soln., the same atm. being maintained and finally oxidized in air. With CO the final color was deeper than the control run in air, while if N₂ were used the soap soln. extd. the leuco salt from the fiber, the final oxidation giving merely a discolored product. Evidently the dyeing process requires the pptn. of the free leuco acid and the fiber by the CO₂ of the air. On carrying out the process in O₂ the final color was apparently developed during the first step of the above expts., but on boiling with soap soln. it was almost completely extd., showing that the free leuco acid must be adsorbed by the fiber before oxidation.

WM. B. PLUMMER

Testing the fastness of dyed colors to light. H. B. GORDON. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 158-62, 167-73, *Am. Dyestuff Rept* 14, 488-92, 497-503.—In order to be suitable for testing the fastness of colors the light used should (1) give essentially the same results with all dyes as does sunlight, (2) act more rapidly than sunlight on all colors, (3) operate without much attention and (5) be accurately reproducible in order that similar results may be obtained in different labs. Among the lights studied, the violet carbon arc best meets the foregoing conditions. L. W. R.

Some uses of lactic acid in the textile industry. N. BOURGUIGNON. *Tiba* 3, 1011-9 (1925).—Brief review of the properties of lactic acid, its utilization for producing silk effects, and its technical control.

A. PAPINEAU-COUTURE

Weights and measures of the finishing department. H. D. MARTIN. *Textile Colorist* 47, 699-700 (1925).—The importance of checking the wt. and measurements of cloth as received for finishing as well as after this operation.

CHAS. E. MULLIN

Finishing of linen. F. BRADBURY AND W. HAGGAN. *Textile Recorder* 42, No. 505, 67-9, No. 506, 63-5 (1925); cf. *C. A.* 19, 1951.—A description of the app. and methods of moistening, starching, drying, stentering, calendaring, glazing, chasing and mangling.

CHAS. E. MULLIN

Woolen and worsted cloth finishing. TINDAIRS. *Textile Recorder* 43, No. 507,

63-5; No. 508, 59-61; No. 509, 61-3, 69(1925).—A description of the app. and methods.

CHAS. E. MULLIN

Processing of cotton. S. V. DEFOREST. *Chemicals* 24, No. 15. 31-2(1925).—A discussion of cotton impurities and their removal.

CHAS. E. MULLIN

Deleterious substances in wool. F. B. HINTON. *Agr. Gaz. N. S. Wales* 36, 495-6(1925).—Admixed jute fibers from coverings used on the bales of wool, and certain compds. such as CuSO_4 and coal tar, frequently present in sheep-branding specifics and blow-fly remedies, produce imperfections and discolorations in the dyed product. Expts. to det. the best methods for eliminating these undesirable features are being carried out.

K. D. JACOB

Classification of raw silk by means of mechanical tests. K. R. MOORE. *Am. Dyestuff Rept.* 14, 551-2, 579-83, 619-21, 689-90(1925).—The phys. and structural properties which are examd. in classifying silk in accordance with mech. measurement are as follows: color, luster, handle (resiliency), nature (soft, medium, hard), cohesion, strength, ductility, evenness and cleanness. The defects are classed as: slugs, bad throws, waste, split ends, bad knots, hairiness, nibs, corkscrews and loops. The procedures for carrying out the phys. tests, instruments employed and the method of recording results are described.

L. W. RIGGS

The manufacture of balloon fabrics. DAMBROISE. *Rev. gén. caoutchouc* 1925, No. 15, 16-8.—A general description, including the rubberizing process, curing with S_2Cl_2 , testing and the use of protective pigments.

C. C. DAVIS

Study of N compounds in petroleum [source of quinoline bases] (BAILEY) 22. Device for testing the rate of absorption of liquids by fibrous sheet material (U. S. pat. 1,561,285) 23. Dyeing rubber (U. S. pat. 1,559,343) 30

Dyes. W. HERZBERG and G. HOPPE. U. S. 1,556,326, Oct. 6. 2-Hydroxy-3-(2'-nitrophenylmercapto)-1,4-naphthoquinone is dissolved in NaOH soln. and decolorized with Na hyposulfite and then treated with air until it assumes a dark brown color, and acidified. The liquid thus formed solidifies, more readily when warmed, to a thick violet dye magma. The dye may be obtained as a cryst. powder. A similar thiazine dye is obtained from 2-hydroxy-3-(2'-nitro-4'-chlorophenylmercapto)-1,4-naphthoquinone (a brownish yellow powder m. 210° and obtained from 2-nitro-4-chloro-1-thiophenol). Other examples also are given of the formation of similar dyes from analogous starting materials. The dyes produce on wool green chrome lakes of good fastness to light.

Dyes. J. G. DINWIDDIE. U. S. 1,558,252, Oct. 20. A dibrominated (or other halogenated) isatinchloride is condensed with 2-hydroxy-3-methyl-5-chlorothionaphthene, forming dyes which give fast violet shades on cotton.

Dyes of the anthraquinone series. A. H. DAVIES, R. F. THOMSON and J. THOMAS. U. S. 1,531,260, March 24, 1925. Isodibenzanthrone is oxidized, e. g., by the action of H_2SO_4 and MnO_2 , and the product is alkylated or otherwise treated to produce dyes which in general produce fast blue dyeings of various shades. The oxidized isodibenzanthrone may be subjected to a partial reduction before alkylation.

Dyes from dibenzanthrone, etc. A. H. DAVIES and R. F. THOMSON. U. S. 1,531,261, March 24, 1925. Alkyl derivs. of dibenzanthrone and similar compds. form dyes of various shades among which are green, violet, blue and brown which give fast dyeing on cotton. Numerous examples are given. U. S. 1,531,262 specifies treatment of the oxidation product of dibenzanthrone with Me_2SO_4 . A blue-green dye is produced. U. S. 1,531,263 specifies oxidation and subsequent reduction of substituted dibenzanthrones such as dichlorobenzanthrone to form dyes which give green or blue shades on cotton.

Green-blue dyes of the triphenylmethane series. R. GESING and R. REYHER. U. S. 1,550,534, Aug. 18. Dyes fast to alkali are obtained by condensing 1 mol. proportion of *o*-sulfobenzaldehyde with 2 mol. proportions of alkylbenzylarylamines which are substituted in the benzyl residue by halogens and sulfonic groups, and oxidizing the condensation products.

Azo dyes. J. HALLER. U. S. 1,529,739, March 17, 1925. Diaminodisazo dyes are prepd. by combining tetrazotized aromatic diamines free from sulfonic groups with amines which can be further diazotized. The tetrazo compds. of these diamino-diazo dyes yield, when combined with arylides of 2,3-hydroxynaphthoic acid, insol coloring substances which in general are black or blue-black. The middle components should be free from sulfonic groups. Suitable amines are: *m*-aminoacetanilide, acetyl-

toluylenediamine, *m*-toluidine, lidine, ~~pyridine~~ *N*-phenylamine and its derivs. with a free 4 position.

Azo dyes. H. FRITZSCHE. U. S. 1,539,353, May 26, 1925. Polyazo dyes are obtained by reacting on 2 mol. proportions of 1-aminoaryl-3-pyrazolones (*e. g.*, 1, 3'-aminophenyl-5-pyrazolone-3-carboxylic acid) in any desired sequence, with 1 mol. proportion of phosgene and 2 mol. proportions of diazotized azo dyes, *e. g.*, the diazo deriv. of 4-amino-3-tolueneazo-2'-toluene-4'-sulfonic acid (which gives a dye producing orange tints on cotton).

Chromium compounds of azo dyes. H. FRITZSCHE, E. REBER and F. STRAYB. U. S. 1,529,995, March 17, 1925. Complex compds. of azo dyes with Cr are obtained by the action of chroming agents as Cr_2O_3 , $\text{Cr}(\text{OH})_3$ or their compds. with alkalis or weak acids, upon *o*-hydroxyazo dyes which are obtained by coupling 1-aryl-5-pyrazolones carrying an SO_2NH_2 group in their aryl nucleus with *o*-hydroxydiazocompds. They form dark powders sol. in alk. aq. solns. and dye wool in an acid bath orange to blue-red tints fast to fulling and to light. Several examples are given.

Disazo dyes. R. C. MILLER. U. S. 1,557,265, Oct. 13. Diazo compds. of *p*-aminoazoxylenes are combined with β -hydroxynaphthoic acids. The products are insol. in H_2O , fast to light and dye red to blue shades. They may be used with oils, waxes, rubber, lacquers and other non-aq. substances.

Disazo dyes containing a diphenylurea nucleus. L. W. GELLER. U. S. 1,538,934, May 26, 1925. Azo dyes for use on unmordanted cotton and also adapted for use on wool, silk and other fibers (giving yellow dyeings) are obtained by converting into a urea compd. the aminoazo dyes produced by combining diazotized 3-amino-4-methylbenzene-1-sulfonic acid with an equimol. proportion of a 4-alkoxy- (*e. g.*, 4-methoxy- or 4-ethoxy)-3-amino-1-methylbenzene.

Vat dyes of the anthraquinone series. P. NAWIASKY and K. SAURWEIN. U. S. 1,539,689, May 26, 1925. Anthraquinonecarboxylic acid amides in which a H atom of the amide group attached to a carboxyl is substituted by an anthraquinone residue (corresponding to the general formula A-CO-NH-A' , in which A and A' are anthraquinone residues) may be used as vat dyes provided one or both of the anthraquinone residues contain at least 1 amino group which may be either a primary amino group or substituted by any radical other than an anthraquinonecarboxylic acid residue. Other substituents may also be present in one or both of the anthraquinone residues. The dyes generally produce red shades but some give orange or violet. Several examples are given.

Dyeing sulfur colors on silk. F. L. REMLEIN. U. S. 1,551,330, Aug. 25. The alkalinity of the dye bath is reduced with Na hyposulfite and NaHSO_3 , gum soap also being added to the amt. of 0.75-5%.

Artificial silk. O. LEUCHS and E. HÜBERT. U. S. 1,558,375, Oct. 20. Before spinning filaments, the portions of the app. used which come into contact with the pptg. liquid are freed from accumulated air in order to avoid breaks in the filaments produced.

Artificial silk. H. P. BASSETT and T. F. BANIGAN. U. S. 1,560,965, Nov. 10. A soln. of acetyl nitrocellulose in acetone is passed from a spinneret through a shallow body of acetone and H_2O and then delivered through a body of air.

Artificial silk from cellulose acetate. H. S. MORK and C. F. COFFIN, JR. U. S. 1,551,112, Aug. 25. A soln. of cellulose acetate in $\text{C}_2\text{H}_5\text{Cl}_4$, alc. and kerosene or other aliphatic hydrocarbon material is coagulated in a bath which also contains an aliphatic hydrocarbon material such as kerosene 90 together with $\text{C}_2\text{H}_5\text{Cl}_4$ 10%.

Artificial silk from viscose. I. O. E. LAMS. U. S. 1,558,265, Oct. 20. Viscose threads are subjected to the action of an aq. soln. contg. NH_4 formate 13-15 and Na formate 13-18%, the threads are drawn while so coagulated, and are then converted into cellulose hydrate.

Apparatus for manufacture of artificial silk filaments. H. KEMPF. U. S. 1,558,371, Oct. 20.

Gutter or channel for treating imitation-silk yarns, etc., with acid liquids. E. ELSAESSER and W. ZUR LÖWEN. U. S. 1,561,445, Nov. 10.

Acid-circulating system for mercerizing yarn. L. A. STEAD. U. S. 1,558,060, Oct. 20.

Apparatus for bleaching, dyeing and other treatments of textile fabrics. JOHN BRANDWOOD, THOMAS BRANDWOOD and JOSEPH BRANDWOOD. U. S. 1,558,460, Oct. 27.

Viscose. J. HUBER and P. ECKERT. U. S. 1,550,360, Aug. 18. Na silicate or other inorg. colloid capable of modifying the physical properties of the formed viscose is added to the lye in which the xanthate is to be dissolved in the manuf. of formed viscose. U. S. 1,550,361 specifies the similar addition to the lye of an emulsoid such

as agar-agar in prepg. viscose for the manuf. of artificial silk of especially soft texture, high degree of toughness, tensile strength and extensibility.

Treating cellulose fibers with sulfuric acid and formaldehyde. F. L. BARRETT and R. P. FOULDS. U. S. 1,558,453, Oct. 27. See Can. 248,412 (C. A. 19, 3163).

Bleaching piece goods. J. C. McDOWELL. U. S. 1,558,104, Oct. 20. In bleaching piece goods contg. yarns dyed with vat colors, the material is boiled under pressure for 6-10 hrs. in an aq. soln. contg. Na silicate and Na_2CO_3 which serve to prevent undesirable changes in the dyed portions.

Bleaching washed goods. M. G. DONK and W. D. MARSHALL. U. S. 1,550,518, Aug. 18. The goods are agitated in a soln. of Na_2CO_3 or other alk. soln. and Cl⁻ is introduced. The alkalinity of the soln. is maintained at such a point that no substantial amt. of HOCl will be formed.

Preparing fibers for spinning. L. UBBELOHDE. U. S. 1,550,598, Aug. 18. The spinning qualities of wood pulp, "cottonized" flax or similar fibers is improved by agitating the fibers with sharp-edged chip like material such as glass powder, carborundum or infusorial earth.

Oiling cotton raw stock. R. B. SMITH. U. S. 1,550,396, Aug. 18. Lubricating oil in liquid form is applied to the stock prior to the completion of the drawing operation and the oil is permitted to penetrate the stock during the drawing operation.

26--PAINTS, VARNISHES AND RESINS

A. H. SABIN

The effect of adding zinc oxide to iron oxide paints. H. A. NELSON. *Drugs, Oils and Paints* 41, 101, 51-4 (1925).—The results of a large no. of exposure tests of iron oxide linseed oil paints on iron panels are presented, with photographs. These show that the addn. of 15 to 20% ZnO to the pigment portion of the paints increases the useful life of the paint films to approx. double that of the paint contg. no ZnO. It is necessary that the ZnO be present in the film next to the metal. A large variety of Fe_2O_3 pigments was used, in general it appears that the oxides of very high Fe_2O_3 content such as Indian red, and the Venetian reds are not suited for use in metal priming paints.

F. A. WERTZ

Uniform procedure for the simple testing of paints and varnishes. ANON. *Farben-Ztg.* 30, 3052 3(1925); *Farbe u. Lacke* 1925, 443-5.—Uniform elementary comparative methods for testing brushing quality, spreading rate, drying time, color permanency, etc., of paints, as adopted by the producers, dealers and consumers, are given. Cf. C. A. 19, 900.

F. A. WERTZ

The drainage of fire hazardous liquids in the varnish and paint industries. S. ROEDER. *Farbe u. Lacke* 1925, 493.—A review of the fire hazards resulting from running of waste liquids contg. volatile combustible matter into drainage sewers, with suggestions for minimizing the danger by use of separator basins, etc.

F. A. W.

Cobalt colors. R. K. GOSSELTZ. *Farbe u. Lacke* 1925, 491-2.—A review of the history of the use of Co colors, of their manuf. and uses.

F. A. WERTZ

The permanency of pigment colors to light. KAISER. *Farben-Ztg.* 30, 3121 3 (1925).—Review.

F. A. WERTZ

Commercial practice in the washing of earth colors. ANON. *Farbe u. Lacke* 1925, 445.

F. A. WERTZ

Newer ideas for waterproof coatings. ALBERT REICHERT. *Farbe u. Lacke* 1925, 458-9.—A review of patents covering the use of metallic soap solns., etc., for waterproofing.

F. A. WERTZ

Kaolin. ANON. *Farbe u. Lacke* 1925, 460.—A brief review of the source, compn. and uses of kaolin in the manuf. of lakes, ultramarine pigments, etc.

F. A. WERTZ

The production of zinc white. ANON. *Farbe u. Lacke* 1925, 468-9.—A very brief review.

F. A. WERTZ

Mars yellows. ANON. *Farbe u. Lacke* 1925, 469.—A review of the methods of manuf. of Mars yellows. All of these consist of Fe hydrates or oxides pptd. on a base of ZnO, CaSO_4 , clay, etc.

F. A. WERTZ

The poisoning action and dangers of organic solvents and their prevention. ANON. *Farbe u. Lacke* 1925, 422-3, 433-4.—A review of the toxic effects of alcs., ketones, turpentine, benzene, C_6H_6 , chlorinated and hydrated hydrocarbons, CS_2 , etc., of the fire hazards involved, and of preventive measures.

F. A. WERTZ

Cellhorn (zellhorn), Cellon, cellulose ester lacquers. III. C. R. HALL. *Farbe*

u. Lacke 1925, 424.—A review of cellulose ester products, of solvents employed, of aviation dopes, etc. F. A. WERTZ

The chemistry of drying oils. II. G. W. ELLIS *J. Soc. Chem. Ind.* **44**, 469-72, 486T(1925); cf. *C. A.* **19**, 3380, 3603.—Linoxyn appears to develop aldehydic structures on treatment with H_2O , as shown by the marked reaction with phenylhydrazine and Schiff's reagent. It probably contains a considerable proportion of its compn. in the form of a hexanone ring structure; and probably contains a number of OH groups. When linseed oil is oxidized under dry conditions, no appreciable amt. of H_2O -sol. acid products results. The volatile products formed during oxidation of linseed oil in dry oxygen or air at ordinary temps. were detd. by absorption in H_2SO_4 and in KOH by a variety of methods. There is little justification for regarding more than a small portion of the volatile products as due to the primary oxidation process, and this small proportion may represent a reaction secondary to that which forms linoxyn. At 0° and in darkness, linseed oil does not appreciably oxidize in dry O at a pressure of 2 atm. In dry O, linoxyn is comparatively stable but in the warmth of direct sunlight, it absorbs O and undergoes appreciable decompn., forming a thick yellow oil and evolving CO_2 . This is perhaps the reaction which gives rise to the volatile products usually obtained. All expts. are described in detail. F. A. WERTZ

The drying of fatty oils. A EIBNER *Farben-Ztg* **30**, 3055-6; *Farbe u. Lacke* 1925, 457. —A review. F. A. WERTZ

Wood oil and the possibilities in its treatment. H. RASQUIN. *Farbe u. Lacke* 1925, 420-1, 418.—A brief review is given of the patents claiming to effect the production of a heat bodied wood oil, similar to "stand oil," without the formation of a gel. Preliminary expts. were made in heating mixts. of raw wood oil and of wood oil heated 2 hrs. at 200° , with various solvents under reflux condensers, until the consistency of the soln. after cooling approached that of varnish. The films produced by these varnishes were then examd. for drying, freedom from the frosting effect characteristic of raw wood oil, hardness, gloss, etc. Those produced from solns. in turpentine and in other solvents with b. p. around 165° showed that the necessary degree of polymerization had not yet been reached to produce a clear hard, glossy film; but those produced from decalin, b. $190-200^\circ$, produced good films. The method is suggested for research to det. its com. manufg. possibilities. F. A. WERTZ

Esterification. ANON. *Farbe u. Lacke* 1925, 421.—A brief review of the esterification of rosin glycerol to produce ester gum. F. A. WERTZ

The production of printing inks. HANS HADERT. *Farbe u. Lacke* 1925, 419-51.—A review with formulas. F. A. WERTZ

The inter-esterification on heating of fatty acid glycerides with resin acids. K. PISTOR. *Farben-Ztg* **30**, 3056-7; *Farbe u. Lacke* 1925, 156.—Abietic acid, colophony, run Congo gum, acid albertol and neutral albertol were heated separately with tristearin, and with refined linseed oil, with variations in the proportions used and in the time, and temp. of heating. The free acids were then sep'd by distn. *in vacuo*, and the quantity of free fatty acids found was taken as a measure of the interchange from fatty acid glyceride to resin acid glyceride. The tabulated results show that the reaction follows the laws of mass action and depends on time and temp. of heating. In the manuf. of oil-resin varnishes very little inter-esterification takes place because of the short period of heating. F. A. WERTZ

A new method for the determination of the color of resins, varnishes, oils, etc. E. FONROBERT. *Farben-Ztg.* **30**, 3057(1925).—Aq. solns. of I in KI form the best color standards for these products. It is proposed that the color number of the substance be the mg. of free I in 100 cc. of I-KI soln. of the same color. The detn. is made by comparing in transmitted light, a column of definite height of the sample with a column of variable height of the I-KI soln. and then titrating the free I present. All measurable color nos. will range from plus 4 to plus 1000. The color numbers for the present standard American rosin grades are tabulated. F. A. WERTZ

The alleged volatility of bakelite resins with spirit vapors. JOH. SCHEIDER. *Z. anorg. Chem.* **38**, 904-5(1925).—The volatility of bakelite resins with the solvent vapors in bakelite varnishes cannot be confirmed: the sol. resins are entirely non-volatile at 100° . If the varnish applications are heated to 140° , the sol. "A" resin is transformed to the insol "C" resin with accompanying losses of H_2O and phenol products resulting from the polymerization. These products might produce the deposits noted on the walls of drying ovens, but they are not produced to the extent previously reported by v. d. Heyden & Typke (*C. A.* **19**, 2277). F. A. WERTZ

Waterproof paint. J. GALLIAN. U. S. 1,560,075, Nov. 3. A paint adapted for

use on cement or brick walls is formed of white lead, ZnO , BaSO_4 , turpentine, damar gum, beeswax, KNO_3 and linseed oil.

Paint- and varnish-remover. C. A. KING and C. M. WARLICK. U. S. 1,556,694, Oct. 13. A coating of paint or varnish to be removed is treated with a concd. soln. which may be formed from H_2O , NaOH and $\text{Ca}(\text{OH})_2$, with or without $\text{K}_2\text{Mn}_2\text{O}_8$ and is then sprinkled with a small amt. of H_2O . Chem. action is then allowed to take place before the coating is removed.

Red lead. H. HOCKING. U. S. 1,556,820, Oct. 13. See Brit. 220,609 (C. A. 19, 709).

Varnish. S. P. ASHMORE. U. S. 1,557,961, Oct. 20. English rosin 1 lb., Na salicylate 3 oz., ether 2 oz., a drier such as japan drier 1 pint, a drying oil vehicle such as boiled linseed oil 1 pint, turpentine 1 pint and MeOH 1 pint.

Synthetic resin varnish. C. ELLIS. U. S. 1,557,519, Oct. 13. A varnish base is formed from linseed oil or other drying oil and an oil-sol. cresol-S resin.

Decorating surfaces with copal and shellac varnishes. G. L. GUENOT and G. MAURICE. U. S. 1,561,324, Nov. 10. Surfaces such as those of walls or furniture are treated with copal varnish, formed with turpentine as solvent, and before the varnished surface is dry a shellac varnish, contg. alc., is applied, which serves to produce a contrasting mottled finish.

Solvent and vehicle for use with varnishes and similar compositions. C. D. HOCKER. U. S. 1,558,880, Oct. 27. Castor oil, gelatinized with copal, is treated with a free fatty acid, e. g., fatty acids from Chinese wood oil.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL.

The detection and estimation of small amounts of chromium in fats. A. O. SNODDY. *J. Oil & Fat Ind.* 2, 20-5(1925).—Fats are sometimes bleached with Cr salts. Therefore detn. of traces of Cr in them is desirable. The following colorimetric method for detecting and estg. small amts. of Cr by means of diphenylcarbazide has proved satisfactory. Burn carefully 200 g. of fat in a Pt dish and ignite to ash preferably in a muffle to avoid losses which are apt to occur over free flame. Add 5 g. of an equimol. mixt. of Na_2CO_3 and K_2CO_3 , heat to fusion to convert all Cr^+ to Cr^- , cool and dissolve the melt in H_2O , faintly acid with HCl, making up to 200 cc. in the case of fats having about 1 part per million Cr. Compare in Nessler tubes the color obtained by mixing an aliquot of this soln. with 5 cc. of 20% HCl after dilg. to definite vol., and adding 1 cc. of diphenylcarbazide soln. with various dilns. of a standard $\text{K}_2\text{Cr}_2\text{O}_7$ soln. made with approx. the same concn. of Na_2CO_3 and K_2CO_3 , and treated the same as the unknown. The diphenylcarbazide soln. is made by dissolving 0.1-0.2 g. of the reagent in 10 cc. glacial AcOH and dilg. the 100 cc. with 95% EtOH. The violet color formed by the reaction reaches a max. in less than 10 min. and varies directly with the amt. of Cr present. Small amts. of Fe, Al, Cu and Si, which occur in the ash of fats, do not interfere in the reaction.

H. S. BAILEY

Iodine-bromine number via L. W. Winkler. K. SCHEFFLER. *Pharm. Zentralhalle* 66, 533-8(1925).—A series of expts. is described showing that the Winkler method is far more simple and quicker than that of v. Hübl, being only about $1/8$ as expensive and yielding satisfactory values in the case of fats with I no. as high as 120. In the case of higher values than that cited the comparative findings were only moderately in agreement.

W. O. E.

Modern processes for refining oil. E. WEISS. *La nature* 53, ii, 219-23(1925); cf. C. A. 19, 2570, 3167.—An illustrated description of the deacidification, decoloration and deodorizing of vegetable oils.

C. C. DAVIS

Some analytical data on the oils from sharks and rays. ALLEN ROGERS. *J. Am. Leather Chem. Assoc.* 20, 497-8(1925).—Analyses of oils from the livers of sand shark, tiger shark, hammerhead, nurse shark, devil fish and saw fish.

J. A. WILSON

Detection of coconut and palm kernel oils in cacao butter and fat from milk chocolate. W. F. BAUGHMAN. *J. Assoc. Official Agr. Chem.* 8, 703-5(1925).—Sapon. 5 g. of sample with 10 cc. of KOH (25 g. KOH in 200 cc. EtOH), evap. the alc., add 5 cc. H_2O , evap., dissolve in 10 cc. H_2O , cool, add with stirring 100 cc. of satd. NaCl, let stand 15 min. with occasional stirring, filter on a Büchner funnel; to 100 cc. of the filtrate add with stirring 100 cc. of satd. NaCl, let stand 15 min., filter and slightly acidify the filtrate with HCl. With pure cacao butter the soln. will remain clear when acidi-

fied; with fat from milk chocolate it will become faintly turbid, and if coconut or palm kernel oil is present it will become turbid or milky. A. PAPINEAU-COUTURE

Method for the rapid and accurate determination of fat in cacao products. H. A. LEPPER AND H. C. WATERMAN. *J. Assoc. Official Agr. Chem.* 8, 705-10 (1925).—Detn. by continuous extn. with anhyd. Et_2O is inaccurate owing to extn. of theobromine and a trace of resin-like material, and troublesome owing to required preliminary drying and possibility of the sample running through the filtering medium. Petroleum ether exts. saponifiable glycerol esters, phytosterols and lecithins, but the 2 latter may be regarded as normal fat constituents. L. and W. describe in detail a method consisting essentially in exhausting the sample with petroleic ether (usually 10 extns.) in a Knorr tube and collecting the ext. in a tared Erlenmeyer flask under a filtering bell jar, evapp. the solvent and drying to const. wt. at 100° . A. PAPINEAU-COUTURE

Report of Smalley Foundation Committee of A. O. C. S. on check meal samples. H. C. MOORE. *J. Oil and Fat Ind.* 1, 12-8 (1924).—The results of 78 chemists who detd. gasoline ext. and NH_3 on 30 samples of cottonseed meal are summarized and discussed. H. S. BAILEY

Waxes. A new chemical index. R. ROSSEAU. *Bull. sci. pharmacol.* 32, 449-63 (1925).—This paper is an abridgement of a 78-page thesis on waxes, particularly the vegetable waxes, in which the subject is considered from the standpoints of histologic botany and of chemistry. The detn. of the acetyl index by the method of Leys is emphasized. The ratio of (acetyl index of ales. esterified) to (acetyl index of total ales.) was found to be practically const. for the same kind of wax, and, therefore, of value in the detn. of the purity of a given sample. L. W. RIGGS

Report of Soap Stock Committee of A. O. C. S. for 1924. A. A. ROBINSON. *J. Oil and Fat Ind.* 1, 18-23 (1924).—Corn oil and soy bean oil soap stocks were analyzed for unsaponifiable, free oil and total fatty acids by 7 collaborators. Details of methods used and results obtained are given. The drying of the total fatty acids in CO_2 is not necessary to prevent oxidation, even with the easily oxidized acids of corn and soy bean oils. H. S. BAILEY

Effects of age on soap solutions. ROSALIE M. COBB. *Ind. Eng. Chem.* 17, 1134-5 (1925).—The resistance of sodium oleate-Nujol emulsions to salting out by NaCl varies periodically with the age of the soap soln. The aging effect is manifest to greater degree on lather values of commercial soaps. R. M. COBB

Colored goods and the laundry. GEO. W. JOHNSON. *Am. Dyestuff Rept.* 14, 681-5 (1925).—The modern methods of laundry works founded on research supported by the Laundryowners' Nat. Assoc. are described. Goods as received in the family bundle are divided into 12 classes and the directions for the treatment of each class are given. These directions show the kind and quantity of soap or other chemical if any are to be used, also the number, vol., and temp. of the baths used. The factor of temp. is too often ignored in unscientific laundering. The dyer of goods which are to be laundered should know the conditions of laundry work and select dyes capable of meeting those conditions. L. W. RIGGS

Apparatus for approximate or comparative melting points of fats, waxes and petroleum (STEVENS) 1.

Refining vegetable oils. C. H. HAPGOOD and G. F. MAYNO. U. S. 1,560,084, Nov. 3. See Brit. 228,889 (C. A. 19, 3028).

Soap. A. WELTER. U. S. 1,560,626, Nov. 10. Fatty acid soap stock or other fatty acids are mixed, at a temp. approx. their m. p., with water-free alk. carbonate such as Na_2CO_3 in double the quantity required for the complete saponification of the fatty acids so that the excess carbonate is sufficient to absorb the CO_2 resulting from the saponification and produce a soap contg. no stronger alkali than NaHCO_3 .

Shaving soap. C. A. SIPE. U. S. 1,558,642, Oct. 27. The reaction products of "lye," fat and H_3BO_3 are mixed with smaller quantities of acetanilide and H_2O_1 .

Glycerol soap. W. T. GUSSINKLO. U. S. 1,550,540, Aug. 18. A hard soap is formed from coconut oil, NaOH soln. and glycerol, the glycerol constituting at least 75% of the vol.

Detergent mixture. H. M. HECKMAN. U. S. 1,559,960, Nov. 3. A compn. adapted for cleaning terra cotta walls, etc., comprises soap and blast furnace slag which has been granulated by introducing it into H_2O while hot.

Porous soap-tablets containing bran, oatmeal, linseed meal, sawdust or other absorbent material. C. J. ATKINSON. U. S. 1,556,576, Oct. 13.

Composition for cleaning grease or paint from fabrics. C. ELLIS. U. S. 1,557,520, Oct. 13. A mixt. of C_2HCl_3 80-75 and $EtOAc$ 15-20%, substantially free from fats, soaps and waxes.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

• **Report on meetings of technical advisers in the Java sugar industry, April 22 and 23, 1925.** ANON. *Arch. Suikertnd* 33, Part 4(1925), cf. *C. A.* 19, 2754. **Joint meeting of chemical and technical sections, 1-120 pp.** **Meeting of chemical sections, 121-35 pp.**—A round table discussion on the same topics as at the previous meetings, with the following new agenda: steam turbines, and new juice strainers. F. W. Z.

• **Results of Claassen's methods of boiling and crystallization.** E. O. VON LIPPMANN. *Deut. Zuckertnd* 50, 681-5(1925).—I. has used these methods in refinery operation since 1906. Third liquor, consisting of affination sirup and of the sirup from II b product, is used, the mixt. dild. to 65 Brix, filtered according to Soxhlet, brought to the proper temp., and taken to the pan. It is essential that the liquor be absolutely clear and always of the same temp. A part of the sirup from the product preceding II b is also worked up in the same manner, in varying quantities depending on market conditions. The polarization purities varied greatly from yr. to yr., from 91.7 to 94.7, av. 92.7 for II b liquor, from 81.2 to 86.7, av. 85.0 for III liquor, and from 59.5 to 66.6, av. 64.3 for molasses. The sucrose purities are lower than these, but run more or less parallel with the apparent purities. The wide annual variations, due to quantity and nature of non-sugars, are partly caused by weather conditions, but largely influenced by the quality of the work in the raw sugar factory. It was definitely shown that the high purity of the molasses obtained in certain yrs. could not be further reduced, and conversely that low purities are no indication of exceptionally good work. Prolonged stirring of the magma is not advisable, especially in yrs. of high raffinose content, because it tends to break up the crystals and leads to losses in purging. The av. compn. of product II b (a) and III (b) was as follows: Dry substance (a) 99.5, (b) 99.1; polarization (a) 98.5, (b) 97.0, ash (a) 0.6, (b) 0.7, org. (a) 0.6, (b) 1.4. F. W. ZERBAN

Temperature and analytical changes in sugar liquor during bone black filtration. H. I. KNOWLES. *Ind. Eng. Chem.* 17, 1151-3(1925). A char filter was equipped with 9 sampling pipes and 4 of them had thermometers, as shown in a diagram. Filtration tests were made, mostly with 2nd liquor, through char of known mesh distribution, the temp., color, and compn. of the effluent being detd. The temp. changes at the side and in the center of the filter during an entire cycle are shown in a graph. After contact of char and liquor there was noted no additional removal of color. At the side of the filter the decolorization and removal of non-sugars are poor, on account of the low temp. At the center there is actually production of color, because the temp. rises too high; but removal of non-sugars there is also slight. Various explanations are offered for this. Analyses of the different portions of the effluent show that at least $\frac{1}{3}$ is delivered at the side. Two independent tests showed that the mesh size of the char is largely responsible for differences in efficiency. Besides the factors named, time and p_H are also important, especially with sugars that are poorly buffered. Washed sugar liquor should issue from the filter with a p_H of not less than 6.8, while with 2nd liquor even 6.5 appears safe. F. W. ZERBAN

Physical examination of sugar juices. K. R. LINDFORS. *Ind. Eng. Chem.* 17, 1155-6(1925).—Analyses of sugar factory products by the usual methods do not furnish reliable information on the efficiency of filtration and other factory processes. I. has devised several phys. methods which serve this purpose and are easily carried out. Surface tension, which is roughly inversely proportional to % of gums, is measured by Du Noüy's app. (*C. A.* 18, 2822). The viscosity of green sirup, 2nd fillmass and molasses is detd. by means of a jacketed 100 cc. pipet, at 20° or corrected to 20°, pure sucrose soln. of varying concn. being used as standard. "Viscosity Brix" of a product is defined as the Brix which a pure sugar soln. showing the same viscosity would have. "Viscosity purity" is based on "viscosity Brix." An increase in the viscosity purity denotes a removal of gums, and *vice versa*. "Visible" turbidity, that observable in diffuse light, is detd. by comparison in a Jackson turbidimeter with a standard prepd. by dispersing bentonite (*C. A.* 19, 628) in water with gum arabic. "Colloidal" turbidity is estd. in a Horne turbidiscopes (*C. A.* 18, 1927) by comparison with a more dil. bentonite prepn. colored with caramel. A slit of variable thickness in the turbidiscopes permits more accurate comparisons to be made. An example of the application of

these methods is shown. They may also be used in deciding the point at which Steffen molasses should be discarded. The methods are described in detail, and discussion is invited.

F. W. ZERBAN

Reheating of sirup. PHILIPPE CANTIN. *Rev. agr. Maurice* 2, 524-6 (1925).—Heating the sirup to 80° after the addition of acid phosphate, as advocated by Béranger (*C. A.* 19, 1960), has not given good results. It was found necessary to keep within 65-70° to avoid excessive inversion. Even at the lower temp. some inversion takes place, but the advantages of the method outweigh the disadvantages from the com. standpoint. Better sugar is produced; it washes up better in the centrifugals; and there is less remelt sugar.

F. W. ZERBAN

The Lafeuille crystallizer. H. SORNAY. *Rev. agr. Maurice* 2, 520-4 (1925).—This app. is described as a "tubular, rotary crystallizer," without further details. It is claimed that it reduces the time of crystn. of high purity massecuites to 3 hrs., and of low purity massecuite to 24 hrs. instead of 8 days or more as at present. In spite of this, uniform grain, without false grain, is obtained. Yield and quality of sugar are better, less after-product has to be worked up, and 1 crystallizer will replace 3 of the older type of the same size. It can be worked under vacuum. A chart shows comparative exptl. data on Brix, temp and purity for the new and old type, for a refinery. Similar results are predicted for the raw sugar factory.

F. W. ZERBAN

Mill equipment in the year 1924 (Java). G. E. FERGUSON. *Arch. Suikerind.* 33; *Mededel. Proefstation Java Suikerind.* No. 10, 311-74 (1925).—A series of tables showing, for each single mill, maker, dimensions, use of hydraulics, gear ratio and data on driving engine; it is preceded by a summary and discussion.

F. W. ZERBAN

Preliminary operations before centrifuging and the centrifuging operation itself. ALFRED SALOMON. *Centr. Zuckerind.* 33, 1309-12 (1925).—A very general qual. discussion.

W. L. BADGER

Messchaert grooves. L. BAISSAC. *Rev. agr. Maurice* 2, 526-8 (1925).—Detailed dimensions of Messchaert grooves are given for 2 tandems in Hawaii, and recommendations are made for the construction and installation of efficient scrapers.

F. W. ZERBAN

Purification of caramel. A PRINS. *Arch. Suikerind.* 33, 910 (1925).—The fine black ppt. which forms in the com. prepn. of caramel cannot be filtered off through a centrifugal screen, but is retained completely by a layer of sugar which has just been purged in a centrifugal. The small amt. of sugar dissolved by the caramel causes no trouble in its subsequent drying.

F. W. ZERBAN

Brix determination in molasses. I. JOHANSEN. *Arch. Suikerind.* 33, 1008-10 (1925).—The present method (in Java) of detg. Brix of molasses, after dilg. 1:10, either by spindle or pycnometer, is not satisfactory. The ordinary Westphal balance is not accurate enough. A more exact balance, based on the same principle, may be constructed from an ordinary sugar balance. One arm is removed entirely and replaced by a plummet made from an old elec. light bulb. The fitting of the bulb is removed, the wires are bent into a loop, and the hole in the neck of the lamp is filled with sealing wax. Then the point of the lamp is broken off carefully under Hg. about 550 g. of Hg is permitted to run into the bulb, and then the opening is sealed again in the flame. The vol. of the plummet at the standard temp. is detd. from its wt. in air and in H₂O. The sp. gr. of the molasses soln. is calcd. from $(l-m)/k$, where l is the wt. of the plummet in air, m its wt. in the molasses soln., and k its vol. A table may be constructed giving directly the Brix corresponding to a given wt. of the plummet in molasses soln. The app. is illustrated.

F. W. ZERBAN

Cooling of the massecuites and its effect on the boiling scheme and on the exhaustion of the molasses. G. E. VAN NES. *Arch. Suikerind.* 33; *Mededel. Proefstation Java Suikerind.* No. 8, 305-24 (1925).—In the boiling method at present practiced in Java the A-massecuite gives a sugar yield of about 60%, but the B-massecuite only 14%, and the C-massecuite 41%. This low recovery in the last 2 is undoubtedly due to the increased viscosity of the massecuites by prolonged heating. It is proposed to cool the massecuites, except that yielding molasses sugar, to 40° before purging. It is calcd. that by this method the no. of massecuites could be reduced from 4 to 3, the purity of the run-off from A massecuite being reduced to about 59, of the run-off from B-massecuite to 41.5, and the purity of the molasses to 25.1. It will, of course, be necessary to dil. the massecuites before purging, and this can be done in practice by the hot purging of 1 out of every 3 strikes, the resulting run-off being used for dilg. the other 2. By this scheme the capacity would be increased 12% and the com. sugar yield 1.18% on the dry substance. However, more molasses sugar would also be produced, and to overcome this difficulty it is proposed to boil one A-strike as usual, purging at 65°, then boil a 2nd strike, drop about 20% of its draw in run-off from the 1st strike,

and then proceed as indicated before. A molasses purity of only 23, and an increased com. sugar yield of 1.73% may be expected by this method of boiling. All the calcs. are given in detail, and the boiling scheme is shown in a graph. The proposed method has not been tried yet.

F. W. ZERBAN

Equipment for weighing and dumping cane in Java sugar factories. G. E. FERGUSON. *Arch. Suikerind.* 33; *Mededeel. Proefstation Java-Suikerind.* No. 9, 325-39 (1925).—A summary, in form of tables, for 174 factories, with brief discussion.

F. W. ZERBAN

Occurrence of sereh disease in mill and plant cane (Java), in 1925. J. KUYPER. *Arch. Suikerind.* 33; *Mededeel. Proefstation Java-Suikerind.* No. 11, 375-90 (1925).

F. W. ZERBAN

Observations on the Sachs-Le Docte method, used in titer contracts for determining the sugar content of beets. E. PARISI. *Star. sper. agrar. ital.* 57, 336-42 (1924).—Low results are obtained if, instead of the prescribed 4% soln. of basic lead acetate in ordinary water, a soln. of acetate to which powdered Ba(OH)₂ has been added is used.

ALBERT R. MERZ

Recovering diatomaceous earth after use for clarifying sugar solutions (U. S. pat. 1,561,042) 18.

Separating sugar from molasses. C. G. LEONIS. U. S. 1,558,551, Oct. 27. Molasses, *c. g.*, the discard molasses from the Steffen process, is dried on a belt conveyor or otherwise pulverized and treated with 1¹/₂ to 2 times its wt. of 99¹/₂% HOAc for 2-4 (usually about 6) hrs. at a temp. of 15-30° to effect a "precipitation" of the sugar. Mother liquor surrounding the sugar crystals is removed by washing with a solvent such as alc., toluene or C₆H₆, in which the sugar is insol.

Dextrose from starch. A. W. H. LENDERS and J. M. WIDMER. U. S. 1,556,854, Oct. 13. The content of insol. protein in starch is reduced until it is not substantially in excess of 0.35% (based on dry wts.) and substantially all the sol. protein is removed. The starch is then converted by acid hydrolysis to the glucose state, the liquor is neutralized in the presence of H₂PO₄ and filtered, treated with tannic acid to coagulate solubilized albuminoids, subjected to an adsorption filtration, *c. g.* with C or bone char, converted to a dextrose content of more than 90%, neutralized and treated to effect the solidification and crystn. of the entire body of converted liquor.

Dextrose hydrate. W. B. NEWKIRK. U. S. 1,559,176, Oct. 27. A dextrose hydrate which is not detrimentally affected by ordinary exposure to atm. moisture is prepd. by partially dehydrating a dextrose hydrate contg. the normal proportion of H₂O of crystn., *e. g.*, by exposure to currents of heated air in revolving drums until the H₂O content is reduced from about 10% to about 6%.

Continuous thickening and filtration of limed and carbonated sugar juices or similar materials. A. L. GENTER. U. S. 1,560,796, Nov. 10. Mech. features.

29—LEATHER AND GLUE

ALLEN ROGERS

Report of work in progress at the Darmstadt Institute for Leather Chemistry. E. STIASNY. *Gerber* 51, 165-7, 173-6 (1925).—A study of antiseptics for use in soaking has shown that ZnCl₂ is very effective, and has no bad effect on the leather. Attempts to carry out *unhairing* by means of *pepsin* were fruitless; pepsin attacks collagen more readily than the malpighian layer. The action of *trypsin* on collagen, promoted by neutral salts, probably plays a part in *bating*. By the action of *pepsin* on collagen a high-grade gelatin can be produced. *Chrome tanning* experiments have shown that the sign of the charge on the Cr-complex is immaterial. Negatively charged *sulfite-chrome* and *oxalo-chrome* complexes are fixed slowly but firmly by collagen, and the resulting leather has many desirable properties. By adding increasing amounts of sulfite to Cr(OHSO₄) soln., the pptn. value is first decreased, then increased, and becomes infinite when 1.5 mols. sulfite are added to 1 mol. Cr(OHSO₄). At very high sulfite concns. tanning is inhibited, but strong tanning action is manifested even when pptn. of Cr cannot be brought about by any amt. of alkali. Under suitable conditions very large amts. of Cr (15-18%) can be fixed, producing a very firm leather, without damage to the grain. A study of the relation between size of particles in vegetable tan liquor (as detd. by salting out expts.) and tanning power has shown that as the degree of association decreases the tanning power increases, to a certain point, after which it decreases with further decrease in molecular complexity. The material salted out of

tan liquors is not comparable with that deposited from lyophobic sols since no permanent sepn. into particles of definite size limits can be effected, the pptd. larger particles giving particles of all sizes on redispersion. A method for analyzing *sulfonated oils* based on a sepn. into 2 fractions—(1) sulfonated oil, sol. in EtOH (80%), insol. in gasoline, and (2) unsulfonated oil, insol. in EtOH (80%), sol. in gasoline, has been worked out and applied to the study of the sulfonation of different oils. The optimum conditions for emulsification, with sulfonated oils as emulsifying agents, are found at $p_H = 7.7$. Pure *polypeptides* react with acids only through their amino groups; with alkalies only through their carboxyl groups at $p_H < 10.5$, but at higher p_H values the peptide linkage also reacts with alkali.

H. B. MERRILL

Determination of moisture in leather. F. P. VEITCH, *et al.* *J. Am. Leather Chem. Assoc.* 20, 504-5(1925); cf. C. A. 19, 2573. —Discussion J. A. WILSON

Some suggested tests on shoe upper leather. ALLEN ROGERS. *J. Am. Leather Chem. Assoc.* 20, 495-7(1925).—The tests suggested for chrome upper leather are the stitch tear, tensile strength and boiling test. J. A. WILSON

Analysis and specifications for miscellaneous materials. C. R. OBERFELL, *et al.* *J. Am. Leather Chem. Assoc.* 20, 503-4(1925), cf. C. A. 19, 1962. —Discussion J. A. WILSON

Hide and leather imperfection caused by follicular mange. R. W. FREY, *et al.* *J. Am. Leather Chem. Assoc.* 20, 507-9(1925); cf. C. A. 19, 2884. —Discussion J. A. WILSON

Destructive and preservative effect of neutral salts upon hide substance. A. W. THOMAS AND S. B. FOSTER. *Ind. Eng. Chem.* 17, 1162-4(1925).—Neutral sulfates retard hydrolysis of hide substance while alkali halides accelerate it. Thus Cauber's salt is a far better preservative for hides than common salt, which is being used almost universally. J. A. WILSON

Action of ultra-violet light on hide protein. A. W. THOMAS AND S. B. FOSTER. *J. Am. Leather Chem. Assoc.* 20, 490-4(1925).—When subjected to ultra violet rays for several weeks, hide powder assumed a canary yellow color and about 28% of it was rendered sol. in water, giving a yellow soln. The irradiated collagen showed a much smaller capacity to combine with hemlock tannin than ordinary collagen, but no difference was found in capacity to combine with quinone, indicating a difference in nature of vegetable tanning and quinone tanning. Direct measurement of plumping power of tan liquors. R. E. PORTER, *et al.* *J. Am. Leather Chem. Assoc.* 20, 498-501(1925), cf. C. A. 19, 2279. —Discussion J. A. WILSON

A straight-line function in the tan wheel. R. M. COBB, *et al.* *J. Am. Leather Chem. Assoc.* 20, 505-7(1925); cf. C. A. 19, 2572. —Discussion. J. A. WILSON

Utilization in the chemical industry of raw materials from sharks (TANDLER) 13.

Tanning. J. R. BLOCKEY. U. S. 1,557,011, Oct. 13. The degree of swelling of pH is regulated by a preliminary treatment with a soln. such as a dil H_2SO_4 soln., the acidity of which is maintained substantially the same as that of the tanning liquor by the addn. of a neutral salt, e. g., NaCl. Cf. C. A. 19, 3614

Decreasing hides and skins by use of volatile solvents. A. J. HANGLIN. U. S. 1,556,598, Oct. 13. The material is heated in a closed drum with a solvent such as naphtha to develop pressure at a temp. sufficiently low as not to injure the hides or skins, and, after agitation, while under pressure, the soln. or emulsion of solvent, grease and H_2O formed is withdrawn.

Tanning. H. YOUNG. U. S. 1,551,000, Aug. 25. Hides are subjected to a tanning

mixt. composed of terra japonica $1\frac{1}{2}$ and pulverized alum $\frac{1}{2}$ lb. and H_2O for several days, the hides being removed for airing at intervals.

Tanning composition. C. IMMERHEISER and H. WOLFF. U. S. 1,557,844, Oct. 20. By the treatment of crude $C_{14}H_{10}$ or "anthracene waste" with H_2SO_4 and adding Cl, NaOCl or oxalic acid a sulfonated crude anthracene is obtained which slowly produces a pure brown coloration on hides suspended in its dil. acid soln. Formaldehyde also may be added.

Tanning composition. G. W. LANGLEY and A. A. HOWELL. U. S. 1,557,174, Oct. 13. A mixt. of ext. of wild cherry bark, ext. of sumac gum, gambier and H_2O .

Tanning substances. O. SPENGLER and A. THURM. U. S. 1,550,589, Aug. 18. Tanning compns. which are dark hygroscopic powders sol in H_2O are produced by heating alicyclic acid sulfochloride or other arylsulfochloride at $160-200^\circ$ with phenol or other hydroxyaryl compds. without addition of condensing agents.

● **Glue globules.** A. OBERSOHN, W. WACHTEL, D. SAKOM and P. ASKENASY. U. S. 1,559,126, Oct. 27. A hot coned glue soln is sprayed under pressure to form drops which are cooled by passing through a cooling gas under pressure. Cf. C. A. 19, 1744.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Something about the drying and smoking of rubber. R. RIEBL. *Arch. Rubbercultuur* 9, 794-812(1925).—An address. F. H. YORSTON

Viscosity of rubber solutions. C. L. ABERNETHY. *India Rubber J.* 70, 775-83 (1925).—Various methods which have been developed for detg. the viscosity of liquids, particularly rubber solns., are described, with an extended discussion of the physics involved in the falling sphere viscometer. By the aid of the latter an exptl. study was made of the viscosity of rubber solns. In these expts. the variation in viscosity of rubber solns. with variation in concn. and with change of temp. at different concns. was detd. for 10-30% solns. and temps. of 10-60°. The results are given in tables and graphs. At a given temp. the abs. viscosity increases with the concn. at a slowly increasing rate up to 15% rubber, after which the viscosity varies directly with the concn. At all concns. the abs. viscosity in PhMe is less than that in C_6H_6 . The decrease in viscosity with increase in temp. is greatest in highly coned solns., the temp. effect becoming less and less with increase in diln. Likewise for a given concn. the change in viscosity for a given change in temp. becomes less and less as the temp. increases. Further work to derive a relation between viscosity and concn., in which the applicability of the logarithmic formula of Arrhenius (cf. *Z. physik. Chem.* 1887, 1, 285) as well as more recent ones was tested, shows that none of these log. formulas is applicable to rubber solns. But by plotting the sq. roots of the concns. against the logs. of the viscosities, straight lines are obtained, the relation $\eta_c = K e^{k\sqrt{c}}$ being derived, where η_c is the viscosity in C. G. S. units of a soln. contg. c g. of rubber in 100 cc. of soln., K and k are consts. and e is the base of the Napierian logs. Calcn. from the graphs shows K to be $e^{-6.102}$ for all temp. and k to be 2.413 at 10° and 2.176 at 60°. Extrapolation in turn shows the viscosity of milled rubber itself to be 22,400,000 and 2,290,000 C. G. S. units at 10° and 60°, resp. This ten-fold decrease in viscosity between 10° and 60° emphasizes the importance of accurate temp. control in any method for detg. the relative viscosity of rubber. Below 1% concn. Arrhenius' equation is valid, perhaps for the reason advanced by Hatschek for 2-phase emulsoid systems in general (cf. C. A. 7, 3873). Application of the method to solns. of raw unmilled rubber at 15.5° showed the following viscosity in C. G. S. units: 2%, 5.04; 3%, 35.63; 4%, 162.8; 5%, 464.4; 6%, 1577. In this case also, the new equation $\eta_c = K e^{k\sqrt{c}}$ was valid. Application of the latter to other published work, e. g., Me_2CO solns. of nitrocellulose (cf. C. A. 14, 3153) shows the validity of the new equation with solns. other than those of rubber. C. C. D.

Plasticity determination in crude rubber. IV. Difference between smoked sheet and pale crepe. O. DE VRIES. *Arch. Rubbercultuur* 9, 813-36(1925); (In English *Ibid* 837-43).—The av. d_{30} and II (cf. C. A. 19, 2281-2) for 13 crepes prepd. on a small mill were 1.395 and 0.070, resp. and for corresponding air-dried sheets 1.595 and 0.083. Accordingly crepe was the more plastic rubber. There was a smaller difference of about 0.1 between the d_{30} of crepes and of sheets prepd. on an estate by R. Riebl. A distinct plasticizing effect was noted on long maceration of the rubber. Great diln. of the latex before coagulation also gave a definite decrease in d_{30} . No marked change in plasticity could be ascribed to rolling into sheets (compared with air-drying of fresh

or matured coagulum without mechanical treatment), to the use of H_2O on the rolls, to soaking freshly rolled sheets in H_2O , to heating the wet rubber or to smoking. These conclusions refer to rubber tested within a month of its prepn. under which conditions there was no important difference between fresh crepe and sheet. An earlier statement that crepe was the harder rubber was based on an examn. of a no. of samples some of which had hardened on keeping. The change in the plasticity of stored rubber is being studied.

F. H. YORSTON

A simple control test for the distribution of sulfide-containing ingredients in rubber goods. ANON. *Gummi-Ztg.* 40, 277(1925).—A preliminary communication. Sulfides decomposable by acids in rubber goods can be detected very easily by the appearance of colored spots when the rubber is treated with an acid and the H_2S acts on AgBr or $HgCl_2$. As a simple technic, a smooth fresh surface of rubber is pressed for 3-5 min. against AgBr paper which has been unattacked by light and which has just been steeped in 30% H_2SO_4 . The paper is then immersed in an acid-fixing bath, washed and dried. A fresh surface of rubber is necessary, since with old rubber oxidation of the original surface obscures the test. The method shows the uniformity and the degree of dispersion of the ingredients. Reproductions of rubber samples contg. lithopone are given.

C. C. DAVIS

Aging tests on rubber coagulated with acetic acid and *p*-nitrophenol. II. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 496-8, 565-7(1925); cf. *C. A.* 19, 3616.—In using $p-O_2NC_6H_4OH$ as a mold preventive it is now found best to dissolve an amt. equal to 0.03% of the latex in the HOAc used for coagulation. Samples of sheet prepd. with this soln. cured, in a rubber-S mixt., about 10% faster than did the controls. A specimen which was vulcanized for 3 hrs. and was over-cured deteriorated greatly after 3 days aging at 70°, while the control reached the same stage in 4 days. A specimen cured 2 hrs. was at first somewhat stronger, but after aging for 6 days was somewhat weaker, than the control. Samples vulcanized for 105 and 120 min. reached the state of cure of controls vulcanized for 120 and 135 min., resp., and they deteriorated at practically the same rate as did the controls during aging for 210 hrs. The difference in rate of cure of $p-O_2NC_6H_4OH$ prepd. rubber and ordinary rubber was greater in a mixt. contg. ZnO but no added org. accelerator, probably because of the destruction of part of the fatty acids in ordinary rubber by molds.

F. H. YORSTON

Smoked sheet rubber coagulated with acetic and formic acids containing *p*-nitrophenol. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 612-3(1925); cf. preceding abstr.—Satisfactory vulcanizates were prepd. from samples which had been coagulated with 1% solns. of HOAc and of H_2CO_2 contg. $p-O_2NC_6H_4OH$.

F. H. YORSTON

Report on further experiments on the spotting of crepe rubber. W. BROWN. *Bull. Rubber Growers' Assoc.* 7, 522-32(1925); cf. *C. A.* 19, 2144.—Since fungi invade dry rubber only slowly, their behavior was more conveniently studied on strips which had absorbed about 25% H_2O by soaking at 47°. A *Penicillium* which had been isolated from crepe produced spotting on this rubber without the addn. of any nutrient. Very rapid spotting took place when the rubber was inoculated with a *Fusarium* in the presence of traces of NH_4 salts. The last of many washings from a piece of crepe contained enough nutrient to stimulate distinctly the germination of spores. Extn. of rubber with cold acetone removed much nutrient, since it reduced spotting to an extent for which the lessened swelling of the rubber in H_2O could not account. Spotting was most rapid at 30° and was very slow at 35°. Neither fungus germinated at 38°, and the spores of the *Fusarium* were killed by exposure to this temp. for 4 days. An increase of 5° in the temp. of the drying sheds should prevent spotting, both by retarding germination and by increasing the rate of drying. A concn. of 0.01% $p-O_2NC_6H_4OH$ in neutral or faintly acid soln. prevented the germination of both fungi.

F. H. YORSTON

Determination of balata in balata-rubber mixtures. J. T. CHARLSON. *India Rubber World* 72, 470(1925).—Correction (cf. *C. A.* 19, 1967). For "cool to 12°," read "cool to -12°."

Latex. Insecticide preparation for combating plant parasites (DITMAR) 15. Manufacture of balloon fabrics (Dambroise) 25. Recovery of volatile solvents (LUTINGER) 13. Cement containing resin and rubber (U. S. pat. 1,561,095) 18.

Rubber composition. G. W. ACHESON. U. S. 1,560,132, Nov. 3. A solid inorg. substance such as china clay is deflocculated and the dry deflocculated material is

mixed with a rubber soln. and pptn. of the rubber is then effected by use of acetone or equiv. organic liquid. The rubber mixt. thus formed, after sepn. from associated liquid, is adapted for working or further blending, etc.

Rubber composition. L. R. KLUG. U. S. 1,550,968, Aug. 25. A compn. adapted for making mats, jars, etc., is prepd. by mixing scrap and reclaimed rubber with S, and adding "uncured friction."

"Compounding" rubber. C. C. LOOMIS and H. E. STUMP. U. S. 1,558,688, Oct. 27. Particles or ingredients such as clay, S, ZnO or lampblack which are subsequently to be mixed with rubber are preliminarily given a thin coating of rubber, *e. g.*, by treatment with ammoniacal latex and then with $Al_2(SO_4)_3$.

Ornamenting rubber surfaces with overlying rubber compositions of contrasting appearance. C. D. HOPKES. U. S. 1,560,472, Nov. 3. Different fluid rubber compns. are successfully applied and vulcanized together.

Variegated rubber. F. T. ROBERTS. U. S. 1,560,862, Nov. 10. Mech. features of uniting differently colored layers of rubber, exhausting the air from the united layers and then slicing to produce sheets with colored striations.

Treating rubber with carbon and absorbed gases. E. B. SPEAR. U. S. 1,560,488, Nov. 3. Rubber is mixed with a portion of unactivated C at least partially satd. with diethylamine or NH_3 and another portion of unactivated C containing CS_2 or CO_2 which will react to form a vulcanization accelerator.

Treating reclaimed rubber. H. HUNTER. U. S. 1,558,546, Oct. 27. A mass of small pieces of reclaimed rubber is exposed to the air, agitated and repeatedly dropped through the air to sep. them and expose them fully to the action of the air, while maintaining the relative humidity of the air between 15 and 75% and the temp. above 43°. This treatment serves to remove moisture from the rubber.

Retarding oxidation of rubber. S. M. CADWELL. U. S. 1,556,415, Oct. 6. Vulcanized rubber is treated with a reaction product of acetaldehyde and aniline or other material unable to activate O but adapted to absorb activated O. Numerous examples are given. Cf. C. A. 19, 750.

Treating latex. M. C. TRAGUE. U. S. 1,550,466, Aug. 18. Latex is thickened and stabilized by adding Na silicate or other easily decomposable colloidal silicate and an alkali, *e. g.*, NH_4OH .

Dyeing rubber. D. J. MEYERINGH and P. C. WIJNAND. U. S. 1,559,343, Oct. 27. Raw rubber in sheet form is treated with a soln. of coloring matter in a solvent such as C_6H_6 or CS_2 which is capable of penetrating throughout the rubber treated. The raw rubber is treated with S and vulcanized by the action of actinic rays.

Vulcanizing rubber. T. W. MILLER. U. S. 1,551,012, Aug. 25. Rubber contg. a metal oxide such as ZnO is subjected to the action of a soln. such as naphtha contg. CS_2 and a "class A" accelerator. S and an accelerator of "class B" are added as required.

Vulcanizing rubber. T. WHITTLESBY and C. E. BRADLEY. U. S. 1,559,393, Oct. 27. A substantially halide-free reaction product of a S halide and an amine, *e. g.*, the reaction product of aniline and S chloride, is used for vulcanizing.

Vulcanizing rubber. H. A. WINKELMANN and H. L. TRUMBULL. U. S. 1,559,925, Nov. 3. Rubber is mixed with ZnO and S or other vulcanizing agent and with an aldehyde-thiourea condensation product as an accelerator.

Vulcanizing rubber. C. M. CARSON. U. S. 1,560,465, Nov. 3. NH_3 and CH_2O , H_2S , CO_2 or other vulcanization accelerator components are introduced into rubber in a plurality of sep. portions by means of a carrying agent such as activated C to secure accurate control of vulcanization.

Vulcanizing rubber. S. B. MOLONY. U. S. 1,558,707, Oct. 27. Thiuram disulfide is used as an accelerator.

Vulcanizing rubber. G. H. STEVENS. U. S. 1,559,196, Oct. 27. Tetratolytri carbodiimide is used as an accelerator. U. S. 1,559,197 specifies tetraxylitricarbodiimide. U. S. 1,559,198 specifies tetraphenyltricarbodiimide.

Molds for vulcanizing. R. L. SHLEFY. U. S. 1,559,289, Oct. 27. Surfaces of molds are sprayed with a dil. aq. soln. of "Na sulfonate" (from petroleum acid sludge), which serves to prevent sticking of the rubber.

Adding rubber latex to facilitate milling of unvulcanized rubber. E. E. A. G. MEYER. U. S. 1,558,701, Oct. 27.

Composition for sealing punctures in tires. E. J. HOUDRY. U. S. 1,556,834, Oct. 13. A puncture-sealing mixt. is prepd. by boiling bran and soda soln., adding salicylic acid to the cooled material and also adding kieslguhr and asbestos.

Puncture-sealing composition. T. R. LAW. U. S. 1,561,332, Nov. 10. A mixt. for closing punctures in pneumatic tires comprises ground asbestos 16, pulverized slippery elm bark 1 and H_2O about 48 parts.

CHEMICAL ABSTRACTS

Vol. 20.

JANUARY 20, 1926

No. 2

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

The possibility of using chemists in the machinery and apparatus construction industries. FRICH GUNDERMANN. *Chem. App.* 12, 155-6, 191-2(1925).—A discussion of the advantages to be derived from the cooperation of chemists in these industries.

J. H. MOORE

Aluminium as a material in the apparatus-building industry. H. BUSCHLINGER. *Apparatebau* 37, 241-2, 253-4, 273-4, 285-6, 297-8(1925).—Comparative tables of the expansion coeffs. of Al and other metals, of the cond., expansion and phys. properties of Al and Cu and the resistance of Al to org. acids are given.

J. H. MOORE

A simple new apparatus for the determination of helium in mixtures of natural gases and in minerals. WITALIUS CHLOPIN AND A. LUKASUK. *Ber.* 58B, 2392-6 (1925).—About 200 cc. of the gas mixt., measured in a gas buret, are transferred to an evacuated system that includes a coconut charcoal tube cooled in liquid air and a Plücker tube. The unsorbed He, after being tested spectroscopically for impurities, is pumped into and measured in a small-bore gas buret graduated in 1/100 cc. The second transfer is conveniently accomplished by means of a modified McLeod gage. A small-bore gas buret replaces the usual gage capillary and can be shut off from the gage bulb by a stopcock. Manipulation of the Hg level and the stopcock pumps the He into the buret. Detn. of as little as 0.0005 vol. % of He in a 200 cc. gas sample is claimed. The method can also be used to det. He evolved from small samples of minerals.

R. L. DODGE

Apparatus for rectifying current in the investigation or determination of electric transport of colloids. G. REBIÈRE. *Chimie et industrie Special No.*, 390-1(Sept., 1925).—The app. is based on the property of thermionic valves (triple-electrode lamps) the hot filament of which emits electrons which allow current to pass between the filament and plate but only when the latter is at the higher potential. A single valve cuts off half the current and gives an intermittent current. By suitably mounting 4 such valves in the arms of a Wheatstone's bridge the current flowing in both directions can be utilized, the liquid investigated being connected across the bridge. With liquids contg. not more than a trace of electrolytes, voltages up to 1000 and more can be used.

A. PAPINEAU-COUTURE

Improved thickener filter for chemical operations. NOEL CUNNINGHAM. *Chem. Met. Eng.* 32, 750-2(1925); cf *C. A.* 19, 2427, 2468.—This app. consists of a thickener with a filter bottom, thus giving increased capacity and crystal clear filtrate.

L. A. P.

Tools of the chemical engineer. V. Filling and labeling small packages. D. H. KILLEFFER. *Ind. Eng. Chem.* 17, 1130-4(1925).—Automatic machinery for filling, closing, labeling and packing bottles, for pill making and for miscellaneous packaging operations, is described.

WM. B. PLUMMER

Precision X-ray spectrometer for chemical investigations. G. L. CLARK, H. C. WEBER AND R. L. HERSHEY. *Ind. Eng. Chem.* 17, 1147-50(1925).—A description of equipment installed in C.'s lab. at the Mass. Inst. of Technology, including details of technic recommended for similar installations.

G. L. CLARK

The Pierre Breuil volumometer. ANON. *Caoutchouc & gutta-percha* 22, 12915-6 (1925).—The app. is designed primarily for detg. the apparent d. of wood, but is applicable to general use, e. g., rubber. It consists of a vertical cylindrical chamber, near the bottom of which is a horizontal tube contg. a piston. The latter penetrates the vertical chamber and can be screwed back and forth. The tube carrying the piston is graduated micrometrically and a sleeve moving with the piston also has a micrometer scale, so that the motion of the piston can be very accurately detd. The vertical chamber can be opened and closed, the cover having a small tube with funnel. The chamber is filled with Hg and the piston micrometer read when the Hg reaches a mark on the funnel tube. The sample, e. g., 20 × 20 × 30 mm, or any irregular shape, is

introduced and the Hg again brought to the mark. The vols. corresponding to the micrometer readings being known, the vol. of the sample is detd. To avoid errors due to absorption of Hg, the sample is weighed, the first reading made with the sample in the app and finally a reading made after removal of the sample. C. C. DAVIS

Portable cutting and polishing machine with flexible cord drive. BERNHARD KLEINSCHMIDT. *Apparatebau* 37, 300-2(1925); 6 cuts. J. H. MOORE

A wash-bottle valve. H. C. STEPHENSON. *Chemistry & Industry* 44, 1112(1925).—A sliding valve in the portion of the mouth piece which passes through the stopper can be controlled by the thumb. E. H.

Steam measurement. M. SCHAAK. *Apparatebau* 37, 231-3, 245-6, 252-3, 276-8, 289(1925).—Descriptions with 13 cuts, of meters, gages and recorders, with mathematical discussion. J. H. MOORE

Flow meters in the accounting of process steam. CHAPLIN TYLER. *Chem. Met. Eng.* 32, 755-6(1925).—Steam flow meters in a soap plant pointed the way to substantial savings in steam costs. Tables are given showing cost and distribution of steam before and after installing steam meters. L. A. PRIDGEON

Optical pyrometer. F. E. BASH. U. S. 1,561,583, Nov. 17.

Thermometers. A. T. HESPE. U. S. 1,561,925-6, Nov. 17.

Metallic weighting and weight-adjusting band for attachment to the necks of testing bottles, flasks, etc. P. KIER. U. S. 1,561,984, Nov. 17.

Annular kiln for drying and carbonizing coal, ores, etc. O. DOBBELSTEIN and H. HESS. U. S. 1,556,571, Oct. 6.

Apparatus for drying wet coal or other materials by the action of hot gases. D. V. SHERBAN. U. S. 1,558,119, Oct. 20.

Rotary kiln for calcining, clinkering, etc. E. G. STONE. U. S. 1,550,591, Aug. 18.

Nonaerating apparatus for centrifugal purification of oil or other liquids. S. H. HALL. U. S. 1,561,784, Nov. 17.

Apparatus for "fatigue" tests of materials. A. AMSLER. Brit. 232,817, May 17, 1924.

Impact apparatus for fatigue tests of materials. A. AMSLER. Brit. 232,905, April 23, 1924.

Apparatus for concentrating saline solutions or other liquids. F. L. ANTISELL. U. S. 1,561,898, Nov. 17. Heat-conducting elements, which may be formed of ferro-Si, extend from a combustion chamber, through a partition, into an evap. chamber beneath the combustion chamber where they dip into the liquid to be evapd.

Apparatus for extracting oils, gelatin, etc., from animal or vegetable materials by grinding, steaming, etc. K. HOLTER and S. THUNE. Brit. 232,601, April 16, 1924.

Apparatus for drying "ceramic and chemical products." P. KIESS. Brit. 232,851, Sept. 11, 1924.

Grid for supporting purifying material in gas purifiers. J. A. SPENCER. Brit. 232,791, May 16, 1924. Structural features.

Evaporating apparatus for evaporating liquids in film form in tubes. GRISCOM-RUSSELL Co. and L. E. SEBALD. Brit. 232,925, April 25, 1924.

Electron-discharge device. J. R. WILSON. U. S. 1,562,403, Nov. 17. A cathode is supported by a Mo hook passing through a resilient helix of Monel metal. The hook carries a Ni sheave welded to the hook and to the helix.

Cathode for electric discharge tubes. H. SIMON. Can. 254,172, Sept. 20, 1925. A cathode contains an alk. earth metal and one or more of the rare metals.

Thermoelectric couple. R. P. BROWN. U. S. 1,561,593, Nov. 17. In a device comprising a primary couple and 2 extension elements, one of the extension elements is formed of an alloy contg. Cu 54, Ni 45 and Mn 0.25-1 part. This extension is attached to a primary element of Ni-Al alloy and the other extension (of pure Cu) is attached to a primary element of Ni-Cr alloy.

Retort furnace with rotary cylinders adapted for destructive distillations. O. D. LUCAS. U. S. 1,561,735, Nov. 17.

Tilting furnace for the fusion of basalt, etc. P. DIER. U. S. 1,558,250, Oct. 20.

X-ray apparatus. W. D. COOLIDGE. U. S. 1,550,506-7, Aug. 18.

Ultra-violet ray apparatus. R. G. PADDOCK. U. S. 1,559,770, Nov. 3. The app. is especially adapted for therapeutic purposes.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

The appeal of science to the community. ALEX. FINDLAY. *Science* **62**, 357-63 (1925).—An address. E. J. C.

Organization of chemists in the United States. CHAS. E. MUNROE. *Science* **62**, 313-7 (1925). E. J. C.

Chandler: the teacher and the chemist. M. I. PUPIN. *Science* **62**, 499-501 (1925). **Chandler and the Columbia School of Mines.** GEO. B. PIGRAM. *Ibid* 501-3. E. J. C.

Edward DeMille Campbell. A. H. WHITE. *Ind. Eng. Chem.* **17**, 1203 (1925).—An obituary, with portrait. E. J. C.

The pigments of the ancient Romans as described in the natural history of the elder Pliny. K. C. BAILEY. *Chemistry & Industry* **44**, 1135-7 (1925). E. H.

Dimensional system of notation. V. PETROVSKY. *Gen. Elec. Rev.* **28**, 757-61 (1925).—Mathematical difficulties may be eliminated by the use of a dimensional system of notation in which the phys. quantities are treated entirely algebraically. Empirical formulas presented in the numerical system must be accompanied by a list of "units" involved. By an algebraical transformation any empirical formula can be converted to a dimensional form requiring no additional explanations and independent of any system of units. Applications are illustrated in such cases as magnetic field intensity, power loss, sp. wt., and sp. vol. W. H. BOYNTON

The discovery of aluminium. KARL GOLDSCHMIDT. *Chimie et industrie* **14**, 368-70 (1925).—Controversial with Matignon and Faurholt (*C. A.* **19**, 1212). G. considers Al was discovered by Wöhler, not by Oersted. Also in *Z. angew. Chem.* **38**, 1057-8 (1925). C. MATIGNON. *Ibid* 370. —Reply to Goldschmidt. A. P. C.

Two new elements of the manganese group. I. Chemistry. W. NODDACK AND I. TACKE. *Sitzb. Preuss. Akad. Wissenschaften* **1925**, 400 5. II. **Röntgen spectroscopy.** O. BERG AND I. TACKE. *Ibid* 405-9. —The properties of elements 43 and 75 are computed from those of neighboring elements; their presence in Pt ores and columbite is indicated by chem. tests, and confirmed by the measurements of the $K\alpha_1$, $K\alpha_2$ and $K\beta_1$ lines in the X-ray emission spectra of element 43, and of the $L\alpha_1$, $L\alpha_2$, $L\beta_1$ and $L\beta_2$ lines of element 75. They are given the names and symbols: 43 masurium, Ma; 75 rhenium, Re. GEORGE CALINGAERT

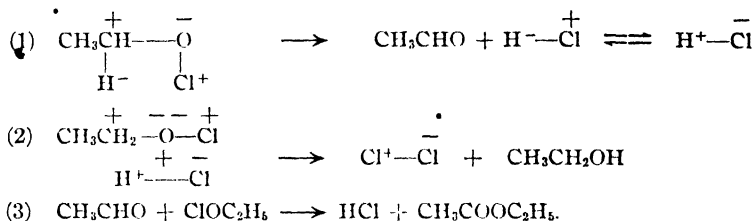

Two new elements, masurium and rhenium. R. SWINNE. *Z. tech. Physik* **6**, 464 5 (1925); cf. *Nature*, **115**, 954. —A short history of events leading up to the discovery of masurium (Ma) [43] and rhenium (Re) [75]. J. H. P.

Cryoscopic molecular weight determinations with liquid ammonia. I. SCHMIDT AND B. BECKER. *Ber* **58B**, 1968-71 (1925). —Measurements of the depression of the f. p. of anhyd. NH_3 by soln. of poly-saccharides will be useful in detg. the degree of polymerization or association in the polysaccharide mol. Before such information can be obtained it is necessary to det. the f. p. const. of anhyd. NH_3 . This const. was measured, with mannitol and acetanilide as solutes. The concn. range investigated was for mannitol 0.1266-0.2785 g. per 17.1 g. NH_3 , and for acetanilide 0.0438-0.2328 g. per 17.1 g. NH_3 . The app. employed was essentially a Beckmann app. with Pt resistance thermometer. The mean observed f. p. const. was 13.18. The mol. wt. of *inulin*, as detd. from cryoscopic measurements in anhyd. NH_3 over the concn. range 0.0333-0.2602 g. per 17.1 g. NH_3 , corresponded to the formula $\text{C}_{12}\text{H}_{20}\text{O}_{10}$. R. L. DODGE

A study of the physical properties of nitromethane. J. W. WILLIAMS. *J. Am. Chem. Soc.* **47**, 2644-52 (1925); cf. *C. A.* **18**, 1605, 2637. —In order to investigate the tautomeric equil. in nitromethane the following properties, in samples subjected to various drying treatments, were studied: (1) Sp. heat, (2) vapor pressure, (3) density and (4) absorption spectra. The variation of these properties with temp. was investigated at small intervals from 15° to 65° and in the sp. heat-temp. curves marked irregularities were noticed which were influenced in part by the previous drying treatments. This was taken as evidence of the presence of more than 1 species of mol. Empirical equations for the effect of temp. on the above properties are given. CH_3NO_2 contg. traces of H_2O gives a gel with P_2O_5 . The probability of an abnormal b. p. as a result of intensive drying is indicated. R. E. GIBSON

Hypochlorous esters and the question of the polarity of valences. J. F. DURAND AND R. NAVES. *Bull. soc. chim.* **37**, 1147-55 (1925); cf. *C. A.* **19**, 2807. — EtOCl decomposes spontaneously to give AcH , AcOEt , EtOH and free Cl_2 . The authors explain these reactions by applying the theory of the polarities of the atoms or groups in a

compd (cf. W. A. Noyes, *C. A.* **18**, 3497). They emphasize that such polar characteristics are purely relative and show that Cl_2 must be regarded as functioning as a positive atom in hypochlorous salts and esters. The polar formula, $\text{Et}-\overset{+}{\text{O}}-\overset{-}{\text{Cl}}$, is given to EtOCl and supported by its reactions with halogens and halogen acids. EtOCl is to be regarded as an ethylate of Cl rather than an ester of HOCl . The auto-compn. is formulated as follows:

R. E. GIBSON

Homopolarity of halides of the fourth group as indicated by the additive character of their melting points. A. HANTZSCH AND H. CARLSOHN. *Ber.* **58B**, 1741-6(1925).—Halides of the 4th group are characterized as homopolar because their m. and b. ps. are only slightly affected by association. For such cases the well-known rule holds abs. m. p./abs. b. p. = 0.62 (approx.). That this rule applies to the alkali metal halides was shown by R. Lorenz and W. Herz (cf. *C. A.* **15**, 3237). Tables showing the m. ps. and b. ps. of the halides of Si, Ge, Sn, Ti and Pb indicate that the rule applies to them. The const. varies regularly from 0.58 to 0.63 for the alkali halides, decreasing from Cl to I. For the 4th-group halides the const. increases regularly from 0.62 to 0.70. The m. ps. of the 4th-group halides can be calculated fairly accurately from the empirical formula: $(M_{m.p.} + nX_{m.p.})/(n + 1) = m.p. \text{ of the halide}$. $M_{m.p.}$ designates the m. p. of an element having a valence n and $X_{m.p.}$ designates the m. p. of the corresponding halogen. This leads to the conclusion that, on uniting with the halogens, the atoms are changed only slightly. This is a contradiction to Fajans' theory of deformation (K. Fajans and G. Joos, *C. A.* **18**, 2103), according to which these compds. should be built up with heteropolarity from highly deformed ions.

R. A. BAKER

Pseudo- and nonelectrolytes; their similarity to the noble gases as a basis for the calculation of their melting and boiling points. HEINRICH CARLSOHN. *Ber.* **58**, 1747-52(1925), cf. Paneth and Rabinowitsch, *C. A.* **19**, 2460.—A no. of curves are shown in which the m. p. and b. p. of A, Kr and Xe are plotted against the corresponding properties of inorg. halides and hydrides and aliphatic and aromatic halides, resp. On the basis of the relationships shown by these curves between the properties of noble gases and nonelectrolytes, C. proposes two laws: (1) The m. p. of non-associated pseudo- and nonelectrolytes are directly proportional to the m. ps. of their corresponding noble gases. (2) The b. ps. of nonassociated pseudo- and nonelectrolytes are directly proportional to the b. ps. of their corresponding noble gases. C. concludes that nonelectrolytes and pseudoelectrolytes like HCl do not consist of several ions; rather the whole mol. represents one structure which is similar to that of the noble gases. In nonelectrolytes the positive ion and not the valence electrons takes up the free electron spaces of the negative atoms. For example, the Sn of SnCl_4 does not give up 4 electrons to 4 Cl atoms, but the 4 electrons are shared by the Sn and Cl. By means of the 2 laws proposed it is possible to det. whether a compd. is homopolar and whether it is associated in the solid or liquid state.

R. A. BAKER

The structure of ammonia. H. MARK AND E. POHLAND. *Z. Krist.* **61**, 532-7(1925).— NH_3 is cubic between -77° and -160° . The unit cube contains 4 mols. and $a = 5.19 \text{ A. U.}$ The N atoms are arranged according to T^4 , with $u = 0.220$.

L. S. RAMSDELL

Structure of carborundum (SiC). H. OTT. *Z. Krist.* **61**, 515-31(1925); cf. *C. A.* **19**, 1212, 3393.—Carborundum (type II) can be considered as having a zinc blende structure twinned along a trigonal axis. The compd. is non-polar.

L. S. R.

Molecules, atoms and ions in crystal structure. W. HERZ. *Arch. Pharm.* **263**, 521-37(1925).—A discussion.

W. O. E.

The lattice structure of ethane and diborane (B_2H_6). H. MARK AND E. POHLAND. *Z. Krist.* **62**, 103-12(1925).—Both compds. crystallize in the hexagonal system with

very similar structures. The unit cell contains 4 mols. For ethane and diborane, resp., the dimensions in A. U. are $a = 4.46, 4.54, c = 8.19, 8.69$, and the vol. in (A. U.)³ occupied by the mols. are 70.6 and 78.0. The distance of nearest approach of atoms is C—C = 1.5—1.6, and B—B = 1.8—1.9 A. U. L. S. RAMSDELL

Structure investigations by the Debye-Scherrer (powder) method. S. V. OLSHAUSEN. *Z. Krist.* **61**, 463-514(1925).—Data are given for KI, RbCl, Al, Nb, Mn, red P, PbSe (clausthalite), HgS (cubic and hexagonal), As, Te, Se, (Ni, Fe) AsS (gersdorffite), and CaCO₃ (calcite, aragonite and vaterite). Vaterite, shown by Rime (*Z. Krist.* **60**, 66(1921)), to be distinct from calcite, is found to be hexagonal. A mathematical method for interpreting the diffraction patterns is described, and tables are given for use with this method. L. S. RAMSDELL

The arrangement of micro-crystals in aluminium wire. TAKEO FUJIWARA. *Mem. Coll. Sci. Kyoto Imp. Univ.* **8A**, 339-52(1925).—(In English.) Pinhole(transmission) photographs with Mo X-rays show that the *micro-crystals in drawn wires of Al and Cu* have trigonal axes approx. parallel to the direction of drawing, with a random orientation in other respects. Detailed examn. in the case of Al wire showed that crystals with trigonal axes inclined at an angle of 7° to the axis of the wire (direction of drawing) predominate. Wires were drawn about 50 times, from an initial diam. of 8 mm. to a final diam. of 1-0.6 mm. R. J. HAVIGHURST

The arrangement of the micro-crystals in rolled platinum plate. I. SHINSUKE TANAKA. *Mem. Coll. Sci. Kyoto Imp. Univ.* **8A**, 319-36(1925).—(In English.) Photographs of the Mo X-ray spectra reflected from the surface of rolled Pt foil and pin-hole (transmission) X-ray photographs show that the micro-crystals are arranged so that a (110) plane is parallel to the surface of rolling. The trigonal axis which is contained in the same (110) plane is perpendicular to the direction of rolling. There is slight deviation of the orientation from this ideal arrangement. Pt foil 0.5 mm. thick was heated almost to melting, then quenched, then rolled to a thickness of 0.03 mm. R. J. HAVIGHURST

The orientations of crystals in electrodeposited metals. R. M. BOZORTH. *Phys. Rev.* **26**, 390-400(1925).—Electrodeposited films of Cu, Zn and Cd were found by X-rays to have crystals oriented at random, but Fe, Ni and Co showed special orientations. The special orientation is thought to be associated with the strain developed during deposition because of H₂ liberated. A graphical method of interpreting X-ray fiber diagrams is given. D. C. BARDWELL

An application of X-ray crystallography to the structure of nickel catalysts. G. I. CLARK, W. C. ASBURY AND R. M. WICK. *J. Am. Chem. Soc.* **47**, 2661-7(1925).—Powder diffraction photographs in a new, inexpensive, but precise spectrograph have been taken of Ni catalysts of widely different hydrogenation and dehydrogenation activities, prepared by reduction with C, alc., AcOEt, H₂ and Na hypophosphite. Except for the last, which appeared colloidal, all give identical lines for Ni, $d_{100} = 3.536$ A. U. Hence the difference in activities is not to be ascribed to a difference in lattice type or dimensions. Precision photodensitometer curves from the films were prepared and used to measure relative intensities and widths of lines. The intensities for all were approx. the same and in fair agreement with the calcd. values for a face-centered lattice. The Ni catalysts do not obey the Debye-Scherrer equation connecting line width with particle size, defined for colloidal dimensions. A rough parallelism is found between decreasing line width and increasing catalytic activity. X-rays give no information concerning the surface of catalysts. Precision measurements on NiO (simple cubic) gave $d_{100} = 4.16$ A. U. Ni₂O₃ gave only the lines of the monoxide, proving it to be NiO.NiO₂. Photographs of the dioxide in its two forms gave no diffraction lines, explaining the nonappearance of these lines on the sesquioxide film. Ni₃O₄ was also amorphous. G. L. CLARK

The influence of the lanthanide contraction on the lattice dimensions of cubic metals of the platinum group. TOM. BARTH AND GULBRAND LUNDE. *Z. physik. chem.* **117**, 478-90(1925); cf. *C. A.* **19**, 2764.—"Lanthanide contraction" is the term applied to the volume contraction of the atoms in the rare earth series Ce-Cu. This contraction opposes the progressive increase of at. vol. in each vertical column of the periodic table, causing the pairs Ag-Au, Pd-Pt, Rh-Ir, and Mo-W to have very nearly equal lattice constns. Precision measurements by the powdered-crystal method of X-ray analysis were made to det. this effect quant. Films were calibrated by means of NaCl lines from salt which was mixed with each metal powder. The lengths of cube sides for Rh, Ir, Pd, Pt, resp. are: 3.795, 3.823, 3.873, 3.903 A. U. R. J. H.

Body-shaped (somatoid) crystal forms. V. KOHLSCHÜTTER AND C. EGG. *Helvetica Chim. Acta* **8**, 457-69(1925).—A review of previous work and a summary of

mixt. composed of terra japonica $1\frac{1}{2}$ and pulverized alum $\frac{1}{2}$ lb. and H_2O for several days, the hides being removed for airing at intervals.

Tanning composition. C. IMMERHEISER and H. WOLFF. U. S. 1,557,844, Oct. 20. By the treatment of crude $C_{14}H_{10}$ or "anthracene waste" with H_2SO_4 and adding Cl , $NaOCl$ or oxalic acid a sulfonated crude anthracene is obtained which slowly produces a pure brown coloration on hides suspended in its dil. acid soln. Formaldehyde also may be added.

Tanning composition. G. W. LANGLEY and A. A. HOWELL. U. S. 1,557,174, Oct. 13. A mixt. of ext. of wild cherry bark, ext. of sumac gum, gambier and H_2O .

Tanning substances. O. SPENGLER and A. THURM. U. S. 1,550,589, Aug. 18. Tanning compns. which are dark hygroscopic powders sol in H_2O are produced by heating alicyclic acid sulfochloride or other arylsulfochloride at $160-200^\circ$ with phenol or other hydroxyaryl compds without addition of condensing agents.

● **Glue globules.** A. OBERSOHN, W. WACHTEL, D. SAKOM and P. ASKENASY. U. S. 1,559,126, Oct. 27. A hot concd. glue soln. is sprayed under pressure to form drops which are cooled by passing through a cooling gas under pressure. Cf. C. A. 19, 1744.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Something about the drying and smoking of rubber. R. RIEBL. *Arch. Rubbercultuur* 9, 794-812(1925).—An address. F. H. YORSTON

Viscosity of rubber solutions. C. I. ABERNETHY. *India Rubber J.* 70, 775-83 (1925).—Various methods which have been developed for detg. the viscosity of liquids, particularly rubber solns., are described, with an extended discussion of the physics involved in the falling-sphere viscometer. By the aid of the latter an exptl. study was made of the viscosity of rubber solns. In these expts. the variation in viscosity of rubber solns. with variation in concn. and with change of temp. at different concns. was detd. for 10-30% solns. and temps. of $10-60^\circ$. The results are given in tables and graphs. At a given temp. the abs. viscosity increases with the concn. at a slowly increasing rate up to 15% rubber, after which the viscosity varies directly with the concn. At all concns. the abs. viscosity in $PhMe$ is less than that in C_6H_6 . The decrease in viscosity with increase in temp. is greatest in highly concd. solns., the temp. effect becoming less and less with increase in diln. Likewise for a given concn. the change in viscosity for a given change in temp. becomes less and less as the temp. increases. Further work to derive a relation between viscosity and concn., in which the applicability of the logarithmic formula of Arrhenius (cf. *Z. physik. Chem.* 1887, I, 285) as well as more recent ones was tested, shows that none of these log. formulas is applicable to rubber solns. But by plotting the sq. roots of the concns. against the logs. of the viscosities, straight lines are obtained, the relation $\eta_c = K e^{k\sqrt{c}}$ being derived, where η_c is the viscosity in C. G. S. units of a soln. contg. c g. of rubber in 100 cc. of soln., K and k are consts. and e is the base of the Napierian logs. Calcn. from the graphs shows K to be $e^{-6.102}$ for all temp. and k to be 2.413 at 10° and 2.176 at 60° . Extrapolation in turn shows the viscosity of milled rubber itself to be 22,400,000 and 2,290,000 C. G. S. units at 10° and 60° , resp. This ten-fold decrease in viscosity between 10° and 60° emphasizes the importance of accurate temp. control in any method for detg. the relative viscosity of rubber. Below 1% concn. Arrhenius' equation is valid, perhaps for the reason advanced by Hatschek for 2-phase emulsoid systems in general (cf. C. A. 7, 3873). Application of the method to solns. of raw unmilled rubber at 15.5° showed the following viscosity in C. G. S. units: 2%, 5.04; 3%, 35.63; 4%, 162.8; 5%, 464.4; 6%, 1577. In this case also, the new equation $\eta_c = K e^{k\sqrt{c}}$ was valid. Application of the latter to other published work, e. g., Me_2CO solns. of nitrocellulose (cf. C. A. 14, 3153) shows the validity of the new equation with solns. other than those of rubber. C. C. D.

Plasticity determination in crude rubber. IV. Difference between smoked sheet and pale crepe. O. DE VRIES. *Arch. Rubbercultuur* 9, 813-36(1925); (In *English Ind* 837-43).—The av. d_{30} and H (cf. C. A. 19, 2281-2) for 13 crepes prepd. on a small mill were 1.395 and 0.070, resp. and for corresponding air-dried sheets 1.595 and 0.083. Accordingly crepe was the more plastic rubber. There was a smaller difference of about 0.1 between the d_{30} of crepes and of sheets prepd. on an estate by R. Riebl. A distinct plasticizing effect was noted on long maceration of the rubber. Great diln. of the latex before coagulation also gave a definite decrease in d_{30} . No marked change in plasticity could be ascribed to rolling into sheets (compared with air-drying of fresh

or matured coagulum without mechanical treatment), to the use of H_2O on the rolls, to soaking freshly rolled sheets in H_2O , to heating the wet rubber or to smoking. These conclusions refer to rubber tested within a month of its prepn. under which conditions there was no important difference between fresh crepe and sheet. An earlier statement that crepe was the harder rubber was based on an examn. of a no. of samples some of which had hardened on keeping. The change in the plasticity of stored rubber is being studied.

F. H. YORSTON

A simple control test for the distribution of sulfide-containing ingredients in rubber goods. ANON. *Gummi-Ztg.* 40, 277(1925).—A preliminary communication. Sulfides decomposable by acids in rubber goods can be detected very easily by the appearance of colored spots when the rubber is treated with an acid and the H_2S acts on $AgBr$ or $HgCl_2$. As a simple technic, a smooth fresh surface of rubber is pressed for 3-5 min. against $AgBr$ paper which has been unattacked by light and which has just been steeped in 30% H_2SO_4 . The paper is then immersed in an acid-fixing bath, washed and dried. A fresh surface of rubber is necessary, since with old rubber oxidation of the original surface obscures the test. The method shows the uniformity and the degree of dispersion of the ingredients. Reproductions of rubber samples contg. lithopone are given.

C. C. DAVIS

Aging tests on rubber coagulated with acetic acid and *p*-nitrophenol. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 496-8, 565-7(1925); cf. *C. A.* 19, 3616.—In using $p-O_2NC_6H_4OH$ as a mold preventive it is now found best to dissolve an amt. equal to 0.03% of the latex in the $HOAc$ used for coagulation. Samples of sheet prepd. with this soln. cured, in a rubber-S mixt., about 10% faster than did the controls. A specimen which was vulcanized for 3 hrs. and was over-cured deteriorated greatly after 3 days aging at 70°, while the control reached the same stage in 4 days. A specimen cured 2 hrs. was at first somewhat stronger, but after aging for 6 days was somewhat weaker, than the control. Samples vulcanized for 105 and 120 min. reached the state of cure of controls vulcanized for 120 and 135 min., resp., and they deteriorated at practically the same rate as did the controls during aging for 210 hrs. The difference in rate of cure of $p-O_2NC_6H_4OH$ -prepd. rubber and ordinary rubber was greater in a mixt. contg. ZnO but no added org. accelerator, probably because of the destruction of part of the fatty acids in ordinary rubber by molds.

F. H. YORSTON

Smoked sheet rubber coagulated with acetic and formic acids containing *p*-nitrophenol. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 612-3(1925); cf. preceding abstr.—Satisfactory vulcanizates were prepd. from samples which had been coagulated with 1% solus. of $HOAc$ and of H_2CO_2 contg. $p-O_2NC_6H_4OH$.

F. H. YORSTON

Report on further experiments on the spotting of crepe rubber. W. BROWN. *Bull. Rubber Growers' Assoc.* 7, 522-32(1925), cf. *C. A.* 19, 2144.—Since fungi invade dry rubber only slowly, their behavior was more conveniently studied on strips which had absorbed about 25% H_2O by soaking at 47°. A *Penicillium* which had been isolated from crepe produced spotting on this rubber without the addn. of any nutrient. Very rapid spotting took place when the rubber was inoculated with a *Fusarium* in the presence of traces of NH_4 salts. The last of many washings from a piece of crepe contained enough nutrient to stimulate distinctly the germination of spores. Extn. of rubber with cold acetone removed much nutrient, since it reduced spotting to an extent for which the lessened swelling of the rubber in H_2O could not account. Spotting was most rapid at 30° and was very slow at 35°. Neither fungus germinated at 38°, and the spores of the *Fusarium* were killed by exposure to this temp. for 4 days. An increase of 5° in the temp. of the drying sheds should prevent spotting, both by retarding germination and by increasing the rate of drying. A concn. of 0.01% $p-O_2NC_6H_4OH$ in neutral or faintly acid soln. prevented the germination of both fungi.

F. H. YORSTON

Determination of balata in balata-rubber mixtures. J. T. CHARLTON. *India Rubber World* 72, 470(1925).—Correction (cf. *C. A.* 19, 1967). For "cool to 12°," read "cool to -12°."

C. C. DAVIS

Vulcanization. III. The cure. G. BERNSTEIN. *Rev. gén. caoutchouc* 1925, No. 15, 13-4; cf. *C. A.* 19, 3387.—A brief general description of the physics and chemistry of the vulcanizing process.

C. C. DAVIS

Latex. Insecticide preparation for combating plant parasites (DITMAR) 15. Manufacture of balloon fabrics (Dambroise) 25. Recovery of volatile solvents (LUTINGER) 13. Cement containing resin and rubber (U. S. pat. 1,561,095) 18.

Rubber composition. G. W. ACHESON. U. S. 1,560,132, Nov. 3. A solid inorg. substance such as china clay is deflocculated and the dry deflocculated material is

mixed with a rubber soln. and pptn. of the rubber is then effected by use of acetone or equiv. organic liquid. The rubber mixt. thus formed, after sepn. from associated liquid, is adapted for working or further blending, etc.

Rubber composition. L. E. KLUG. U. S. 1,550,968, Aug. 25. A compn. adapted for making mats, jars, etc., is prepd. by mixing scrap and reclaimed rubber with S, and adding "uncured friction"

"Compounding" rubber. C. C. LOOMIS and H. E. STUMP. U. S. 1,558,688, Oct. 27.* Particles or ingredients such as clay, S, ZnO or lampblack which are subsequently to be mixed with rubber are preliminarily given a thin coating of rubber, e. g., by treatment with ammoniacal latex and then with $Al_2(SO_4)_3$.

Ornamenting rubber surfaces with overlying rubber compositions of contrasting appearance. C. D. HOPKES. U. S. 1,560,472, Nov. 3. Different fluid rubber compns. are successfully applied and vulcanized together.

• **Variegated rubber.** F. T. ROBERTS. U. S. 1,560,862, Nov. 10. Mech. features of uniting differently colored layers of rubber, exhausting the air from the united layers and then slicing to produce sheets with colored striations

Treating rubber with carbon and absorbed gases. E. B. SPEAR. U. S. 1,560,488, Nov. 3. Rubber is mixed with a portion of unactivated C at least partially satd. with diethylamine or NH_3 and another portion of unactivated C containing CS_2 or CO_2 which will react to form a vulcanization accelerator.

Treating reclaimed rubber. H. HUNTER. U. S. 1,558,516, Oct. 27. A mass of small pieces of reclaimed rubber is exposed to the air, agitated and repeatedly dropped through the air to sep. them and expose them fully to the action of the air, while maintaining the relative humidity of the air between 15 and 75% and the temp. above 43° . This treatment serves to remove moisture from the rubber.

Retarding oxidation of rubber. S. M. CADWELL. U. S. 1,556,415, Oct. 6. Vulcanized rubber is treated with a reaction product of acetaldehyde and aniline or other material unable to activate O but adapted to absorb activated O. Numerous examples are given. Cf. C. A. 19, 750

Treating latex. M. C. TEAGUE. U. S. 1,550,466, Aug. 18. Latex is thickened and stabilized by adding Na silicate or other easily decomposable colloidal silicate and an alkali, e. g., NH_4OH .

Dyeing rubber. D. J. MEYERINGH and P. C. WIJNAND. U. S. 1,559,343, Oct. 27. Raw rubber in sheet form is treated with a soln. of coloring matter in a solvent such as C_6H_6 or CS_2 which is capable of penetrating throughout the rubber treated. The raw rubber is treated with S and vulcanized by the action of actinic rays.

Vulcanizing rubber. T. W. MILLER. U. S. 1,551,042, Aug. 25. Rubber contg. a metal oxide such as ZnO is subjected to the action of a soln. such as naphtha contg. CS_2 and a "class A" accelerator. S and an accelerator of "class B" are added as required.

Vulcanizing rubber. T. WHITTELEY and C. E. BRADLEY. U. S. 1,559,393, Oct. 27. A substantially halide free reaction product of a S halide and an amine, e. g., the reaction product of aniline and S chloride, is used for vulcanizing.

Vulcanizing rubber. H. A. WINKELMANN and H. L. TRUMBULL. U. S. 1,559,925, Nov. 3. Rubber is mixed with ZnO and S or other vulcanizing agent and with an aldehyde-thiourea condensation product as an accelerator.

Vulcanizing rubber. C. M. CARSON. U. S. 1,560,465, Nov. 3. NH_3 and CH_2O , H_2S , CO_2 or other vulcanization accelerator components are introduced into rubber in a plurality of sep. portions by means of a carrying agent such as activated C to secure accurate control of vulcanization.

Vulcanizing rubber. S. B. MOLONY. U. S. 1,558,707, Oct. 27. Thiuram disulfide is used as an accelerator.

Vulcanizing rubber. G. H. STIEVENS. U. S. 1,559,196, Oct. 27. Tetratolyltricarbondiimide is used as an accelerator. U. S. 1,559,197 specifies tetraxyliltricarbodiimide. U. S. 1,559,198 specifies tetraphenyltricarbodiimide.

Molds for vulcanizing. R. L. SIBLEY. U. S. 1,559,289, Oct. 27. Surfaces of molds are sprayed with a dil. aq. soln. of "Na sulfonate" (from petroleum acid sludge) which serves to prevent sticking of the rubber.

Adding rubber latex to facilitate milling of unvulcanized rubber. E. E. A. G. MEYER. U. S. 1,558,701, Oct. 27.

Composition for sealing punctures in tires. E. J. HOUDRY. U. S. 1,556,834, Oct. 13. A puncture-sealing mixt. is prepd. by boiling bran and soda soln., adding salicylic acid to the cooled material and also adding kieselguhr and asbestos.

Puncture-sealing composition. T. E. LAW. U. S. 1,561,332, Nov. 10. A mixt. for closing punctures in pneumatic tires comprises ground asbestos 16, pulverized slippery elm bark 1 and H_2O about 48 parts.

CHEMICAL ABSTRACTS

Vol. 20.

JANUARY 20, 1926

No. 2

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

The possibility of using chemists in the machinery and apparatus construction industries. ERICH GUNDERMANN. *Chem. App.* 12, 155-6, 191-2(1925).—A discussion of the advantages to be derived from the coöperation of chemists in these industries.

J. H. MOORE

Aluminium as a material in the apparatus-building industry. H. BUSCHLINGER. *Apparatebau* 37, 241-2, 253-4, 273-4, 285-6, 297-8(1925).—Comparative tables of the expansion coeffs. of Al and other metals, of the cond., expansion and phys. properties of Al and Cu and the resistance of Al to org. acids are given.

J. H. MOORE

A simple new apparatus for the determination of helium in mixtures of natural gases and in minerals. WITALIUS CHLOPIN AND A. LUKASUK. *Ber.* 58B, 2392-6 (1925).—About 200 cc. of the gas mixt., measured in a gas buret, are transferred to an evacuated system that includes a coconut charcoal tube cooled in liquid air and a Plücker tube. The unsorbed He, after being tested spectroscopically for impurities, is pumped into and measured in a small-bore gas buret graduated in 1/100 cc. The second transfer is conveniently accomplished by means of a modified McLeod gage. A small-bore gas buret replaces the usual gage capillary and can be shut off from the gage bulb by a stopcock. Manipulation of the Hg level and the stopcock pumps the He into the buret. Detn. of as little as 0.0005 vol. % of He in a 200 cc. gas sample is claimed. The method can also be used to det. He evolved from small samples of minerals.

R. L. DODGE

Apparatus for rectifying current in the investigation or determination of electric transport of colloids. G. REBIÈRE. *Chimie et industrie Special No.*, 390-1(Sept., 1925).—The app. is based on the property of thermionic valves (triple-electrode lamps) the hot filament of which emits electrons which allow current to pass between the filament and plate but only when the latter is at the higher potential. A single valve cuts off half the current and gives an intermittent current. By suitably mounting 4 such valves in the arms of a Wheatstone's bridge the current flowing in both directions can be utilized, the liquid investigated being connected across the bridge. With liquids contg. not more than a trace of electrolytes, voltages up to 1000 and more can be used.

A. PAPINEAU-COUTURE

Improved thickener filter for chemical operations. NOEL CUNNINGHAM. *Chem. Met. Eng.* 32, 750-2(1925); cf. *C. A.* 19, 2427, 2468.—This app. consists of a thickener with a filter bottom, thus giving increased capacity and crystal clear filtrate.

L. A. P.

Tools of the chemical engineer. V. Filling and labeling small packages. D. H. KILLEFFER. *Ind. Eng. Chem.* 17, 1130-4(1925).—Automatic machinery for filling, closing, labeling and packing bottles, for pill making and for miscellaneous packaging operations, is described.

WM. B. PLUMMER

Precision X-ray spectrometer for chemical investigations. G. L. CLARK, H. C. WEBER AND R. L. HERSHEY. *Ind. Eng. Chem.* 17, 1147-50(1925).—A description of equipment installed in C.'s lab. at the Mass. Inst. of Technology, including details of technic recommended for similar installations.

G. L. CLARK

The Pierre Breuil volumometer. ANON. *Caoutchouc & gutta-percha* 22, 12915-6 (1925).—The app. is designed primarily for detg. the apparent d. of wood, but is applicable to general use, e. g., rubber. It consists of a vertical cylindrical chamber, near the bottom of which is a horizontal tube contg. a piston. The latter penetrates the vertical chamber and can be screwed back and forth. The tube carrying the piston is graduated micrometrically and a sleeve moving with the piston also has a micrometer scale, so that the motion of the piston can be very accurately detd. The vertical chamber can be opened and closed, the cover having a small tube with funnel. The chamber is filled with Hg and the piston micrometer read when the Hg reaches a mark on the funnel tube. The sample, e. g., 20 × 20 × 30 mm, or any irregular shape, is

introduced and the Hg again brought to the mark. The vols. corresponding to the micrometer readings being known, the vol. of the sample is detd. To avoid errors due to absorption of Hg, the sample is weighed, the first reading made with the sample in the app and finally a reading made after removal of the sample. C. C. DAVIS

Portable cutting and polishing machine with flexible cord drive. BERNHARD KLEINSCHMIDT. *Apparaturbau* 37, 300-2(1925); 6 cuts. J. H. MOORE

A wash-bottle valve. H. C. STEPHENSON. *Chemistry & Industry* 44, 1112(1925).—A sliding valve in the portion of the mouth piece which passes through the stopper can be controlled by the thumb. E. H.

Steam measurement. M. SCHAAK. *Apparaturbau* 37, 231-3, 245-6, 252-3, 276-8, 289(1925).—Descriptions with 13 cuts, of meters, gages and recorders, with mathematical discussion. J. H. MOORE

• **Flow meters in the accounting of process steam.** CHAPLIN TYLER. *Chem. Met. Eng.* 32, 755-6(1925).—Steam flow meters in a soap plant pointed the way to substantial savings in steam costs. Tables are given showing cost and distribution of steam before and after installing steam meters. L. A. PRIDGEON

Optical pyrometer. F. E. BASH. U. S. 1,561,583, Nov. 17.

Thermometers. A. T. HESPE. U. S. 1,561,925-6, Nov. 17.

Metallic weighting and weight-adjusting band for attachment to the necks of testing bottles, flasks, etc. P. KIER. U. S. 1,561,984, Nov. 17.

Annuular kiln for drying and carbonizing coal, ores, etc. O. DOBBELSTEIN and H. HESS. U. S. 1,550,571, Oct. 6.

Apparatus for drying wet coal or other materials by the action of hot gases. D. V. SHERBAN. U. S. 1,558,119, Oct. 20.

Rotary kiln for calcining, clinkering, etc. E. G. STONE. U. S. 1,550,591, Aug. 18.

Nonaerating apparatus for centrifugal purification of oil or other liquids. S. H. HALL. U. S. 1,561,784, Nov. 17.

Apparatus for "fatigue" tests of materials. A. AMSLER. Brit. 232,817, May 17, 1924.

Impact apparatus for fatigue tests of materials. A. AMSLER. Brit. 232,905, April 23, 1924.

Apparatus for concentrating saline solutions or other liquids. F. L. ANTISELL. U. S. 1,561,898, Nov. 17. Heat-conducting elements, which may be formed of ferro-Si, extend from a combustion chamber, through a partition, into an evap. chamber beneath the combustion chamber where they dip into the liquid to be evapd.

Apparatus for extracting oils, gelatin, etc., from animal or vegetable materials by grinding, steaming, etc. K. HOLTER and S. THUNE. Brit. 232,601, April 16, 1924.

Apparatus for drying "ceramic and chemical products." P. KIESS. Brit. 232,851, Sept. 11, 1924.

Grid for supporting purifying material in gas purifiers. J. A. SPENCER. Brit. 232,791, May 16, 1924. Structural features.

Evaporating apparatus for evaporating liquids in film form in tubes. GRISCOM RUSSELL Co. and L. E. SEBALD. Brit. 232,925, April 25, 1924.

Electron-discharge device. J. R. WILSON. U. S. 1,562,403, Nov. 17. A cathode is supported by a Mo hook passing through a resilient helix of Monel metal. The hook carries a Ni sleeve welded to the hook and to the helix.

Cathode for electric discharge tubes. H. SIMON. Can. 254,172, Sept. 29, 1925. A cathode contains an alk. earth metal and one or more of the rare metals.

Thermoelectric couple. R. P. BROWN. U. S. 1,561,593, Nov. 17. In a device comprising a primary couple and 2 extension elements, one of the extension elements is formed of an alloy contg. Cu 54, Ni 45 and Mn 0.25-1 part. This extension is attached to a primary element of Ni-Al alloy and the other extension (of pure Cu) is attached to a primary element of Ni-Cr alloy.

Retort furnace with rotary cylinders adapted for destructive distillations. O. D. LUCAS. U. S. 1,561,735, Nov. 17.

Tilting furnace for the fusion of basalt, etc. P. DHE. U. S. 1,558,250, Oct. 20

X-ray apparatus. W. D. COOLIDGE. U. S. 1,550,506-7, Aug. 18.

Ultra-violet ray apparatus. R. G. PADDOCK. U. S. 1,559,770, Nov. 3. The app is especially adapted for therapeutic purposes.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

- The appeal of science to the community.** ALEX. FINDLAY. *Science* **62**, 357–63 (1925).—An address. E. J. C.
- Organization of chemists in the United States.** CHAS. F. MUNROE. *Science* **62**, 313–7 (1925). E. J. C.
- Chandler: the teacher and the chemist.** M. I. PUPIN. *Science* **62**, 499–501 (1925). **Chandler and the Columbia School of Mines.** GEO. B. PEGRAM. *Ibid* 501–3. E. J. C.
- Edward DeMille Campbell.** A. H. WHITE. *Ind. Eng. Che* **17**, 1203 (1925).—An obituary, with portrait. E. J. C.
- The pigments of the ancient Romans as described in the natural history of the elder Pliny.** K. C. BAILEY. *Chemistry & Industry* **44**, 1135–7 (1925). E. H.
- Dimensional system of notation.** V. PETROVSKY. *Gen. Elec. Rev* **28**, 757–61 (1925).—Mathematical difficulties may be eliminated by the use of a dimensional system of notation in which the phys. quantities are treated entirely algebraically. Empirical formulas presented in the numerical system must be accompanied by a list of "units" involved. By an algebraical transformation any empirical formula can be converted to a dimensional form requiring no additional explanations and independent of any system of units. Applications are illustrated in such cases as magnetic field intensity, power loss, sp. wt., and sp. vol. W. H. BOYNTON
- The discovery of aluminium.** KARL GOLDSCHMIDT. *Chimie et industrie* **14**, 368–70 (1925).—Controversial with Matignon and Faurholt (*C. A.* **19**, 1212). G considers Al was discovered by Wöhler, not by Oersted. Also in *Z. angew. Chem* **38**, 1057–8 (1925). C. MATIGNON. *Ibid* 370.—Reply to Goldschmidt. A. P. C.
- Two new elements of the manganese group.** I. Chemistry. W. NODDACK AND I. TACKE. *Sitzb. Preuss. Akad. Wissenschaften* **1925**, 400–5. II. **Röntgen spectroscopy.** O. BERG AND I. TACKE. *Ibid* 405–9.—The properties of elements 43 and 75 are computed from those of neighboring elements; their presence in Pt ores and columbite is indicated by chem. tests, and confirmed by the measurements of the $K\alpha_1$, $K\alpha_2$ and $K\beta_1$ lines in the X-ray emission spectra of element 43, and of the $L\alpha_1$, $L\alpha_2$, $L\beta_1$ and $L\beta_2$ lines of element 75. They are given the names and symbols 43 masurium, Ma, 75 rehenium, Re. GEORGE CALINGAERT
- Two new elements, masurium and rehenium.** R. SWINNE. *Z. tech. Physik* **6**, 464–5 (1925); cf. *Nature*, **115**, 954.—A short history of events leading up to the discovery of masurium (Ma) [43] and rehenium (Re) [75]. J. H. P.
- Cryoscopic molecular weight determinations with liquid ammonia.** I. SCHMID AND B. BECKER. *Ber* **58B**, 1908–71 (1925).—Measurements of the depression of the f. p. of anhyd. NH_3 by soln. of polysaccharides will be useful in detg. the degree of polymerization or association in the polysaccharide mol. Before such information can be obtained it is necessary to det. the f. p. const. of anhyd. NH_3 . This const. was measured, with mannitol and acetanilide as solutes. The concn. range investigated was for mannitol 0.1266–0.2785 g. per 17.1 g. NH_3 , and for ace. anilide 0.0438–0.2328 g. per 17.1 g. NH_3 . The app. employed was essentially a Beckmann app. with Pt resistance thermometer. The mean observed f. p. const. was 13.18. The mol. wt. of inulin, as detd. from cryoscopic measurements in anhyd. NH_3 over the concn. range 0.0333–0.2602 g. per 17.1 g. NH_3 , corresponded to the formula $\text{C}_{52}\text{H}_{106}\text{O}_{54}$. R. L. DODGE
- A study of the physical properties of nitromethane.** J. W. WILLIAMS. *J. Am. Chem. Soc.* **47**, 2644–52 (1925); cf. *C. A.* **18**, 1605, 2637.—In order to investigate the tautomeric equil. in nitromethane the following properties, in samples subjected to various drying treatments, were studied: (1) Sp. heat, (2) vapor pressure, (3) density and (4) absorption spectra. The variation of these properties with temp. was investigated at small intervals from 15° to 65° and in the sp. heat-temp. curves marked irregularities were noticed which were influenced in part by the previous drying treatments. This was taken as evidence of the presence of more than 1 species of mol. Empirical equations for the effect of temp. on the above properties are given. CH_3NO_2 contg. traces of H_2O gives a gel with P_2O_5 . The probability of an abnormal b. p. as result of intensive drying is indicated. R. E. GIBSON
- Hypochlorous esters and the question of the polarity of valences.** J. F. DURAND and R. NAVES. *Bull. soc. chim.* **37**, 1147–55 (1925); cf. *C. A.* **19**, 2807.—EtOCl decomposes spontaneously to give AcH, AcOEt, EtOH and free Cl_2 . The authors explain these reactions by applying the theory of the polarities of the atoms or groups in a

very similar structures. The unit cell contains 4 mols. For ethane and diborane, resp., the dimensions in A. U. are $a = 4.46, 4.54, c = 8.19, 8.69$, and the volume (A. U.)³ occupied by the mols. are 70.6 and 78.0. The distance of nearest approach of atoms is $C-C = 1.5 - 1.6$, and $B-B = 1.8 - 1.9$ A. U. L. S. RAMSDELL

Structure investigations by the Debye-Scherrer (powder) method. S. V. OLSHAUSEN. *Z. Krist.* **61**, 463-514(1925).—Data are given for KI, RbCl, Al, Nb, Mn, red P, PbSe (clausthalite), HgS (cubic and hexagonal), As, Te, Se, (Ni, Fe) AsS (gersdorffite), and $CaCO_3$ (calcite, aragonite and vaterite). Vaterite, shown by Rimsie (Z. Krist. **60**, 66(1921)), to be distinct from calcite, is found to be hexagonal. A mathematical method for interpreting the diffraction patterns is described, and tables are given for use with this method. L. S. RAMSDELL

The arrangement of micro-crystals in aluminium wire. TAKEO FUJIWARA. *Mem. Coll. Sci. Kyoto Imp. Univ.* **8A**, 339-52(1925).—(In English.) Pinhole(transmission) photographs with Mo X-rays show that the micro-crystals in drawn wires of Al and Cu have trigonal axes approx. parallel to the direction of drawing, with a random orientation in other respects. Detailed examn. in the case of Al wire showed that crystals with trigonal axes inclined at an angle of 7° to the axis of the wire (direction of drawing) predominate. Wires were drawn about 50 times, from an initial diam. of 8 mm. to a final diam. of 1.06 mm. R. J. HAVIGHURST

The arrangement of the micro-crystals in rolled platinum plate. I. SHINSUKE TANAKA. *Mem. Coll. Sci. Kyoto Imp. Univ.* **8A**, 319-36(1925).—(In English.) Photographs of the Mo X-ray spectra reflected from the surface of rolled Pt foil and pinhole (transmission) X-ray photographs show that the micro-crystals are arranged so that a (110) plane is parallel to the surface of rolling. The trigonal axis which is contained in the same (110) plane is perpendicular to the direction of rolling. There is slight deviation of the orientation from this ideal arrangement. Pt foil 0.5 mm. thick was heated almost to melting, then quenched, then rolled to a thickness of 0.03 mm. R. J. HAVIGHURST

The orientations of crystals in electrodeposited metals. R. M. BOZORTH. *Phys. Rev.* **26**, 390-400(1925).—Electrodeposited films of Cu, Zn and Cd were found by X-rays to have crystals oriented at random, but Fe, Ni and Co showed special orientations. The special orientation is thought to be associated with the strain developed during deposition because of H_2 liberated. A graphical method of interpreting X-ray fiber diagrams is given. D. C. BARDWELL

An application of X-ray crystallography to the structure of nickel catalysts. G. L. CLARK, W. C. ASHURY AND R. M. WICK. *J. Am. Chem. Soc.* **47**, 2661-7(1925).—Powder diffraction photographs in a new, inexpensive, but precise spectrograph have been taken of Ni catalysts of widely different hydrogenation and dehydrogenation activities, prepared by reduction with C, alc., AcOEt, H_2 and Na hypophosphite. Except for the last, which appeared colloidal, all give identical lines for Ni, $d_{100} = 3.536$ A. U. Hence the difference in activities is not to be ascribed to a difference in lattice type or dimensions. Precision photodensitometer curves from the films were prepared and used to measure relative intensities and widths of lines. The intensities for all were approx. the same and in fair agreement with the calcd. values for a face-centered lattice. The Ni catalysts do not obey the Debye-Scherrer equation connecting line width with particle size, defined for colloidal dimensions. A rough parallelism is found between decreasing line width and increasing catalytic activity. X-rays give no information concerning the surface of catalysts. Precision measurements on NiO (simple cubic) gave $d_{100} = 4.16$ A. U. Ni_2O_3 gave only the lines of the monoxide, proving it to be NiO NiO_2 . Photographs of the dioxide in its two forms gave no diffraction lines, explaining the nonappearance of these lines on the sesquioxide film. Ni_3O_4 was also amorphous. G. L. CLARK

The influence of the lanthanide contraction on the lattice dimensions of cubic metals of the platinum group. TOM. BARTH AND GULBRAND LUNDE. *Z. physik. Chem.* **117**, 478-90(1925); cf. *C. A.* **19**, 2764.—"Lanthanide contraction" is the term applied to the volume contraction of the atoms in the rare earth series Ce-Cu. This contraction opposes the progressive increase of at. vol. in each vertical column of the periodic table, causing the pairs Ag-Au, Pd-Pt, Rh-Ir, and Mo-W to have very nearly equal lattice constns. Precision measurements by the powdered-crystal method of X-ray analysis were made to det. this effect quant. Films were calibrated by means of NaCl lines from salt which was mixed with each metal powder. The lengths of cube sides for Rh, Ir, Pd, Pt, resp., are: 3.795, 3.823, 3.873, 3.903 A. U. R. J. H.

Body-shaped (somatoid) crystal forms. V. KOHLSCHÜTTER AND C. EGG. *Helvetica Chim. Acta* **8**, 457-69(1925).—A review of previous work and a summary of

papers to be published on the external shape of some ppts. K. and E. divide the "somatoid forms" in 3 groups: disk-shaped (scheiben), produced when the presence of a colloid in the soln. holds the precipitate in gelatinous form; (2) *a*-forms, in which the lattice forces are hindered to a greater or lesser degree by slow diffusion and mechanical action; (3) *b*-forms, same as *a*-forms, except that the influence of the lattice forces is outweighed by that of the accompanying colloids and by the aggregation processes.

GEORGE CALINGAERT

• **Modification of the habit and change in the crystal shape of calcium carbonate due to substances present in the solutions.** V. KOHLSCHÜTTER AND C. EGG. *Helvetica Chim. Acta* **8**, 470-90(1925).— CaCO_3 pptd. from bicarbonate solns. by air blowing crystallizes as calcite below 30° and as aragonite above. The presence of KCl and NaCl (in contradistinction to K_2SO_4) gives bigger but fewer crystals. Bivalent metal ions have a stronger effect. The appearance of aragonite below 30° , in the presence of Mg or Sr salts, was never observed, but the presence of these salts in great amts. modifies the shape of calcite crystals and gives "somatoid forms" (cf. preceding abstract), which previous authors may have described as aragonite. Salts of bivalent metals (Cu, Ni, Co, Zn) cause the appearance of hydrated CaCO_3 crystals of which are more stable when occluding traces of these compounds. The formation of somatoid forms may be considered as a highly hindered crystn.

G. CALINGAERT

A method for the determination of the orientation of crystallites in conglomerates. G. TAMMANN. *Z. anorg. allgem. Chem.* **148**, 293-6(1925).—If a metal conglomerate is cut and then etched on the cut surface, light is reflected from the crystallite faces in certain well-defined maxima as the conglomerate is rotated about a normal to the cut surface. These maxima occur 4, 3 or 2 times in a complete rotation of the sample, corresponding to reflection from the cube, octahedral and dodecahedral planes, resp. By detg., with the aid of a microscope, the relative nos. of reflecting planes in different positions of the sample, it is possible to det. the probability of the occurrence of each kind of face. This probability may be calcd. for a haphazard orientation. Only in a conglomerate with purely chance orientation will the direction of the cutting plane have no effect upon the measured probability for each crystal face.

R. J. H.

The flow of solid matter, especially natural salts. F. RINNE. *Z. Krist.* **61**, 389-424(1925).—R. discusses the behavior under pressure of amorphous material, single crystals and cryst. aggregates and the effect of time and temp. Optical and X-ray observations are given for deformed NaCl and KCl. The geological flow of salts is briefly considered.

L. S. RAMSDELL

Vaporization of crystals. G. AMINOFF. *Z. Krist.* **61**, 373-9(1925).—A. shows that vaporization in crystals is a vector property, analogous to soln. Spheres cut from crystals of thymol developed recognizable crystal faces when vaporized under reduced pressure.

L. S. RAMSDELL

Experiments upon the solution of concave forms (etch figures) upon crystals. G. FRIEDEL. *Bull. soc. franç. mineral.* **48**, 6-11(1925).—Definite chem. compns. of solns. favor the development of certain crystallographic forms. The process may be reversed in dil. solns. By controlling the compn. of the solvent, the rate of soln. of various faces on crystals of *K-alum* was controlled.

C. B. SLAWSON

Modulus of elasticity, temperature and melting point. W. WIDDER. *Physik Z.* **26**, 618-22(1925).—The modulus of elasticity is assumed to be a linear function of the temp. and approaches zero at the m. p. The m. ps. of a paraffin and a wax are thus detd. to be 45.1° and 49.0° , resp. After correlating the data in the literature on the modulus of elasticity, and with the above assumptions, W. calcs. the m. ps. of Fe, Cu and Al to be: 1532.8° , 1083.6° and 657° , resp., which are in very good agreement with the exptl. results. The testing of this method for other metals must await more accurate exptl. data on the variation of the modulus of elasticity with the temp.

J. H. PERRY

Variation of logarithmic decrement with amplitude and viscosity of certain metals. II. G. SUBRAHMANYAM. *Phil. Mag.* **50**, 716-22(1925); cf. *C. A.* **19**, 2151.—Logarithmic decrement and amplitude curves have been constructed for Al, Fe, eureka (constantan), manganin, and German silver. With the first 3 solids the decrement remains const. over a certain range and then increases linearly. For manganin the value is const. within the amplitude used. The logarithmic decrement for wires made of German silver does not tend to any const. value, but falls off steadily for decreasing amplitudes. Viscosities of these materials are: Al 2.763×10^8 , Fe 14.16×10^8 , eureka 1.506×10^8 , manganin 1.101×10^8 , and German silver 9.067×10^8 dynes per sq. cm.

S. C. L.

Isotherms of monatomic substances and of their binary mixtures. XXV. Same

of diatomic substances. **XXI.** The compressibility of hydrogen and helium between 90° and 14° absolute. F. P. G. A. J. VAN AGT AND H. KAMERLINGH ONNES. *Verslag. Akad. Wetenschappen Amsterdam* **34**, 625-37(1925).—The work of Onnes and Martinez (C. A. **18**, 1219) was continued at lower temps. The values of A and B in the empirical equation $p = A + Bd + Cd^2 \dots$ were accurately detd. from 14° to 90° K. for H_2 , $16-70^\circ$ K. for He. The Boyle point of He was found to be at 22.1° K. From these data the corrections are derived applicable in this temp. region to the temp. scale of the international H_2 and He thermometers. The measurements confirmed the view of O. and M. that there is no reason to adopt a term due to quantum influence ($Qd^{3/2}$) in the equation of state.

B. J. C. VAN DER HOEVEN

Isotherms of diatomic substances and of their binary mixtures. XXXII. The behavior of hydrogen relative to the law of corresponding states. F. P. G. A. J. VAN AGT. *Verslag. Akad. Wetenschappen Amsterdam* **34**, 638-43(1925).— B and t from the measurements in the preceding abstract are transformed into the "reduced" B and t quantities of the law of corresponding states. $B = f(t)$ curves for He, A, Ne, H_2 , N_2 , and O_2 are compared (partly using values of Cath and Onnes). Above $t = 1$ the values spread out according to the crit. temps. The curves all seem to intersect at a point very near $t = 1$.

B. J. C. VAN DER HOEVEN

The theories of state of matter. II. Internal pressure, co-volume and association. F. SCHUSTER. *Ber.* **58B**, 2183-6(1925); cf. C. A. **19**, 3394.—The internal pressure of a substance can be measured but cannot be directly related to mol. constitution. Mol. co-vol., on the other hand, is not easily measurable, but forms a basis for the calcul. of degree of association, which is one way of expressing mol. constitution. By means of simple equations connecting internal pressure and co-vol. it is possible to obtain information as to mol. association from a knowledge of internal pressure. The equations are: $b_s = v_s - (RT_c)/B_s$ and $b_k = (RT_c)/(8p_k)$. Where b_s = the van der Waals co-vol. at the b. p. in l. v_s = the mol. vol. at the b. p. in l. R is the gas const. in l-atm., T_c = the abs. b. p., B_s = the internal pressure at the b. p. in atm., b_k = the van der Waals co-vol. at the crit. pt. in l. and T_c and p_k are the crit. temp. and pressure, resp. With these equations S has calcd. the 4 values ($v_s - b_s$), b_s , b_s/b_k and $(v_s - b_s)/b_s$ for 20 inorg. and 29 org. substances. The B_s values are taken from a previous publication of S.'s (C. A. **19**, 3394), the v_s values from Walden (C. A. **3**, 2077), and the other necessary values from van Laar (Die Zustandsgleichungen Leipzig 1924). For normal, non-associated substances it was found that $b_s = 0.64 b_k$ and $v_s - b_s = 0.23 b_k$. These conclusions are compared with Traube's results obtained by a different method (*Ber.* **30**, 265(1897)). Small errors in the values for the crit. temp. make large errors in the ratios as calcd. by these equations.

R. L. DODGE

The vapor pressures of solid and liquid cyanogen. J. H. PERRY AND D. C. BARDWELL. *J. Am. Chem. Soc.* **47**, 2629-32(1925).—The vapor pressures of $(CN)_2$ were measured from -93° to the triple point for the solid and from the triple point to -7° for the liquid. The equations for the solid and liquid are, resp., $\log_{10} P(\text{mm.}) = (-1695.122/T) + 9.65530$, and $\log_{10} P(\text{mm.}) = (-1818.554/T) - 5.0813 \log_{10} T + 22.30083$. The calcd. triple point is -27.90° at 552.2 mm. The normal b. p. is -21.17° . The heats of sublimation, fusion and vaporization have been calcd.

J. H. P.

The viscosity of liquids under pressure. P. W. BRIDGMAN. *Proc. Nat. Acad. Sci.* **11**, 603-6(1925).—The viscosities of 43 liquids have been measured in the pressure range between atm. and 12,000 kg./cm², and at 30° and 75° . H_2O is unique in that at low temps. and pressures its viscosity decreases with rising pressure, while above 25° the min. disappears and the viscosity increases just as it does for all the other liquids at all temps. Beyond a pressure of about 1000 kg. the rate of increase is so rapid that a logarithmic curve is necessary. The increase under 12,000 kg. varies from 10-fold for MeOH to at least 10^7 -fold for eugenol. There is a correlation between the increase in viscosity under pressure and the complication of the mol., particularly well-marked in homologous series. Phillips' theory that viscosity is a function of vol. only, and Brillouin's theory involving a more complicated vol. function are both proven far from correct. An actual interlocking effect between mols. must be taken into account.

GEORGE L. CLARK

The Darcy filtering law. OTTO EMERSLEBEN. *Physik. Z.* **26**, 601-10(1925); cf. *Bautechnik* **2**, 73-6(1924).—Mathematical. An application of the zeta function to a study of the flow of ground water.

J. H. PERRY

The behavior of crystals and lenses of fats on the surface of water. I. The mechanism and rate of spreading. ARTHUR CARL AND E. K. RIDEAL. *Proc. Roy. Soc. (London)* **109A**, 301-17(1925).—An exptl. study of the process of surface spreading

on H_2O and 0.01 N HCl solns. of org. compds. contg. a long chain terminating in a polar group, including acids, esters, ethers, phenols and nitrites proves that monomol. films spread from crystals as well as lenses, and that a definite equil. surface tension or 2-dimensional pressure characteristic of the substance is established. The method consisted in measuring the force which almost breaks a Pt ring through the surface by a chainomatic balance arrangement. The spreading of a cryst. fat on a H_2O surface takes place in two stages: (1) the surface is covered with a monomol. film under 0 compression. The rate at which myristic acid mols. leave a crystal is 36.2×10^{13} mols. per sec. per cm. of length of the crystal face, giving an av. life on the surface of 0.60×10^{-7} secs. (2) The expanded film packs with increase in 2-dimensional pressure till equil. results between surface soln. and recondensation. For expanded films a simple eqn. of state is obeyed: $F = K'[(1/a) - (1/a_0)]$ where F is the surface pressure, a and a_0 are the areas per mol. at F and $F = 0$ resp. Hence there is a limit of expansibility explained by inelastic mol. collisions in the surface. Spreading oil films appear to be pushed out from the source (lens or crystal) by the further entry of mols. into the surface layer, rather than pulled over the surface by the attraction of uncontaminated H_2O . **II. The effect of temperature on the equilibrium pressure.** *Ibid* 318-30. This effect is considered in detail for films of fatty acids and their esters. The stability of monomol. films is directly related to this equil. pressure. With some compds. the water-oil interfacial tension rises with increasing temp. Such an interface can exist in either of 2 modifications corresponding to the condensed and expanded states. The phenomena are discussed from the standpoint of the phase rule. By an application of the Clapeyron eqn. the latent heats of fusion of some of the compds. are calcd. **III. The effect of the polar group on the equilibrium pressure.** *Ibid* 331-8. The expts. of Part II are extended to other long-chain compds. with more complicated polar heads. No general conclusions are possible except that one portion of the curves is detd. by the hydrocarbon chain and another by the polar group. The same must be said of expts. with impure compds. and mixts. The course of the temp.-surface tension curves is extremely sensitive and only the very purest materials yield the parallel linear curves. Cf. also *Nature* 115, 457-9(1925). G. L. CLARK

Polymolecular and monomolecular films. W. D. HARKINS AND J. W. MORGAN. *Proc. Nat. Acad. Sci.* 11, 637-43(1925).—New measurements have been made of the spreading of several liquids on water or on aq. solns of CaCl_2 , and on the collapse of compressed films. Monomol. films are formed by the following arranged in the order of increasing mean thickness (in \AA . U.) at collapse: phenyl-dibiphenyl-methyl-amine on CaCl_2 (8.4); phenanthrol on CaCl_2 (12); stearic acid on H_2O (30); *sym*-di-*β*-tri-phenylethylurea on CaCl_2 (14); on H_2O polymolecular, (42). The following form polymol. films: 9,10-dibromanthracene on CaCl_2 (111); Ph_3CCN on CaCl_2 (120); phenanthrene on CaCl_2 (132); di-*β* naphthylamine on H_2O (158); hexachlorobenzene on CaCl_2 (248); α -bromonaphthalene (105). The solns. of CaCl_2 have the advantage that the surface tension is 100 as compared with H_2O , 72, and hence that many liquids will spread on it which have a negative coeff. on H_2O . Young's moduli are detd. for the films; steel is 12,000, stearic acid on H_2O , 39, and dibromanthracene (polymol.) <2. Two substances each of which forms a monomol. film, also form a monomol. film when they are mixed. Several of these are studied in detail as above. G. L. CLARK

The oriented-wedge theory of emulsions. W. D. HARKINS AND NORVIL BEEMAN. *Proc. Nat. Acad. Sci.* 11, 631-7(1925). Finkle, Draper and Hildebrand (*C. A.* 18, 607) and Harkins and Keith (*C. A.* 18, 2095) found exptl. evidence for the oriented wedge theory of Harkins, Davies and Clark (1917) in the dependence of size of the drops in emulsions upon the positive ion of the emulsifying soap (decreasing as the ion size increases from Na to Cs). New measurements under more carefully controlled conditions seem to invalidate these exptl. interpretations, for the drop distribution curve is the same in stanolax emulsions for Na, K or Cs soaps. This in no way affects the oriented-wedge theory but points to ionization of the soaps and to the improbability of a mol. of soap being able to affect a drop with a radius at least 250 times greater (the diam. of the greatest no. of drops is 15,000 \AA . U. as compared with a soap mol. length of about 30 \AA . U.). G. L. CLARK

The surface-tension crystal vs. saturated solution. The concentration cell: finely divided salt|supersaturated solution|saturated solution|large crystals. LEO SOEP. *Phil. Mag.* 50, 675-81(1925).—A mathematical treatment of the e. m. f. of the above cell. S. C. L.

The statistical foundation of Volmer's equation of state for adsorbed substances and the formula for the concentration. S. C. KAR. *Physik. Z.* 26, 615-8(1925).—An application of quantum statistics proves: (1) that Volmer's equation of state,

$(\pi(\Omega - \beta) = R T$, where π is the decrease of the surface tension of the liquid adsorbent, Ω is the surface concn. per mole of the adsorption layer, and R is the gas const.) is correct; (2) that the formula for the concn. is not that of Volmer but is identical with Langmuir's formula, $c = k/(1 - \eta\beta)$ where $\eta = 1/\Omega$ and $c = 1/v$; and (3) that $k = (2M)^{1/2}(\pi)^{1/2}(kT)^{1/2}e^{-\alpha/KT}$ where M is the mol. wt., α the vaporization or adsorption potential per mol., N is Avogadro's no.; and k is Planck's const. J. H. PERRY

Adsorption and superficial energy of interfacial boundaries. BORIS ILIIN. *Physik. Z.* 26, 497-501(1925).—The equations of Gibbs and Sziszkovski (Sziszkovski, *C. A.* 3, 133; Rehinder, *C. A.* 19, 1079), also Langmuir's (*C. A.* 11, 2849, 39, 1848(1917)), are shown to apply satisfactorily to data in the literature on gas-soln., vapor-liquid and solid-gas systems. The ratio of superficial energies at the boundary depends on the surface tension of the sep. phases *in vacuo*. G. CALINGAERT

Emulsification of sodium stearate and sodium palmitate. N. A. JAJNIK AND BAKSH ILAHI. *Kolloid-Z.* 37, 139-44(1925).—The emulsifying power of Na stearate and Na palmitate has been compared by detn. of the smallest quantity of soap which was just sufficient to emulsify equal vols. of different oils. The purity of the soaps was very important. They were prepd. by neutralizing solns. of stearic or palmitic acid in 98% alc. with a soln. of Na_2CO_3 , evapg. to dryness and then extg. with 98% alc. The final vol. of soap soln. and oil used for each emulsion was 100 cc. The curves (wt. of soap in g. with cc. of oil) of cottonseed and poppy-seed oils were similar and those of mustard-seed, sesame, olive and coconut oils were of the same type. For each increase of 10 cc. of oil the amt. of soap increased but this increase in amt. of soap was not directly proportional to the increase in vol. of oil, i. e., the emulsifying power of the soap increased with increase in concn. In general the emulsifying power of Na palmitate was > that of Na stearate. The soap soln. with the lowest surface tension possessed the greatest emulsifying power. H. M. McLAUGHLIN

The action of protective colloids. I. TRAUBE AND E. RACKWITZ. *Kolloid-Z.* 37, 131-8(1925).—The theory proposed considers 3 adhesion intensities: (a) that of the protecting colloid to H_2O ; (b) that of the colloid to be protected to H_2O ; (c) that of the 2 colloids towards one another. Surface-active substances, such as saponin, soap and salts of bile acids, possess less adhesion intensity to H_2O and should exert less protective action than surface-inactive substances, such as gelatin, albumin and dextrin having a high adhesion intensity to H_2O . In order to test the theory protective nos. of surface-active and surface-inactive colloids were detd. by methods similar to Zsigmondy's Au no. detns. The surface-active colloids frequently exerted little protective action on lyophobic colloids, e. g., sols of Au, Ag and C but with other colloids, e. g., S and As_2S_3 , possessing less adhesion intensity to H_2O this difference in the behavior of surface-active and surface-inactive colloids was not evident. A new method for detn. of the protective colloid action is given which depends on the distribution of the dissolved colloid, e. g., Au or Ag, in the presence of a protective colloid between 2 solvents, e. g., H_2O and CHCl_3 , C_6H_6 , CCl_4 or CS_2 . By shaking an aq. soln. of a lyophobic sol contg. a small quantity of a surface-inactive substance as a protective colloid with CHCl_3 or C_6H_6 , the lyophobic sol (Au or Ag) was removed quant. from the H_2O phase and formed a CHCl_3 or C_6H_6 emulsion. Under the same conditions with a surface-active protective colloid present in any amt. the entire quantity of lyophobic sol remained in the H_2O phase. The results are explained by the consideration that the lyophobic colloid adheres to the surface-inactive colloid and then the gelatin with the Au encloses the little drops of CHCl_3 ; but the surface-active colloid because of its smaller adhesion intensity to the Au does not adhere to the Au particles. H. M. McL.

Solubility of hydrogen selenide. AYA JOSEPHINE McAMIS AND W. A. FELSING. *J. Am. Chem. Soc.* 47, 2633-7(1925).—At a pressure of 1 atm. of H_2Se its soly. in water falls from 0.09789 mole per l. at 14° to 0.07317 mole per l. at 35° . The soly. at 1 atm. pressure and 25° in solns. of HI increases from 0.08415 mole per l. in H_2O to 1.11012 mole per l. in a soln. contg. 2.73 moles HI per l. Calcd. from the preceding values, the heat of soln. in water at 25° is 2431 cal. per mole of H_2Se and the free-energy decrease for the reaction H_2Se (1 mole) = H_2Se (760 mm.) is approx. 1450 cal. JAMES M. BELL

Solubility relations of isomeric compounds. I. Introduction. JOHN JOHNSTON. *J. Phys. Chem.* 29, 882-8(1925).—An introduction to the study of the equil. relations between ortho, meta and para isomers. In many systems of the 3 isomers of a given compn., the soly. of any one component in mixt. with either of the others or with both is in accordance with the law of the ideal soln. and is therefore calculable from a small no. of consts. pertaining to the pure components. The theory of ideal solns. is discussed and it is shown, in the case of such solns., that the complete ternary diagram may be constructed from 6 observations, 3 of which are the melting temp. of the pure

components; the other 3 are the heats of melting or appropriate soly. measurements, which, in general, are simpler to carry out. II. **Determination of freezing temperatures on binary mixtures.** D. H. ANDREWS, G. T. KOHMAN AND JOHN JOHNSTON. *Ibid* 914-25.—An app. is described for making accurate time-temp. curves for systems such as the disubstituted benzenes singly or in binary or ternary mixts. The effective temp. head is controlled and measured; only about 1 cc. of material is needed and its temp. is read by means of a thermo-element of small heat capacity and small lag. The theory of cooling curves under a controlled temp. head is discussed on the basis of Newton's law, which is found to be valid for the app. This leads to a mode of interpreting the cooling curve of a binary mixt. which yields correct results. III. **Mutual solubility of the three dinitrobenzenes.** D. H. ANDREWS. *Ibid* 1041-7.—Complete data on the neutral soly of the dinitrobenzenes derived from observations of freezing temp. are given and compared with results calcd. from coulometric data by means of the law of ideal solus. The solns. are found to differ slightly, if at all, from the ideal, implying that the crystals of each isomer from mixts with the other 2, are pure and that the mixing is not attended by an appreciable change in heat content or vol. Data are given on the soly. of each isomer in several solvents. The data depart comparatively little from the ideal curve.

HARRY B. WEISER

The conductivity of uni-univalent salts in methanol at 25° C. J. E. FRAZER AND HAROLD HARTLEY. *Proc. Roy Soc. (London)* 109A, 351-68(1925).—The elec. cond. between 0.0001 and 0.002 N of 15 univalent salts in MeOH is measured and confirmation of the applicability of Kohlrausch's law of independent mobility of ions obtained. Kohlrausch's square root relation holds good within the range of concn. examd. In this respect the results are in complete accord with Debye and Hückel's theory of cond. but in other respects the theory may require modification; for example the differences in slope in the cond. curves for salts with almost the same values for l_a and l_c (mobilities of single anions and cations) such as KI, KNO₃ and AgNO₃ are incompatible with the D and H equations. In MeOH as in H₂O the mobilities of the ions of alk. metals increase with increasing at. no. and at. wt. but the rise in MeOH is more regular; for the halogens there is a regular rise which is not true in aq. solns., since the value for Br is highest. The relative speeds in MeOH are lower than would be expected from its low viscosity; $l_{\text{MeOH}}/l_{\text{H}_2\text{O}} = \eta_{\text{H}_2\text{O}}/\eta_{\text{MeOH}}$ (viscosity) = 1.64 in accordance with Stokes' law is not found true.

G. L. CLARK

Note on the theory of interionic attraction in strong electrolytes. S. R. PIKE AND G. NONHEBEL. *Phil. Mag.* 50, 723-8(1925).—P. and N. discuss the applicability of the Milner and the Debye and Hückel equations for the properties of electrolytic solns. At the lowest concn. in HCl and TiCl solns. examd. by Randall and Vanselow (*C. A.* 19, 428) the actual curves for f - p lowering fall about half way between those of M. and of D. and H.

S. C. L.

The activity coefficients and transport number of solutions of hydrogen chloride in methanol. GORDON NONHEBEL AND HAROLD HARTLEY. *Phil. Mag.* 50, 729-49 (1925).—The activity coeff. and transport nos. of solns. of HCl in CH₃OH have been obtained by measurements of e , m , f . The activity coeffs. of HCl in the 3 solvents, H₂O, CH₃OH and C₂H₅OH, agree fairly well with those calcd. from Milner's equation for the interionic elec. energy in a soln. of a completely dissociated electrolyte, but do not agree with those calcd. from Debye's equations. The relation between the activities of electrolytes in different solvents has been pointed out, and it has been shown how the partial pressure of HCl over its solns. in one solvent may be calcd. from its vapor pressure over a second solvent and a series of e , m , f measurements in both solvents.

Ionic equilibria across semipermeable membranes. NAOTO KAMEYAMA. *Phil. Mag.* 50, 849-64(1925).—The expts. of Donnan and Allmand on the unequal distribution of KCl across a Cu ferrocyanide membrane between a pure aq. soln. and one contg. K ferrocyanide have been recalcd. and discussed from the point of view of activity and the ionic strength principle of G. N. Lewis. Except when the KCl concn. is small in comparison with that of the ferrocyanide, the results of the distribution equil. expts. of Donnan and Allmand are in agreement with the ionic strength principle. New expts. carried out with a more reliable method of analysis and an improved technique render it probable that the marked deviations from the ionic strength principle referred to are due to exptl. errors.

Optical research on electrolytic aqueous solutions. A. HEYDWEILLER. *Physik. Z.* 26, 526-56(1925).—A comprehensive review of the work done by H. and his collaborators over the period 1910-1914 and abandoned since. Includes density, refraction, absorption, magnetic rotation. 36 references.

G. CALINGAERT

The influence of traces of water on solution equilibria. I. ERNST COHEN AND W. D. J. VAN DOBBENBURGH. *Verslag Akad. Wetenschappen Amsterdam* **34**, 518-29 (1925).—Salicylic acid was recrystd. in 3 ways: from water, crystals dried over P_2O_5 , from ether (redistd. over P_2O_5) and from benzene (also redistd.). The soly. of these preps. in benzene at 30.50°, approaching equil. from high and from low temps. and using different samples of salicylic acid, varied from 1.03 to 1.38 (g. per 100 g. satd. soln.), depending upon the previous history of the acid; preps. recrystd. from H_2O always showed the higher values. This phenomenon is due to the influence of minimal traces of water, occluded in the crystal during crystn. Whereas the soly. of salicylic acid in dry benzene was found to be 1.01, a water content of 0.00147% caused it to increase to 1.05; 0.00374% to 1.10; 0.00682% to 1.19; 0.01042% to 1.31; 0.01478% to 1.35; excess water to 1.36. On this phenomenon a method may be based for the detn. of small amts. of water in crystals.

B. J. C. VAN DER HOEVEN.

Equilibria in systems in which phases are separated by a semipermeable membrane. X. F. A. H. SCHREINEMAKERS. *Verslag Akad. Wetenschappen Amsterdam* **34**, 530-8 (1925).—Previous papers are continued (C. A. **19**, 3200). Properties and conditions are discussed of systems with more than 1 membrane and with a double membrane.

B. J. C. VAN DER HOEVEN

The mechanism of gaseous chemical reactions. M. KROGER. *Z. physik. Chem.* **117**, 387-431 (1925).—Answers are sought to the 2 questions. (1) is there any such thing as a pure monomol. gaseous decompn. reaction proceeding without mol. collisions? and (2) is there any such thing as an exothermic binol. reaction in which at the moment of reaction no other mols. or atoms are in close proximity to the reaction pair? A ray of I mols., traveling through a highly evacuated glass vessel, passed in its path axially through a tubular Pt foil heated electrically. The side of the glass vessel on which the ray impinged was cooled in liquid air and the character of the I deposit on the glass gave an indication of the amt. of dissociation of the I mols. into atoms that had been caused by the radiant energy emitted from the foil. The I ray was produced by vaporizing I through an aperture, the walls of which were cooled by liquid air. The entire system was continuously evacuated to less than 10^{-6} mm. Hg to avoid disturbances from other gases. The Pt heater was maintained at temps. from 775° to 1100°. For a given temp. (rate) of vaporization, chosen as 29.3°, the time taken to deposit a definite amt. of I on the glass opposite the aperture was measured. The amt. deposited was measured by the change in color of the thin film. The time necessary to bring about a color change from gray to green, with no current through the heater, was chosen as the standard. It was assumed that if dissociation of the I mols. in the ray took place under the influence of the Pt heater, the atoms so formed would be expelled in such directions that they would not condense on the same spot as the undissociated mols. As a result the time taken to form the film of standard thickness would be increased in proportion to the amt. of dissociation. No evidence was obtained to indicate dissociation of I mols. greater than 1%, the limit of accuracy of the measurement. Two methods were employed in attacking the second problem. The reactions chosen were $Cd + I_2$, $Cd + Se_8$ and $Cd + S_8$. The rays of Cd and I, Se or S, produced as above, were caused to cross at an angle inside an evacuated vessel in such a way that the Cd and I, Se or S deposits were made on opposite sides of the vessel. The space between the 2 deposits was closely examd. for the reaction product. The color change of the deposit was used as a measure of the amt. formed. The reaction product deposited in these expts. was so small that it was masked by the normal scattering of the reacting materials from their respective rays. The second method consisted in causing the beams to cross in a vessel immersed in liquid O. The amt. of O evapd. was a measure of the combined energy liberation due to latent heat of vaporization of the reactants and heat of reaction. The former was measured by blank detns. with the reactants singly. With $Cd + S_8$ a more rapid vaporization of liquid O was observed than for the reactants singly. Chem. analysis of the deposit confirmed the belief that with $Cd + S_8$ there was observed a chem. union by collision of a poly-at. mol. with 1 or 2 atoms. Details of experimentation with at. and mol. rays are given.

R. L. DODGE

Catalytic action of colloidal metals of the platinum groups. XVII. Colloidal cobalt. C. PAAL AND HANS BORTERS. *Ber.* **58**, 1542-6 (1925); cf. C. A. **8**, 3275.—The different preps. of colloidal $Co(OH)_3$ in aq. soln. were reduced with H_2 in the presence of colloidal Pd-hydrosol, in an app. as described by Paal and Gerum (cf. C. A. **2**, 1729). During the first 3 days the reduction proceeded at room temp. and atm. pressure but during the remaining 4-11 days the temp. was 50° and the pressure was increased by 100 mm. Hg. Of the 3 preps. (cf. C. A. **20**, 4) 2 were used in solid form: (1)

prepd. with Na protalbate as the protective colloid and oxidized with air; (2) prepd. with Na lysalbate as the protective colloid and oxidized with H_2O_2 ; and one was used in gel form, (3) prepd. with Na protalbate as the protective colloid and oxidized with H_2O_2 . The relative quantities of $\text{Co}(\text{OH})_3$ used in (1), (2) and (3) considered as the ratio Co:Pd were, resp., 9:1, 23:1 and 10:1. The $\text{Co}(\text{OH})_3$ was completely reduced to the metal as shown by: (a) the fact that the cc. of H_2 used was very slightly > the theoretical amt. required for reduction; (b) analysis of the product for Co; (c) the amt. of H_2 formed by treating the product with dil. H_2SO_4 . H. M. McLAUGHLIN

The catalytic splitting of acetoacetic acid by strong acids and bases. HANS V. EULER AND ARNE ÖLANDER. *Z. anorg. allgem. Chem.* **147**, 295-311(1925).—The catalytic splitting of acetoacetic acid and its salts differs from the usual splitting of esters of org. acids in that (1) the reaction products are different in acid and alk. solns., and (2) the rate of reaction is not proportional to the H or OH-ion concn. In acid soln. the predominating reaction is $\text{CH}_3\text{COCH}_2\text{COOH} \rightarrow \text{CH}_3\text{COCH}_3 + \text{CO}_2$, while in strongly alk. soln. it is $\text{CH}_3\text{C}(\text{ONa})\text{CHCOONa} + \text{H}_2\text{O} \rightarrow 2\text{CH}_3\text{COONa}$. The reaction velocity const. for the 2 reactions were detd. at 37° over the alkali concn. range $p_{\text{H}} = 11.11$ to $p_{\text{H}} = 15.07$ (?). The observed const. were $p_{\text{H}} = 11.11$, $k_1 = 3.01 \times 10^{-5}$, $k_2 = 0$; $p_{\text{H}} = 13.21$, $k_1 = 3.37 \times 10^{-5}$, $k_2 = 0$; $p_{\text{H}} = 13.60$, $k_1 = 3.98 \times 10^{-5}$, $k_2 = 0.80 \times 10^{-6}$; $p_{\text{H}} = 13.90$, $k_1 = 1.52 \times 10^{-5}$, $k_2 = 2.18 \times 10^{-6}$; $p_{\text{H}} = 14.19$, $k_1 = 0$, $k_2 = 19.6 \times 10^{-6}$; $p_{\text{H}} = 15.07$, $k_1 = 0$, $k_2 = 130 \times 10^{-6}$. The reaction rates were detd. by measuring the acetone concn. of the soln. at definite time intervals. Both reactions were considered monomol. The acetone was detd. by the Messinger-Hupfer iodometric method (cf. *Ber.* **21**, 3366(1888)). The H-ion concn. was measured electrometrically. It is probable that the acid and basic catalysts act on different parts of the acetoacetic acid mol. through the intermediation of ions. In strongly alk. soln. the splitting probably takes place at the enol groups of the acetoacetic salt.

R. L. DODGE

The composition of reduced nickel catalysts. BENNOSUKE KUBOTA AND KIYOSHI YOSHIKAWA. *Sci. Papers Inst. Phys. Chem. Research* **3**, 223-31(1925).—A reduced Ni catalyst has not one definite form but is composed of many active unstable hydrides coexisting in the catalyst. The nature and no. of these hydrides depend on the reduction temp. The hydrides can be sepd. into 3 classes according to their sp catalyzing power: (1) those capable of hydrogenating the aromatic nucleus, (2) those capable of hydrogenating ethylenic compds. and (3) those capable of hydrogenating at. groups such as nitro groups. The activity of each of these classes can be completely and selectively destroyed by suitable poisons. Those of the first class are poisoned by thiophene, the second by Pt_2S and the third by H_2S . The relative amts. of each class of hydrides are detd. by measuring the sulfide content of the Ni catalyst when it has become completely and successively poisoned for each of the 3 hydrogenation reactions. Such detns., carried out on catalysts that had been reduced at 250°, 350°, 450°, 550°, 650°, and 700°, showed that the amt. of all 3 classes of hydrides was decreased by increasing the reduction temp. but that the ratios of the 3 classes remained essentially the same. By a calcn. based on the sulfide content of the poisoned catalysts Y. assigns hypothetical formulas to the active Ni hydrides, ranging from NiH_2 to Ni_{10}H_1 , depending on the reduction temp.

R. L. DODGE

The effect of X-rays on the platinum catalyst in the contact sulfuric acid reaction. G. L. CLARK, P. C. McGRATH AND M. C. JOHNSON. *Proc. Nat. Acad. Sci.* **11**, 646-51(1925).—X-rays do not activate the Pt catalyst when it is rayed in an atm. of dry air. At 300° the conversion in the presence of 0.0130 g. H_2O per g. of air is increased from the dry value of 3.25% to about 88%; after irradiation for 3 hrs. with X-rays from a W tube at 100,000 v. the conversion rises to 94%. This value is maintained for 5 hrs., followed by a rapid drop to below the unrayed value, a subsequent recovery to over 87% after 9 hrs.—and a gradual decrease to a const. value of 84.3%. After a second raying the rise is only to 87% with a final return to the same value of 84.3%. A satisfactory lab.-scale app. and method of sepn. of SO_2 and SO_3 , depending upon the pptn. of SO_2 mist and its filtration in Gooch funnels, are described.

G. L. CLARK

Binary mixtures. J. SAMESHIMA. *J. Faculty Sci. Tokyo Imp. Univ.* **1**, 63-103(1925); cf. *C. A.* **12**, 2470.—S. presents a simplified Duhem-Margules' equation for the partial pressures of the 2 components of a binary mixture: $p_1 = p_1^0 e^{(1-x)^2\alpha}$; $p_2 = p_2^0(1-x)e^{x^2\alpha}$, where p_1 , p_2 = partial pressure of components, P_1 , P_2 = their satn. pressures in the pure state at the same temp., x = mol. fraction of 1st component in the liquid phase, α , exptl. const., which is shown to be: $\alpha = \ln[(1/P_1)((dP/dx)_{x=0} + P_1)]$ and $\alpha = \ln[(1/P_2)((dP/dx)_{x=1} + P_1)]$. α can thus be detd. from the known values of P_1 and P_2 , plus the slope of the total pressure curve (P) at either end. Aver-

aging the 2 values so obtained in the case of $C_6H_6-CS_2$; Me_2CO-Et_2O ; $CCl_4-C_6H_6$; $EtI-EtOAc$. S. obtains calcd. values of p_1 and p_2 which are in very good agreement with the exptl. data. In a further section S. shows the additivity of the dielec. const. ($D-1$) for non-associated liquids, and calcs. the degree of association of $EtOH$ at 18° from the deviations from additivity for an $EtOH-Et_2O$ mixt.

G. CALINGAERT

Ternary systems. III. Silver perchlorate, toluene and water. A. E. HILL AND F. W. MILLER, JR. *J. Am. Chem. Soc.* **47**, 2702-12(1925).—The soly. of $AgClO_4$ in C_7H_8 has been detd. from -73.5° to $+75^\circ$. At room temp. (25°) the soly. is 50.3%. Below 22.6° the solid phase is the compd. $AgClO_4 \cdot C_7H_8$. The ternary system, $AgClO_4-C_7H_8-H_2O$, has been studied from the ternary eutectic at -94° up to $+91.75^\circ$. There exist 7 quintuple points, each of which was detd., and 20 4-phase equilibria. The system shows, in addn. to the soly. curves for the 3 solid phases ($AgClO_4$, its hydrate and its compd. with toluene), 2 binodal curves, one of which is submerged and does not reach any of the 2-component axes at any temp. The intersection of the 2 binodal curves, at certain points which are not their plait points gives rise to a 3-liquid system which is stable from -24.1° to above $+90^\circ$.

JAMES M. BELL

Carbon dioxide-ammonia compounds. ROBERT MEZGER AND THEO. PAYER. *Gas u. Wasserfach* **68**, 651-5, 672-5, 687-91(1925).—Vapor-tension detns. are presented by tables and curves for a large no. of systems including the following aq. solns: those contg. 2% NH_3 only; 5 solns. contg. 2% NH_3 , and amts. of CO_2 corresponding to various possible definite compds., between 10° and 80° ; 6 solns. of from 1 to 4% NH_3 only, between 10° and 40° ; 19 solns. contg. 2% NH_3 and with NH_3/CO_2 ratio varying from 1/1 to 1/2.7, at 25° only. The application of the data presented to the control of NH_3 recovery systems is discussed briefly.

WM. B. PLUMMER

Systematic affinity principle. XXXII. Higher ammoniates of halides in the iron group. WILHELM BILTZ AND ERICH RAHLFS. *Z. anorg. allgem. Chem.* **148**, 145-51 (1925); cf. *C. A.* **19**, 3226.—Isothermic decompn. curves at -78.5° and tension curves were detd. of Mn, Fe, Co and Ni halide ammonia compds. Five new compds. were found from these data and the following properties detd. (continuation of earlier work, *C. A.* **18**, 606): $MnCl_2 \cdot 10NH_3$: 7.28 cal. (heat of formation per NH_3 mole from the next lower compd.), -61° (temp. corresponding to an NH_3 pressure of 100 mm.), 11.15 cal. (total heat of formation from halide plus gaseous NH_3 per mole NH_3); $MnCl_2 \cdot 12NH_3$: 7.15 cal., -65° , 10.48 cal.; $MnBr_2 \cdot 10NH_3$: 7.16 cal., -64° , 11.78 cal.; $FeCl_2 \cdot 10NH_3$: 7.25 cal., -62° , 11.70 cal.; $CoCl_2 \cdot 10NH_3$: 7.20 cal., -63.5° , 12.02 cal. Nickel decammines could not be found. The $CoCl_2 \cdot 10NH_3$ is different in its properties from the one of Clark, Quick and Harkins (*C. A.* **15**, 456). The Mn and Fe salts were white, the Co salt was dull rose.

XXXIII. Ammoniates of beryllium halides. WILHELM BILTZ AND CARL MESSERKNECHT. *Ibid* 157-69.— $BeCl_2$ forms compds. with 2, 4, 6 and 12 mols. NH_3 . $BeBr_2$ binds 10, 6 or 4 mols. NH_3 , BeI_2 13, 6 or 4. All tetrammines decompose at high temps., giving NH_4Cl (ammonolysis); at 200° the chloride tetrammine gives diammine and NH_4Cl . From the vapor-pressure values the partial heat of formation (dissociation heat) of the ammine from the next lower NH_3 compd. was calcd.; the total heat of formation from salt + gaseous NH_3 was evaluated from detns. of the heat of soln. of the compd. in HCl . The 2 values are as follows (one value of the vapor-pressure curve is added, as far as this was measured (heat values per mole NH_3)): $BeCl_2 \cdot 12NH_3$: 7.77 cal., 16.5 cal., $p_{-50^\circ} = 168.3$ mm.; $BeCl_2 \cdot 6NH_3$: 8.04 cal., 25.4 cal., $p_{-50^\circ} = 90$ mm.; $BeCl_2 \cdot 4NH_3$: 18.12 cal., 34.1 cal., $p_{111^\circ} = 0.49$ mm.; $BeCl_2 \cdot 2NH_3$: (50.0 cal.), 50.0 cal.; $BeBr_2 \cdot 10NH_3$: 7.85 cal., 19.1 cal., $p_{-50^\circ} = 138.6$ mm.; $BeBr_2 \cdot 6NH_3$: 8.76 cal., 26.6 cal., $p_{-30^\circ} = 96.8$ mm.; $BeBr_2 \cdot 4NH_3$: 35.6 cal.; $BeI_2 \cdot 13NH_3$: 7.92 cal., 17.1 cal., $p_{-68^\circ} = 31.0$ mm.; $BeI_2 \cdot 6NH_3$: 8.90 cal., 27.9 cal., $p_{-30^\circ} = 69.1$ mm.; $BeI_2 \cdot 4NH_3$: 37.0 cal. It appears from these data that Be takes an extreme place with its tridecammine iodide and with total heat values for the ammine formation more than double the usual values, in many cases larger than heats of hydration.

XXXIV. Ammoniates of cadmium and mercury halides. WILHELM BILTZ AND CARL MAU. *Ibid* 170-91.—The following data were obtained for partial heat, total heat, both per mol. NH_3 , temp. corresponding to $p_{NH_3} = 100$ mm. and $d_{25^\circ}^\circ$: $CdCl_2 \cdot 1NH_3$: 18.1 cal., 18.1 cal., $+228^\circ$, 3.166; $CdCl_2 \cdot 2NH_3$: 16.5 cal., 17.3 cal., $+183^\circ$, 2.681; $CdCl_2 \cdot 4NH_3$: 10.7 cal., 14.0 cal., $+23^\circ$, 1.984; $CdCl_2 \cdot 6NH_3$: 10.2 cal., 12.7 cal., $+20^\circ$, 1.687; $CdCl_2 \cdot 10NH_3$: 7.4 cal., 10.6 cal., -54° ; $CdBr_2 \cdot 1NH_3$: 18.1 cal., 18.1 cal., $+228^\circ$, 4.012; $CdBr_2 \cdot 2NH_3$: 16.9 cal., 17.5 cal., $+188^\circ$, 3.350; $CdBr_2 \cdot 6NH_3$: 10.7 cal., 13.0 cal., $+42^\circ$, 2.069; $CdBr_2 \cdot 12NH_3$: 7.6 cal., 10.3 cal., -64° ; $CdI_2 \cdot 2NH_3$: 16.6 cal., 16.6 cal., $(+186^\circ)$, 3.641; $CdI_2 \cdot 6NH_3$: 11.68 cal., 13.3 cal., $+63^\circ$, 2.311. Complete discussion of the mol. vol. data will follow later. The expts. with $HgCl_2$ confirmed earlier work on the diammine (m. p. in NH_3 atm. 250°) and yielded 2 new compds.; with $HgBr_2$ one new compd. was found;

slightly more complicated are the relations for HgI_2 on account of the formation of a mixed compd. $\text{HgI}_2 \cdot \frac{4}{3}\text{NH}_3$ or more probably $2(\text{HgI}_2 \cdot \text{NH}_3)(\text{HgI}_2 \cdot 2\text{NH}_3)$, described by Francois (*Compt. rend.* **129**, 296(1899)). The following data were obtained: $\text{HgCl}_2 \cdot 2\text{NH}_3$: 25.6 cal., $d_4^{25} = 3.77$; $\text{HgCl}_2 \cdot 8\text{NH}_3$: 8.1 cal., 12.5 cal., -43° ; $\text{HgCl}_2 \cdot 9\frac{1}{2}\text{NH}_3$: 7.2 cal., 11.7 cal., -58° ; $\text{HgBr}_2 \cdot 2\text{NH}_3$: 16.2 cal., $d_4^{25} = 4.335$; $\text{HgBr}_2 \cdot 8\text{NH}_3$: 7.8 cal., 9.9 cal., -51° ; $\text{HgI}_2 \cdot \frac{4}{3}\text{NH}_3$: 13.0 cal., 13.0 cal., $+95^\circ$; $\text{HgI}_2 \cdot 2\text{NH}_3$: 11.5 cal., 12.5 cal., $+40^\circ$, $d_4^{25} = 4.45$; $\text{HgI}_2 \cdot 6\text{NH}_3$: 7.55 cal., 9.2 cal., -48° ; $\text{HgI}_2 \cdot 12\text{NH}_3$: no data given. The results of some other d. measurements are: $\text{HgCl}_2 \cdot d_4^{25} = 5.440$; $\text{HgCl} \cdot \text{NH}_3$: 5.381; HgBr_2 : 109; HgI_2 : 6.360 (red modification). Some observations are given on mercurous halides. $\text{HgCl} \cdot \text{NH}_3$ (about 14.8 cal.) occurs, also $\text{HgBr} \cdot \text{NH}_3$ (13.1 cal.). XXXV.

Ammoniates of aurohalides. WILHELM BILTZ AND WALTER WEIN. *Ibid* 192-206.—Pure AuCl was prepd from dry HAuCl_4 by slow evap. *in vacuo* (10 mm.) at temps. between 150° and 200° . Prepus from synthetic AuCl_3 were never sufficiently pure. AuBr was prepd. in a similar way and from this AuI . The data obtained follow. $\text{AuCl} \cdot \text{NH}_3$: 24.6 cal., 24.6 cal.; $\text{AuCl} \cdot 2\text{NH}_3$: 13.9 cal., 19.3 cal., $+80^\circ$; $\text{AuCl} \cdot 3\text{NH}_3$: 7.2 cal., 11.2 cal., -58° ; $\text{AuCl} \cdot 12\text{NH}_3$: partial heat not detd., vapor pressure equal to that of pure NH_3 , total heat about 9 cal.; $\text{AuBr} \cdot \text{NH}_3$: 22.7 cal., 22.7 cal.; $\text{AuBr} \cdot 2\text{NH}_3$: 12.2 cal., 17.5 cal., $+51^\circ$; $\text{AuBr} \cdot 3\text{NH}_3$: 8.3 cal., 14.4 cal., -43° ; $\text{AuBr} \cdot 4\text{NH}_3$: 8.1 cal., 12.8 cal., -44° ; $\text{AuBr} \cdot 6\text{NH}_3$: 7.95 cal., 11.2 cal., -46° ; $\text{AuI} \cdot \text{NH}_3$: 15.6 cal., 15.6 cal., $\text{AuI} \cdot 2\text{NH}_3$: 9.1 cal., 12.4 cal., -20° ; $\text{AuI} \cdot 3\text{NH}_3$: 8.9 cal., 11.2 cal., -25° ; $\text{AuI} \cdot 6\text{NH}_3$: 8.0 cal., 9.6 cal., -46° ; $\text{AuI} \cdot 8\text{NH}_3$: about 9 cal. XXXVI. **Ammoniates of cuprihalides.** WILHELM BILTZ, HANS BROHAN AND WALTER WEIN. *Ibid* 207-16.—Fifteen compds. were found, many forming easily mixed crystals (the $3\frac{1}{3}$ ammine is probably one). The color, sky-blue for $\text{CuCl}_2 \cdot 10\text{NH}_3$ becomes more deep for each halide series on passing the $3\frac{1}{3}$ compd. and is generally of a darker shade for the iodides. $\text{CuCl}_2 \cdot 2\text{NH}_3$: 21.9 cal., 21.9 cal.; $\text{CuCl}_2 \cdot 3\frac{1}{3}\text{NH}_3$: 14.1 cal., 18.8 cal., $+84^\circ$; $\text{CuCl}_2 \cdot 5\text{NH}_3$: 12.2 cal., 16.6 cal., $+58^\circ$; $\text{CuCl}_2 \cdot 6\text{NH}_3$: (8.4 cal., 15.2 cal.); $\text{CuCl}_2 \cdot 10\text{NH}_3$: 7.6 cal., 12.1 cal., -62° ; $\text{CuBr}_2 \cdot 2\text{NH}_3$: 21.0 cal., 21.0 cal.; $\text{CuBr}_2 \cdot 3\frac{1}{3}\text{NH}_3$: 15.6 cal., 18.9 cal., $+118^\circ$; $\text{CuBr}_2 \cdot 5\text{NH}_3$: 12.9 cal., 16.9 cal., $+68^\circ$; $\text{CuBr}_2 \cdot 6\text{NH}_3$: (9.1 cal.), 15.6 cal.; $\text{CuBr}_2 \cdot 10\text{NH}_3$: 7.8 cal., 12.3 cal., -61° ; $\text{CuI}_2 \cdot 2\text{NH}_3$: no data; $\text{CuI}_2 \cdot 3\frac{1}{3}\text{NH}_3$: 15.2 cal. (partial heat), $+109^\circ$; $\text{CuI}_2 \cdot 5\text{NH}_3$: 13.2 cal., $+75^\circ$; $\text{CuI}_2 \cdot 6\text{NH}_3$: (9.8 cal.); $\text{CuI}_2 \cdot 10\text{NH}_3$: 7.0 cal., -64° . B. J. C. VAN DER HOEVEN

The measurement of very low temperatures. XXXII. **The thermal dilatation of Jena glass 16 III.** F. P. G. A. J. VAN AGT AND H. KAMERLINGH ONNES. *Verslag Akad. Wetenschappen Amsterdam* **34**, 618-24(1925).—Of a Dewar one m. long glass the displacement of the inner wall, cooled to the b. p. of C_2H_6 , O_2 or H_2 was measured relative to the outer wall at room temp. (13.1°). The following changes in length were observed for 1000.00 mm glass: inner wall at $+97.8^\circ$ 0.671 mm; at -102.8° -0.770 mm; at -182.5° -1.176 mm; at -252.8° -1.294 mm; they can be represented by an equation $l = l_0[1 + 10^{-6}(at/100) + b(t/100)^2 + c(t/100)^3 + d(t/100)^4]$ with coeffs. $a = 716.8$; $b = 48.33$; $c = 9.02$; $d = 10.9$; t is the temp. The mean linear expansion coeff is between -97.8° and $+13.1^\circ$ $10^6\alpha_{1/2} = 7.93$; between $+13.1^\circ$ and -102.8° 6.64; between -102.8° and -182.5° 5.10; between -182.5° and -252.8° 1.65. This coeff. has at low temp. a temp curve similar to the sp.-heat curve with proportionality to T^3 (Debye) rather than to T (Born). B. J. C. VAN DER HOEVEN

The ratio of the specific heats of hydrogen. J. R. PARTINGTON AND A. B. HOWE. *Proc. Roy. Soc. (London)* **109A**, 286-91(1925).—Using the app. and methods previously described for use with air, CO_2 , O_2 and N_2 , P and H₂ find $C_p/C_v = \gamma = 1.4113 \pm 0.0002$; hence $C_p = 2.397$ and $C_v = 3.383$ g. cal. These values are compared critically with the results of previous investigators. G. L. CLARK

Heat of formation of lead carbonate. A. L. MARSHALL AND B. BRUZS. *J. Phys. Chem.* **29**, 1184-6(1925).—Correction. The last sentence in the abstract (C. A. **19**, 3114) and the summary in the journal should read: The values of ΔH (negative "heat of reaction") for $\text{PbO} + \text{CO}_2 = \text{PbCO}_3$ and $\text{PbO} + \text{PbCO}_3 = \text{PbO} \cdot \text{PbCO}_3$ are -21.1 and -0.34 K. cal., resp. B. BRUZS

The difference between several forms of thermodynamic principles. WITOLD JAJZYNA. *Physik. Z.* **26**, 622-8(1925).—A theoretical treatment of the conversion of heat into work and the detn. of the state of a substance. J. H. P.

The equation of state and its relation to the fundamental laws of thermodynamics. N. J. KOLTSCHIN. *Z. anorg. allgem. Chem.* **147**, 312-20(1925).—K. continues the work of R. Lorenz (cf. *Festschrift zur Jahrhundertfeier des Physikalischen Vereins*, Frankfurt, A. M. 1924) on the question as to the limiting conditions of the relation between

V and S within which the equation of state can be derived without restriction and in finite form from the general requirements (the first and second laws) of thermodynamics. He concludes that the condition $V = V(T)$ is not sufficient, but that it is further necessary that $S = S(vT)$. However, the equation of state in its differential form must not be inconsistent with the requirements $V = V(T)$ and $S = S(pT)$. These different conclusions, brought about by the presence of p or v in S , depend on the special form of the elementary work $dR = A p dv$. In a general case, however, if $dR = f_1 dd\phi + f_2 dv + f_3 dT$, where f_1, f_2, f_3 are condition functions, and under the conditions $U = U(T)$ and $S = S(vT)$, it is possible that the equation of state can appear in differential, not integrable form.

R. L. DODGE

The difference between several forms of the thermodynamic principle. WITOLD JAZYNA. *Physik. Z.* **26**, 622-8(1925).—A discussion of: (1) the transformation of heat into work, and (2) the detn. of the state of a substance, particular use being made of the $p-v$ diagram.

J. H. PERRY

Further experiments with liquid helium. X. The electrical resistance of pure metals, etc. XIV. The influence of elastic deformation on the superconduction of tin and indium. G. J. SIZOO AND H. KAMERLINGH ONNES. *Verslag Akad. Wetenschappen Amsterdam* **34**, 606-17(1925); cf. *C. A.* **18**, 495.—The resistance-temp. curve was detd. for a Sn wire 16.5 cm. long, 0.30 mm. diam. (30 ohms at room temp.) with and without an extending weight of 197 g. (2.52 kg./sq. mm.). The line on which the resistance disappears (at 3.7° K.), shifts slightly (0.007°) to higher temp. (as detd. from He pressure) under tension. By subjecting a Sn wire coil to a uniform pressure in compressed He it was found that the line shifted to lower temps. For 300 kg./sq. cm. pressure a change of 0.005° was observed; this max. was reached practically for 193 kg./sq. cm. No change in the normal resistance curve occurred; the elastic limits were never reached. Similar results were obtained by compression of pure indium wires. For a pressure of 200 kg./sq. cm. the leap-point changes over -0.006° (it lies at 3.4° K.). These results seem to indicate that a relatively large space between the atoms is favorable for superconduction.

B. J. C. VAN DER HOEVEN

The measurement of single boundary potentials. EMIL BAUR. *Z. Elektrochem.* **31**, 514-7(1925); cf. Wild, *C. A.* **17**, 920; Buchi, *C. A.* **19**, 1222. According to Buchi, a sufficient condition for elimination of diffusion potential is that the 2 solns have equal cond. The cond. of AmOH solns. in distribution equil with N and 0.1 N KCl, N and 0.1 N CaCl₂ and 0.1 N HCl aq. solns. are, resp., 6.4, 1.9, 1.7, 0.37 and 23×10^{-6} mhos. The e. m. fs. of the chains: $\text{Hg} | \text{HgCl} | N \text{ KCl(aq.)} \rightleftharpoons N \text{ KCl(AmOH)} | N \text{ CaCl}_2(\text{AmOH}) \rightleftharpoons N \text{ CaCl}_2(\text{aq.}) | \text{HgCl} | \text{Hg}$ and a similar one using 0.1 N solns. instead of N are 0.026 and 0.022 v., resp. Those of the corresponding chains where an equiv. HCl soln., in equil. with AmOH, is inserted between the middle boundary (d) are 0.0015 and 0.0012. Thus the phase boundary potential, g , may be said to be 0.

D. S. VILLARS

Potential of fluorine as determined by measurement of the decomposition potentials of molten fluorides. BERNHARD NEUMANN AND HELMUT RICHTER. *Z. Elektrochem.* **31**, 481-3(1925).—The previously described app. (cf. *C. A.* **19**, 3205) was used with a Pt crucible and graphite electrodes. The av. potential (referred to H₂ as zero) of the F electrode in molten fluorides was extrapolated to 18° and is $1.923 \pm .01$ v. A direct measurement of the H₂F₂ decompn. potential in acid KF gave 1.9285 v. The potential of the Al electrode extrapolated to 18° was 0.844 ± 0.015 v. The negative temp. coeff. observed for chlorides, bromides and iodides is almost the same but that observed for fluorides is much more negative. Heats of formation calcd. from the temp. coeff. agree as well as could be expected with calorimetric data. D. S. VILLARS

Current-electromotive force curves for nickel and aluminium. E. LIEBREICH AND W. WIEDERHOLZ. *Z. Elektrochem.* **31**, 6-15(1925).—Current-e. m. f. curves have been detd. for Ni in 0.1% H₂SO₄, 1% H₂O₂ + H₂SO₄, 0.1% H₂SO₃, and 2 N NaOH, and for Al in 0.1 N NaOH, 0.1 N HCl and 0.1% H₂SO₄. The small Ni or Al wire was first made the cathode and the e. m. f. increased to vigorous H₂ evolution; readings of current and e. m. f. were then taken as the latter was decreased to 0, reversed, increased to complete anodic polarization, and finally back again to cathodic polarization. Curves plentifully annotated as to miscellaneous points of H₂ evolution, etc., are given for each of the above electrolytes.

WM. B. PLUMMER

Studies of electrolytic polarization. III. The diffusion layer. SAMUEL GLASSSTONE. *J. Chem. Soc.* **127**, 1824-31(1925).—"An examn. of the difference between the direct and the extrapolated overvoltages at Pb and Hg cathodes in various electro-

lytes has lead to the conclusion that the thickness of the diffusion layer at an electrode from which gas is being liberated freely decreases as the c. d. is increased; this is probably due to the stirring caused by the rapid evolution of bubbles. This view has been confirmed by an analysis of the abnormal fall in the back e. m. f. of a Hg cathode in a dil. soln. of H_2SO_4 contg. an excess of alkali sulfate, and of various cathodes in N HCl satd. with Cl. In previous work it has been found that O diffusing from the anode may influence the initial fall of the back e. m. f. of a Hg cathode in a manner which depends on the material of the electrode vessel and the c. d.; a similar abnormality has been observed as the result of the diffusion of anodic Cl toward a Hg cathode in HCl soln." R. H. LOMBARD

Researches on the paramagnetic salts. MME. E. COTTON-FEYTIS. *Ann. chim.* 4, 9-78(1925).—A monograph giving in full the results of elaborate investigations extending over a number of years, and correlating data published in earlier preliminary notes in *Compt. rend.* (1911, 1913), etc. The coeff. of magnetization was measured for a no. of salts in the solid state. The results are interpreted as indicating that in the case of certain ions dissociation begins in the crystal. It was found possible to detect certain reactions by magnetic measurements and also to distinguish between water of crystn. and "water of constitution". W. W. STIFLER

Doubly refractive white phosphorus. D. VORLÄNDER, WERNER SELKE AND GEORG KREISS. *Ber.* 58, 1802-6(1925).—The change of regular white P to the strongly doubly refractive variety was observed through the polarization microscope. On heating, the change occurred at -68° , and at -75° on cooling. P crystd. from CS_2 at -80° , and from ether at -100° gave 6-sided crystals, similar to those of K_2PtCl_6 . Neither As, the diamond, Au, NaCl, nor KI gave a similar doubly refractive product at the temp. of liquid O. The expts. will be continued with the use of liquid H. R. C.

The geometrical solution of color mixture problems. J. GUILD. *Trans. Opt. Soc. (British)* 26, No. 3, 139-75(1924-5). D. E. SHARP

The anomalous electrical double refraction of sodium vapor. R. LADENBURG AND H. KOPFERMANN. *Sitzb. preuss. Akad. Wissenschaften* 420-4(1925).—In a strong elec. field, the D-line of Na is displaced a little toward the red (0.01-0.02 Å. U.). The D_2 -line is polarized by an elec. field and the π -component, parallel to the field, is displaced more than the σ -component. The D_1 -line shows no difference in both polarizing directions. Using crossed Nicols with quarter-wave-length plates and inserting a field of 30,000 v./cm., the phase difference of the π - and σ -components is 6 arc degrees or $n_\pi - n_\sigma = 3.5 \times 10^{-7}$. Using half-shadow apparatus, $\lambda_\pi^0 - \lambda_\sigma^0$ is about 9/10 of the simultaneous displacement $\lambda_\pi^0 - \lambda_\sigma^0$, so that the π -component is displaced about 10 times as much as the σ -component. Analysis shows that the π -component should be made up of 2 components, the π_1 -component which is displaced as strongly as the π -component and is about $1/3$ as intense as the π_2 -component which is not displaced. MARIE FARNSWORTH

The spectral pyrometry of glowing bodies. HERMANN SCHMIDT. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch. Dusseldorf.* 6, 61-9(1925).—A mathematical paper which shows that the comparison of the intensity and color of the rays of an optical radiator with the rays of a black body leads to a varying definition of the temp. S . $S_m < T < S_F$, where S_m is the temp. of the monochromatic rays, T is the temp. of the radiator and S_F is the color temp. A higher and lower limit for T cannot be detd. from the spectral position of the energy max. in union with the Wien displacement law and the analogous law for bright Pt. T cannot be detd. from the intersection point of the logarithmic isochromatic lines so long as their absorption behavior in dependence on wave length is unknown; temp. detn. from the position of the ray I_{max} is somewhat successful. S_F is detd. from the intersection of the isochromatic lines; and in case the color temp. is independent of the wave length, by the position of the ray max. M. F.

The production of optical activity in silver by circularly polarized light. H. ZOCHER AND K. COPER. *Sitzb. preuss. Akad. Wissenschaften* 426-31(1925).—Circular optical asymmetry is produced in AgCl by irradiation with circularly polarized light; this asymmetry consists in an optical activity or differential refraction of different circular lights, recognized by a rotation of the vibration direction or polarization plane as a circular dichroism or Cotton effect. In the expts. a Ag mirror was converted into AgCl, and very fine Ag was pptd. from this by the action of light, the effect observed being due to the presence of this Ag. G. L. CLARK

The scattering of light by liquid boundaries and its relation to surface tension. III. C. V. RAMAN AND L. A. RAMDAS. *Proc. Roy. Soc. (London)* 109A, 272-9(1925); cf. C. A. 19, 3059, 3208.—The observations on the surface-scattering of light by clean

water and comparisons of its brightness (visual) with those of 28 other liquids indicate that the intensity of surface opalescence increases with decreasing surface tension or increasing values of n . Introduction of traces of oleic acid, etc., markedly increase the intensity as would be expected from the formation of a thin film of lower surface tension. Similarly the intensity of surface opalescence of liquid CO_2 increases as the crit. pt. is approached, although the directions of max. brightness are more nearly parallel to the surface than is ordinarily the case, and the polarization of the scattered light is only complete in the immediate vicinity of the regularly reflected rays. Similar observations have also been made of the interfacial scattering by the boundaries between CS_2 and MeOH mixts., as the crit. soln. temp. is approached.

Influence of radiation on ionization equilibrium. J. WOLTJER, JR. *Nature* 115, 534(1925).—Results obtained by Saha and Sve for their theory of the stationary state (cf. *C. A.* 19, 1811) may be obtained by starting from Einstein's paper on Planck's radiation law and from Milne's extension to the photo-elec. effect. This alternative method is based on the formulation of the conditions required, for a stationary state by means of probability laws governing the elementary processes involved.

FLORENCE N. SCHOTT

Scattering of α -particles by atomic nuclei and the law of force. E. RUTHERFORD. *Phil. Mag.* 50, 889-913(1925).—Previous expts. of R. and his collaborators have shown that the close approach of α -particles to heavy atoms like U follows the inverse-square law of force, but that the approach to light atoms like Mg and Al departs from the law and indicates a combination of both repulsive and attractive forces on penetrating into the light nuclei. The present expts. with Au, Mg and Al further demonstrate the same principles. With Au no departure from the inverse-square law is observed, but with Al and Mg, a great drop in scattering is observed in passing from the low velocity toward the higher velocity particles. A min. value is attained and the still swifter particles again show increased scattering. These minima seem to require the assumption of both attractive and repulsive forces, and R. tentatively assumes 3 shells, the middle one being negative and the outermost and innermost ones positive. Out-

side all, the inverse square law is obeyed. Between the first positive and negative, the repulsive force diminishes, so that a particle with sufficient velocity to reach this zone produces less scattering. Inside the negative shell the repulsive force (and scattering) again increases. The equiv. voltage for which this minimum occurs is about 3 million v. or about the same as that necessary to cause the ejection of a proton emission of a swift H particle. This indicates that such emission does not take place until the α -particle actually penetrates the satellite system. This min. scattering for both Al and Mg corresponds to a distance of approach of about 7.8×10^{-13} cm. S. C. LIND

A method of analyzing radioactive radiation by means of absorption. MME. J. S. LATTES *Compt. rend.* **180**, 1400-2(1925).—The technic (giving results already reported; cf. C. A. **19**, 1986 and *Compt. rend.* **176**, 867, 963; **177**, 798) consists in interposing a "radiator" or screen of fixed thickness and various absorbing "analyzing screens" within the series—radiating source, electromagnet and ionizing chamber. The radiator absorbs the primary β -radiation completely but emits secondary β - and γ -radiation. Five groupings of app. give the intensities of primary β - and γ -radiation of desired groups of rays. L.'s experience has shown that to each definite group of primary γ -rays there corresponds a definite group of secondary β -rays. A mathematical derivation of the intensity of the latter for any thickness of screen is given in detail. In all of L.'s work secondary γ -radiation produced by primary β -radiation has been less than the exptl. error C. M. BOUTON

The decay constant of radium-argon. MARIETTA BLAU. *Sitzb. Akad. Wiss. Wien Abt. IIa*, **133**, 17-22(1924).—New detns. of the decay const. of Ra-A give $\lambda_A = 0.2273 \pm 0.0007$ min.⁻¹ $T_A = 3.05 \pm 0.009$ min. where T_A is the half life of Ra-A. These values are in good agreement with those of Rutherford and Robinson. D. C. BARDWELL

Theory of the number of β -rays associated with scattered X-rays. G. E. M. JAUNCEY AND O. K. DEFOE. *Phys. Rev.* **26**, 433-51(1925)—A correction factor applied to the ratio of the scattering coeff. to the absorption coeff. brings the theoretical value of the ratio of the recoil to photoelectron tracks to 0.097 as against an exptl. value of 0.10 (cf. Compton and Simon, C. A. **19**, 1534). D. C. BARDWELL

Some properties of monatomic hydrogen. HERMANN SENFTLEBEN. *Z. Physik* **33**, 871-8(1925).—Monatomic H was produced by illuminating a mixt. of H₂ and Hg vapor with light of $\lambda = 2537$ Å. U. H is produced by collisions of the second kind between excited Hg atoms and H₂ mols. and the H atoms conduct heat from an electrically heated wire more rapidly than the H₂ mols., as is to be expected. An anomalous effect in the conduction of heat from the wire was noticed and traced to a poisoning effect of the surface of the wire by O. S. measured the absorption of light by the gas and on the assumption that each quantum produced 2 atoms of H the rate of atomization was secured, and at "equilibrium" this is the rate of recombination. From this and measurements of the heat cond. of the non-illuminated and illuminated gas a value for the velocity const. of recombination was secured. The mean life of H is found to be about $1/4$ sec., agreeing well with other observations. H. C. U.

The significance of the magnetism of the rare earths to atomic theory. F. HUND. *Z. Physik* **33**, 855-9(1925).—Using the methods of a preceding paper (cf. above) H. has assigned the electrons of the 4_f shell of the rare earths and calcd. the magnetic moments of their ions. The 4_f shell is filled beginning with Ce⁺⁺⁺ and ending with Eu⁺⁺⁺. The 4_u shell is filled from Gd⁺⁺⁺ to Cp⁺⁺⁺. The calcd. values for the magnetic moments agree remarkably well with the observed values except in the case of Eu⁺⁺⁺. This element usually contains Gd as an impurity and this may account for the discrepancy. A table is given of the predicted ground terms of the neutral atoms. A similar calcn. of the magnetic moments of the ions of the elements from Sc to Zn was unsuccessful. H. C. U.

The problem of the relativity fine structure. GREGOR WENTZEL. *Z. Physik* **33**, 849-54(1925).—Three postulates in regard to a modified perturbation theory for at. systems are discussed with reference to the relativity fine structure. The original should be consulted since a brief abstract is impossible. One of these postulates is practically identical with the theory of Heisenberg (C. A. **19**, 3064). H. C. U.

The capture and loss of electrons by α -particles. G. H. HENDERSON. *Proc. Roy. Soc. (London)* **109A**, 157-65(1925); cf. C. A. **17**, 1375.—By the use of an ionization method the ratio of He⁺⁺/He⁺ was found to be independent of the nature of the material through which the rays pass, contrary to the prediction of Fowler (C. A. **18**, 1237). This ratio varies with the velocity raised to a power n which, however, decreases as the velocity increases; $n = 6.4 - 4.2 V/V_0$ approx. The results agree with those obtained by Rutherford (C. A. **18**, 1081) using the scintillation method. F. O. ANDEREGG

The absorption and scattering of γ -rays. N. AHMAD. *Proc. Roy. Soc. (London)* **109A**, 206-23(1925); cf. *C. A.* **18**, 2105, 3312.—The absorption of γ -rays from Ra B and C obeys the same general laws of absorption as do ordinary X-rays. The results agree well with Compton's formula; but are only from 0.2 to 0.33 as great as predicted by the classical theory. F. O. A.

The industry of radioactive compounds. CAMILLE MATIGNON AND (MISS) G. MARCHAL. *Chimie et industrie* **14**, 343-57(1925).—Brief historical review of its development, with a description of the more important radioactive minerals, their treatment for the extn. of Ra, and the applications of the latter. A. PAPINEAU-COUTURE

The occurrence of helium and neon in vacuum tubes. R. W. RIDING AND E. C. C. BALY. *Proc. Roy. Soc. (London)* **109A**, 186-93(1925).—The results of Collie, Patterson and Masson (*C. A.* **9**, 20) have been confirmed by bombarding nitrides of Al or Mg with cathode rays. He, Ne and H are set free but are usually occluded by spluttered metal. On strong heating they are set free. The H and He seem to be formed by the disintegration of N, the He in such a highly active condition as to allow synthesis of Ne. Of 2 induction coils tried only the smaller, which gave a 6" spark, produced results. F. O. ANDEREGG

The chemical activity of helium. E. H. BOOMER. *Proc. Roy. Soc. (London)* **109A**, 198-205(1925); cf. *C. A.* **19**, 753.—Expts. with intense electronic discharge from a W filament in low-pressure He led to the belief of a stable WHe_2 being formed. At a pressure of 0.1 to 0.45 mm. the rate of disappearance of He was greatest, reaching 5 cu. mm./min. at 1000 v. The loss in W was detd. by weighing the filament. The presence of Hg reduces the amt. of this compd. formed, although it increases the evapn. of W. The He is liberated on heating the spluttered material on the wall above the softening point of the glass or by treating with 20% HNO_3 or KOH. Any W present as compd. was dissolved by KOH but excess metallic W was not affected. Mixts of He, H and N gave only negative results. F. O. ANDEREGG

The chemical action of gaseous ions produced by α -particles. VI. Reactions of the oxides of carbon. S. C. LIND AND D. C. BARDWELL. *J. Am. Chem. Soc.* **47**, 2675-97(1925); cf. *C. A.* **18**, 3139.—With radon as a source of ionization, the reactions thereby produced in the following gases and gaseous mixts. were studied: CO, CO + O₂, CO₂, CO + H₂, CO₂ + H₂. A comparison is made between the no. of mols. reacting and the no. of ion pairs generated in the reactants, and the ratio is in all cases except CO₂ a large fraction of or a small multiple of unity. An ionic mechanism is proposed for several of the reactions. D. C. BARDWELL

Predicted ionization-potentials of niton and hydrofluoric acid. GEORGE GLOCKLER. *Phil. Mag.* **50**, 997-1001(1925).—On the basis of a rule relating quantum defect and at. no. Turner (*C. A.* **19**, 435) predicted a value for the ionization potential of Rn of 27.5 ± 1.5 v., which is higher than that of the lower members of the noble gases. In general, ionization potentials are higher for the lower members of a series and accordingly from He, Ne, etc., G. predicts a value for Rn of 10 ± 0.9 v. and of 15.7 ± 0.7 v. for HF. The kinetic theory radius of Ne is estd. from Eve's rule to be 1.29 A. U. and of Rd 2.8 ± 0.25 A. U. S. C. LIND

Contributions to the knowledge of atmospheric electricity. LXV. The characteristics of current in weakly ionized gases. EGON SCHWEIDLER. *Sitzb. Akad. Wiss. Wien Abt. IIa*, **133**, 23-7(1924).—If a weakly ionized gas contains adsorption kernels, which can form heavy ions, the rate of ion recombination is shown mathematically to be proportional to the ion concn. Formulas are developed showing the proportionality between the cond. of a weakly ionized gas and the satn. deficit. "Half potential" is defined as that potential at which the current at the electrodes of a condenser is half the satn. current. The application of these conceptions to the study of atm. electricity is discussed. LXVI. **Experimental studies on the characteristics of current in a weakly ionized gas.** WALTER SCHLENCK. *Ibid* 29-33.—It is found that the rate of recombination of ions in a weakly ionized gas is proportional to the ion concn. and that the proportionality factor is dependent upon the concn. of dust particles present. D. C. BARDWELL

The mobility of argon and hydrogen ions in air. H. A. ERIKSON. *Phys. Rev.* **26**, 465-8(1925); cf. *C. A.* **19**, 437.—By methods previously described, 2 positive ions and 1 negative ion were found for A and H₂ as in the case for air. The initial H ion was found to transform into the second. The following mol. ions have the same mobility in air at normal pressure: monatomic A, initial + and -; diatomic air, initial + and -; diatomic H₂, initial +; and triatomic CO₂, initial + and -. Thus the mobility of these ions seems to be independent of the masse. Initial H₂⁻ has higher mobility. D. C. BARDWELL

Probability of ionization of gas molecules by electron impact. K. T. COMPTON AND C. C. VAN VOORHIS. *Phys. Rev.* **26**, 436-53(1925).—Measurements are made from which the no. of ions per cm. of path produced by an electron moving through a gas at 1 mm. pressure are calcd. for: H_2 , He, Ne, A, N_2 , Hg and HCl. In each case there is a voltage at which the no. goes through a max. The probability of ionization upon collision is calcd. for the max. conditions, assuming kinetic-theory values for electronic mean free path. The results are summarized and compared with previous results.

D. C. BARDWELL

The excitation of the O-energy levels in tungsten by electron bombardment. OTTO STUHLMAN, JR. *J. Elisha Mitchell Sci. Soc.* **41**, 20(1925).—When thermoelectrons liberated from a W filament were accelerated and allowed to impinge on a W grid, secondary electrons were emitted by the grid. The no. emitted were measured by means of a galvanometer in series with the grid and a plate maintained at a const. positive satn. potential. The O-energy levels so far discovered have n/R values as follows: $O_2-O_1 = 0.608$, $O_4-O_3 = 2.96$ and $O_5 = 5.20$.

A. L. MEHRING

The migration of ions in solid electrolytes. II. M. LE BLANC AND M. KRÖGER. *Z. Elektrochem.* **31**, 359-60(1925); cf. *C. A.* **18**, 3516. —A reply to the article of Tubandt and Reinhold (*C. A.* **19**, 1520).

D. C. BARDWELL

The effect of light upon the thermal conductivity of selenium. R. E. MARTIN. *Phys. Rev.* **26**, 475-85(1925).—Evidence is given which indicates that the thermal and electrical cond. in metals depends to a considerable extent upon the same factors.

D. C. BARDWELL

Thermoelectric effect in single-crystal zinc wires. E. G. LINDER. *Phys. Rev.* **26**, 486-90(1925).

D. C. BARDWELL

The J phenomenon in X-rays. II. Application to scattered X-rays. C. G. BARKLA AND S. R. KHASTGIR. *Phil. Mag.* **50**, 1115-34(1925); cf. *C. A.* **19**, 2450. —The nature of the X-radiation scattered by paper has been examd. by means of its absorption. The scattered radiation either has definitely the same absorption as the primary, or else differs markedly from it. The change is not a Compton effect and yet it is connected with it in some way. When a change of wave length occurs the J discontinuities are the steps from one level to another and the change of activity is the J transformation. The dependence on some unknown crit. condition is characteristic of the phenomenon.

S. C. L.

Magnetic quality in crystals. J. FORREST. *Phil. Mag.* **50**, 1009-18(1925).—An attempt is made to establish magnetic crystal lattices and to compare them with the X-ray lattices in different crystal systems.

S. C. L.

Reflection of X-rays from potassium bromide crystals. HELMUTH KULENKAMPFF. *Physik. Z.* **26**, 657-8(1925).—Clark and Duane (*C. A.* **16**, 4134; **17**, 2230, 2660; **18**, 346, 3316) reported anomalous reflection of X-rays from alk. halide crystals, attributing the phenomenon to the excitation of the K series of some of the constituents of the crystals. Recently, Armstrong, Duane and Havighurst (*C. A.* **19**, 1817) obtained only normal reflections from well-formed crystals of KI and CsI. Walter (*C. A.* **18**, 1430) and Mic (*C. A.* **17**, 2820; **18**, 18) were unable to confirm the anomalous reflection. K. presents further evidence for the nonexistence of the phenomenon.

F. C. KRACEK

Total intensity of scattered X-radiation. O. K. DEFOE AND W. W. NIPPER. *Nature* **115**, 607(1925).—A Coolidge tube with a Mo target, which was operated at about 5 ma. and 25 kv. peak was used in a room about 22 × 25 ft. and 10 ft. high. It was located about 2 ft. from one side and equidistant from the ends of the room. The effect of the radiation on a photographic film placed about 50 cm. from the tube, and on a fluoroscope indicates that the intensity of the scattered radiation inside the room is nearly of the same order as that of the direct radiation (cf. *C. A.* **19**, 210).

FLORENCE N. SCHOTT

Spectroscopic evidence of J-transformation of X-rays. S. R. KHASTGIR AND W. H. WATSON. *Nature* **115**, 604-5(1925).—Attention is directed to irregularities occurring in the relation between the at. no. of a radiator and the wave lengths of its X-ray emission spectrum of K-series. At $n = 52$ and 56 there is an increase in wave lengths K_{α_1} of about 0.01 A. U. in each case. These irregularities also occur in K_{α_2} and K_{β} but not in K_{α} . The wave lengths at which these sudden increases take place correspond very well with 2 of the crit. absorbabilities for J-transformation, which with Al are $(\mu/\rho)_{Al} = 1.9$ and 0.7 (cf. *C. A.* **12**, 20, 2279). Conclusion: These irregularities are due to the J-transformation of X-radiation taking place in the calcite crystal used for the analysis of the radiation or possibly in the anticathode or walls of the X-ray tube. This suggests the view (cf. *C. A.* **18**, 623; **19**, 932, 1093, 2450) that the apparent

increase of wave length as observed by Compton and others in the scattered radiation is due to the same J-transformation during transformation in the crystal or in the radiator, and is not part of the phenomenon of scattering. FLORENCE N. SCHOTT

The Compton and Duane effects. G. E. M. JAUNCEY. *Nature* 115, 456-7 (1925).—The excess variation in the long wave-length limit of the modified band is explained by taking into account the momentum of the scattering electrons in their Bohr orbits. With a large variation of ϕ the intensity would be greatest at the short wave-length limit of the band as observed by Duane with a large scattering block. However, Compton, using a smaller scattering block and a spectrometer of less resolving power than Duane, finds for $\phi = 90^\circ$ that the wave-length change of the most intense part of the modified band is 0.0242 A. U. For a large scatterer the intense portion becomes indistinct and hence tends to obscure the existence of the Compton wave-length change. A spectrometer of low resolving power will show the Compton wave-length change better than one of high resolving power.

FLORENCE N. SCHOTT

A note on the summation rules for the intensities of spectral lines. R. H. FOWLER. *Phil. Mag.* 50, 1079-83 (1925); cf. *C. A.* 19, 2600.—It is the object of this note to give as accurate theoretical interpretation as possible of the well-known summation rules of Ornstein, Burger and Dorgelo by a refined application of the correspondence principle, in order to see in what sense the summation rules are to be interpreted when applied to associated lines whose frequency differences are not entirely negligible. It is shown that if the intensities are reckoned in nos. of quanta per sec., then the summation rules ought to be fulfilled to the degree of accuracy with which the Fourier coeffs. of the original electronic system are left unaltered by the superposed perturbation which splits the radiation up into the associated group of lines.

S. C. L.

Experiments on the absorption of the Balmer lines in hydrogen. RUBY V. JOLOWICZ. *Phil. Mag.* 50, 1089-96 (1925).—An attempt is made to absorb lines of the Balmer series of H, by passing them through H being excited by bombardment of thermoelectrons propelled at suitable voltages. The negative result is taken to mean that but few excited H atoms were present and the ions known to be present were of the mol. type H_2^+ which are produced at about 16 v.

S. C. L.

Fine structure of spectrum lines. A. E. RUARK AND R. L. CHENAULT. *Phil. Mag.* 50, 937-56 (1925).—After a general consideration of the facts of fine structure lines, the treatment is confined to the case where several components arise from one spectral level all characterized by the same total, azimuthal and inner nos. A table shows the character of spectral levels for 21 elements and the fine structures of Al, Cd, Tl, Cu, Pb, Bi, Mn, Br and I. The spectral classifications of Mn are effected by the aid of fine structure and some predicted lines have been found.

S. C. L.

The molecular structure and infra-red spectrum of methane. D. M. DENNISON. *Astrophys. J.* 62, 84-103 (1925).—An attempt is made to treat the CH_4 mol. by the quantum theory and to det. the frequencies which it may absorb or emit. The assumption is made that in the normal state the 4H nuclei lie at the corners of a regular tetrahedron while the C nucleus lies at the center, and that, following an infinitesimal displacement of the nuclei the potential energy depends on the squares of the displacements along the lines between the nuclei. This model yields 4 normal frequencies, which through the use of two undetd. constns. may be made to coincide closely with the 4 fundamental frequencies found exptly. by Cooley (cf. following abstract). By studying the change of the electric moment the relative intensities of these 4 bands are predicted in satisfactory agreement with the exptl. intensities. W. F. MEGGERS

The infra-red absorption bands of methane. J. P. COOLEY. *Astrophys. J.* 62, 73-83 (1925).—Previous investigations on CH_4 with prism spectrometers have shown 3 absorptions bands at 7.7μ , 3.31μ and 2.35μ . By using diffraction gratings with 2800 or 7200 lines per inch these bands have been partially resolved into lines. Hollow brass cylinders, $1/2$ mm. to 30 cm. in length with thin sheets of mica for ends, were used as containers for the gas; the source of light was a Nernst glower; the detecting system consisted of thermopile and galvanometer. About 50 lines in the region 3.31μ were measured and arranged in positive and negative series. Between these and masking part of the negative or longer wave-length series, lies a narrow region of intense absorption corresponding to the zero branch. The band at 7.7μ is similar to the one at 3.31μ . Twelve lines in the negative series and 18 in the positive series have been measured but again in the zero branch no fine structure appears. The resolving power of the app. was insufficient to show much detail in the band at 2.35μ . In the positive and negative branches near 7.7μ the frequency difference between adjacent lines is 77 cm^{-1} , and near 3.31μ it is 5.41 cm^{-1} . A fair band of 12 lines near 3.5μ has a frequency difference about 15.3 cm^{-1} . Corresponding to these 3 frequency differences

the moments of inertia of the CH_4 mol. are 5.66×10^{-40} , 10.2×10^{-40} and 3.61×10^{-40} g sq. cm.

W. F. MEGGERS

The red neon lines. KEVIN BURNS. *J. Optical Soc. Am.* **11**, 301-10(1925).—The relative values for the wave lengths of some 20 lines in the Ne spectrum are tested with the interferometer and with const. differences in wave nos.; the values of these standards are sufficiently accurate to justify taking the means to 4 places of decimals in A. U.

W. F. MEGGERS

The auroral green line. J. C. McLENNAN. *Nature* **115**, 382(1925); cf. *C. A.* **19**, 2782.—The line $\lambda 5577.35 \pm 0.15$, thought to be identical with the auroral green line, is observed in the spectrum of a mixt. of air and an excess of He. The line was not observable in the spectrum of purified O, H, N or He. No mixts. of any 2 of these gases other than O and He gave this spectral line. *Ibid* 607.—The line $\lambda 5577$, which McL. thinks is identical with the auroral green line, can be obtained with a mixt. of O_2 and excess of He at room temp. with suitable pressure. This line probably has its origin in O.

FLORENCE N. SCHOTT

The resonance radiation from thallium vapor. A. L. NARAYAN AND K. RANGAD-NAMA RAO. *Nature* **115**, 534(1925).—N. and R. confirm previous exptl. results showing that $1\pi_2$ is the ground orbit of the valence electron in the Tl atom. Tl vapor, subjected to radiation $\lambda 5350$ ($1\pi_1 - 1\sigma$), does not emit any radiation, while when illuminated by radiation $\lambda 3775$ ($1\pi_2 - 1\sigma$) it acquires the ability of emitting radiation $\lambda 5350$ and 3775, the fluorescent track in this latter case being of a beautiful green color.

FLORENCE N. SCHOTT

The spectrum of potassium excited during its spontaneous combination with chlorine. L. A. RAMDAS. *Nature* **115**, 533-4(1925).—The spectrum emitted by K burning in Cl at normal pressure spontaneously was photographed with the quartz spectrograph. A very strong emission band in the red is shown extending from about 7200 to 6150, corresponding to the emission and absorption bands obtained by McLennan and Ainslie in the fluorescence and absorption spectra, resp., of dense K vapor. Many are lines of moderate intensity and the enhanced lines are seen: 4466, 4388, 4307, 4220 and 4115. Since no external elec. forces were used these enhanced lines are excited by the electron affinity of the Cl atom, together with the temp. attained by the K vapor as a result of the chem. reaction.

FLORENCE N. SCHOTT

Intensities of band spectrum lines. H. HÖNL AND F. LONDON. *Naturwissenschaften* **13**, 756(1925).—Preliminary report on a new calcn. method (cf. Fowler, *C. A.* **19**, 2600). Publication in *Z. Physik* will follow.

B. J. C. VAN DER HOEVEN

The structure of the mercury line 2536 A. U. R. W. WOOD. *Nature* **115**, 461(1925); cf. *C. A.* **20**, 17.—The structure of the Hg line 2536 A. U. photographed by Nagaoka is not the true structure, caused by the absorption of the Hg vapor in the neck of the Arous lamp, which is in a state of ionization from its contact with the arc. The true structure, observed with a water-cooled vertical quartz Hg arc, has 5 components of uniform intensity; 4 are at sensibly equal intervals; the fifth is at a slightly greater septn.

FLORENCE N. SCHOTT

The doublet structure of a class of band spectra. R. MECKE. *Naturwissenschaften* **13**, 755-6(1925).—According to Landé the width $\Delta\nu$ of doublet terms for alk. metals and some other elements is proportional to Z^2/n_a^3 ($Z_s = Z - s$ is the effective at. no.; s is the screening coeff. averaging 4; n_a is the effective main quantum no.). This rule is applied to those compds. which are comparable to alk. metals in that 1 valence electron is free to emit a (band) spectrum: CN , BO , C^+O , N_2^+ , also singly ionized alk. earth halides. For the latter it is empirically found that the ratio of the doublet widths for CaCl^+/K , SrBr^+/Rb and BaI^+/Cs is practically const. and equal to 1.35. Assuming for this reason that the width is proportional to $1/2(Z_s^2 + Z^2)$ for the halides, M. proceeds to calc. approx. values of Z_s for the halogens and for the alk. earths; n_a varies for the 9 (ionized) alk. earth halides from 2.11 to 2.23 (n_a for K, Rb and Cs runs from 2.23 to 2.34). It appears that the light electron obtains its doublet energy by penetrating into the L levels of both the constituent atoms. For fluorides similar results were obtained with the only difference that the entire doublet energy is derived from the alk. earth atom ($\Delta\nu \sim Z_s^2$); n_a for MgF^+ , CaF^+ and SrF^+ is 2.28.

B. J. C. VAN DER HOEVEN

The specific lines of the arc spectrum. A. T. WILLIAMS. *Anales soc. argent. Argentina* **99**, 13-84(1925).—A careful analysis of the exptl. results of Kayser and Runge, Exner and Haschek, Huppers and others has led to the following conclusions. The arc spectrum presents characteristic lines absent from the spark spectrum. The hypothesis of their being caused by accidental impurities is disproved by the fact that they can be classified in series and that the structure of these spectra is similar for

elements of similar electronic structure and chem. properties. The lines not yet classified may be attributed to series corresponding to instable states of elements (ortho elements). This could serve as a basis for classification. The variations due to isotopes do not seem to influence the structure of the spectra. With a few exceptions the principle of selection applies strictly to all lines of class A. Whenever there is an exception, the spectrum always contains combination lines of the same class; for these lines the variation of the azimuthal quantum nos. is 0. The intensity of the arc lines is in harmony with Bohr's theory. The relation A/C (A no. of arc lines, C no. of spark lines) varies periodically with the at. no., the minima occurring at the end of each period. A/C is always 0 for the halogens. The curve representing this relation ought to be the reverse of the one representing the variation of ionization potentials, as soon as the latter can be established from data relative to the structure of spectra. A factor of influence on the structure of spectra is the no. of electron, situated in the orbit adjacent to the optical electron shell. The result is periodicity of certain spectral consts within each column of the periodic system. This relation is intimately connected with the conception of the actual charge of the nucleus, which is detd. by the screen effect produced by the electrons situated between the nucleus and the outer orbit.

MARY JACOBSEN

Absorption spectra of morphine solutions in the ultra-violet. LUIS A. BONTEMPI. *Anales soc. cient. Argentina* 99, 209-28(1925).—A morphine-HCl soln shows on addn of NaOH a displacement of the absorption toward the red. The displacement reaches its max. when 1 equiv. NaOH is added, and is not affected by excess NaOH. Since morphine isolated in crystals (by addn. of NaOH to the HCl salt) has the same spectrum it is concluded that the latter is characteristic for the free base, that the displacement is due to some rearrangement taking place in the moment of its liberation and that HCl has no influence on the spectrum. The tertiary phenol group is made responsible for the displacement, since the same phenomenon was observed in phenols. A more intimate interpretation may be gained by means of the quinonoid theory of Hantzsch, the residual affinity of Baly or the electronic valence theory of Stark. The keto-enol equil. does not lend itself to the explanation.

MARY JACOBSEN

The absorption spectrum of aluminium. KANAKENDU MAJUMDER AND NALINE KANTA SWE. *Nature* 115, 459(1925).—Expts on the absorption spectrum of Al were made to det. whether the $2p$ orbit is the normal stage, as has been obtained from the analysis of its arc spectrum and corroborated by the absorption expts with In, Ga and Tl. The vacuum furnace designed by Saha for ionization work was used. No Al lines are obtained below 1500° . At 1520° the pair $\lambda = 3961, 3944$ come out reversed. At 1650° the leading members of $2p$ - md come out reversed. The higher members of $2p$ - ms series require a higher temp. The $2p$ - ms lines and $2p$ - md lines of Ga occur rather prominently, indicating its presence as an impurity in ordinary Al. The high temp. required to produce sufficient vapor for absorption work is sufficient to convert any lower ls orbit to the $2p$ orbits. If the $2p$ orbits are the normal orbits of Al atom, the $2p$ - mx lines do not dominate the spectrum to the same extent as the ls orbits of alkalis dominate their spectra.

F. N. S.

The energy-distribution law appropriate to the theory of chemical reaction velocity. C. N. HINSHELWOOD AND C. W. THORNTON. *Phil. Mag.* 50, 1135-9(1925).—The change of rate of bimol. reactions as a function of the temp. is again considered. The assumption is made that the energy increment may be contributed by addn. of the energies of both components, and the chance that the 2 mols. in collision shall have

$$-(E_1 + E_2),$$

the crit. energy will be $e^{-\frac{K_1}{RT}}$. Assuming the energy of activation to be entirely kinetic, a correct distribution law for energy of translation is developed and applied to the 3 bimol. decompns. Cl_2O , HI and N_2O . It was not possible to decide in this

way the form of the distribution law, and provisionally $e^{-\frac{E}{RT}}$ may be used. Unsuccessful efforts are also made to distinguish between the 3 forces of energy, translational, vibrational and rotational. All 3 may contribute to a state of activation. In general thermal quanta are small compared with heat of reaction, and the thermally activated state is built up by a no. of quanta.

S. C. L.

The critical increment of chemical reactions. W. E. GARNER. *Phil. Mag.* 50, 1031-3(1925).—Replying to Hinshelwood (*C. A.* 19, 3409) regarding the probability of reaction of activated mols. The effect of temp. on the probability factor is further discussed (cf. *C. A.* 19, 1819).

S. C. L.

The glow of phosphorus. H. J. EMELEUS. *Nature* 115, 460-1(1925).—The phenomena of the glow of P have been suggested as due to the slow oxidation of P_4O_6 .

formed in a preliminary non-luminous oxidation. A spectroscopic study of the nature of the light emitted from glowing P and that from the element burning normally gives the same spectrum. This is continuous in the visible region, and has five bands in the ultra-violet between $\lambda = 2370$ A. U. and $\lambda = 3290$ A. U. (cf. C. A. 19, 2452). The light from glowing P_2O_3 and from spontaneously inflammable PH_3 burning in O_2 gives this same spectrum. Hence these 2 oxidations are analogous but not necessarily identical chem. processes.

FLORENCE N. SCHOTT

4—ELECTROCHEMISTRY

COLIN G. FINK

Electric furnaces in 1925 (in Great Britain). W. S. GIFFORD. *Electrician* 95, 617-27(1925)—Two illus. A review with particular emphasis on the rapid development of the induction, low and high frequency, type of elec. furnace. C. G. F.

The electrothermic zinc industry. CANAUD. *Rev. métal.* 22, 571-80(1925)—A review of recent progress in the electrothermal metallurgy of Zn. A. P.-C

Recent progress in electrochemistry and electrometallurgy. L. ANDRIEUX AND R. FLUSIN. *Technique moderne* 17, 693-705(1925)—A review. A. P.-C.

Course of electrochemical reduction of solid electrodes. KURT FISCHBECK. *Z. anorg. allgem. Chem.* 148, 97-129(1925).—The purpose is to prove that the reduction to the metal of difficultly sol. metallic conducting compds. which are not attacked by acids or alkalis proceeds because the outer layer in contact with the electrolyte conducts the current electrolytically and the anions present in this layer are thereby enabled to pass off into the soln. A *coulometer* is described which instantly measures quantities of electricity as small as 10^{-3} coulombs. This is done by observing the vol. of H_2 evolved from a Pb cathode in a 2% H_2SO_4 soln. The reduction yield (%) of total current which is used to reduce the solid) of powders of SnO_2 , CuS , CuO , $FeCuS_2$, PbS or Sb_2S_3 on a platinized electrode are about 75, 100, 100, 35, 55 and 60%, resp. These vary with the current strength. A melted piece of AgI is reduced according to Faraday's law. This proves that the place of reduction is at the compd./electrolyte interface. When H_2 evolution accompanies the reduction of solid coherent electrodes, the amt. reduced is a linear function of the time. With decreasing c. d. the reduction yields of Sb_2S_3 and $FeCuS_2$ increase and approach 100%. The H_2 evolved on the dissoln. of the reduced Fe makes the reduction yield of FeS_2 approach an apparent limit of 50%. The reducing part of the current J_r may be expressed: $J_r = A \log(1 + B.J)$, where J is the total current and A and B are consts. The increase in p. d. of the electrode due to the current is: $\Delta E = RT/nF \ln(1 + B.J)$. J_r should therefore be a linear function of the p. d. and, to test this, reductions were made where J_r was the whole current (where there was no H_2 evolution). Ag electrodes covered with a layer 100-500 μ thick of a Ag compd. were used. For AgI, AgBr, AgCl and Ag_2S the current gradually decreases with time until the last trace of halide disappears when there is a sudden decrease to the value obtaining at an equil. between diffusion and discharge of H^+ . The no. of coulombs necessary for reduction were independent of the current strength. A smaller no. of coulombs were required for the thinner layers (100-400 μ) than were to be expected. This is because the detn. of the time of disappearance of the layer entails a larger exptl. error for the smaller layers. The p. d. current curve is independent of the thickness of the layer. For high c. ds. it is a straight line function. Such a curve for an electrode with no layer is logarithmic. For small c. ds. the p. d. decreases much more rapidly with decreasing current and the curve is continuous for negative currents (anodic polarization). The combination Ag/AgX (solid)/aq. electrolyte changes from electrolytic cond. (by Ag^+ ion in the AgX layer) for anodic and small cathodic polarization to metallic cond. for cathodic polarizations over 0.055, 0.009, 0.015, 0.018 v., for Ag_2S , AgI, AgBr and AgCl, resp. (potentials where Ag starts to sep. out at the contact layer of AgX/electrolyte). D. S. VILLARS

Plates base metal with nickel. J. D. KNOX. *Iron Trade Rev.* 77, 247-8(1925).—The resistance of steel to take a coating of Ni by the electrolytic process is overcome by eradicating the surface gases. In the *Madsen process*, anodes of 99.8% Ni are used. With a c. d. of 35 amps. per sq. ft., 0.002 in. of Ni is deposited per hr. 55° is the optimum temp.

Electrical gas purification. WALTHER DEUTSCH. *Z. tech. Physik* 6, 423-37(1925).—The following topics are discussed: (1) a survey of the industrial application, methods and history of the process; (2) the theory of the charge, migration velocity and the pptn. of dust; (3) the detector action effect of positive point discharge, and the dis-

J. F. BYRNE

turbance phenomena resulting from it. The following data are given: Radius of dust particle (cm.) 10^{-3} , 10^{-4} , 10^{-5} , 10^{-6} , 10^{-7} and 10^{-9} (ion). No. of elementary charges, 4640, 376, 28, 2, 1, 1. Migration velocity in a field, 1 (c. g. s.) cm./sec., 0.69, 0.56, 0.42, 0.35, 1.5, 450. A bibliography of 40 references is included. J. H. PERRY

Electric precipitation of dusts. A. DELASALLE. *Chimie et industrie, Special No.*, 134-7 (Sept., 1925).—Brief review of its development in the U. S. and in France.

A. PAPINEAU-COUTURE

Metal tank mercury arc rectifiers. F. D. NEWBURY. *Elec. J.* 22, 570 (1925). C. G. F.

New galvanizing process (ANON.) 9. The orientation of crystals in electrodeposited metals (BOZORTH) 2. Dimensional system of notation (PETROVSKY) 2. Tempering light alloys (U. S. pat. 1,562,269) 9.

Storage battery. W. E. GOSSLING. U. S. 1,562,159, Nov. 17. Structural features.

Wood separators for storage batteries. C. C. CARPENTER. U. S. 1,561,774, Nov. 17. After treatment of wood separators with NH_4OH the NH_3 is eliminated by boiling with H_2O contg. caustic lime.

Storage battery plates. C. C. CARPENTER. U. S. 1,561,775, Nov. 17. H_2SO_4 is applied to the face of storage battery plates and the plate surface is simultaneously subjected to a rolling pressure and subsequently dried by heating.

Electrolytic cell adapted for refining aluminium. W. HOOPES. U. S. 1,562,090, Nov. 17. The cell has a bottom lining of C with a tapping well extending below its surface.

Coating electrodes for vacuum tubes. J. E. HARRIS. U. S. 1,562,164, Nov. 17. An alk. earth oxide such as BaO and SrO is applied to a metal such as W, Fe, Ni or Mo, the oxide of which is combinable with alk. earth metal compds. to form compds. not reducible to alk. earth metal oxide by heating *in vacuo*. The coating with oxide is effected by prepg. an electrolyte composed of an alk. earth metal compd., e. g., Ba and Sr salts, placing a filament of the metal to be coated in the electrolyte and electrolytically depositing on the filament an alk. earth metal coating which is convertible, in part at least, to alk. earth metal oxide upon exposure to air.

Electrolytic production of floats or other hollow metal articles. C. C. CLELAND and J. C. MULLINIX. U. S. 1,560,017, Nov. 3. The deposition is made upon a partially immersed core which is intermittently reversed in the electrolyte.

Solutions of alkali metal silicate. L. W. CODD. U. S. 1,557,491, Oct. 13. An alkali silicate soln. is subjected to limited electrolysis without substantial sepn. of silica until a soln. is obtained in which the ratio of silica to soda is less than 15 to 1.

Electric arc furnace for melting metals. F. KOSTKA. U. S. 1,561,731, Nov. 17.

Electric furnace adapted for shaping plastic silica. L. B. MILLER. U. S. 1,562,115, Nov. 17. The furnace is arranged for extrusion of silica from a refractory container so as to form tubing or similar articles.

Electric resistance furnace adapted for heating buildings. J. SECHOWSKI. U. S. 1,562,261, Nov. 17.

Automatic control for electric furnace electrodes. R. CARLSTEDT. U. S. 1,562,204, Nov. 17.

Dielectric composition. BRITISH THOMSON-HOUSTON CO., LTD., and W. P. DAVEY. Brit. 232,920, April 22, 1924. A plate-spacing material for elec. condensers comprises a non-conducting material such as cellulose contg. a compd. of unsatd. fatty acids such as linseed oil, China wood oil or castor oil.

Apparatus for the electrodeposition of metals on wires and strips. J. A. PARKER. Can. 254,956, Oct. 27, 1925.

Nickel-plated articles. F. M. BECKET. U. S. 1,561,900, Nov. 17. Ni-plated articles are formed of ferrous metal alloyed with sufficient Cr (usually about 10-20% or more) to render the metal substantially non-rusting under atm. conditions.

Electroplating apparatus. J. M. GAUSS. U. S. 1,561,602, Nov. 17.

Tungsten wires. H. M. FERNBERGER. U. S. 1,558,000, Oct. 20. W filaments substantially free from sagging and off-setting are produced by dissolving WO_3 in an alk. soln. contg. K, Rb or Cs, e. g., a soln. of NH_4OH and K_2CO_3 , obtaining crystals of a double salt of K and W from the soln., and using these crystals for the production of W metal.

Electrodes for arc lamps. F. BAHR. U. S. 1,562,277, Nov. 17. Material of high electron emissivity is transferred from one electrode of an arc to another, e. g., from an

electrode formed of metal and Th oxide to one formed of W, by establishing an arc between the electrodes in a sealed container. This stabilizes the arc and facilitates starting.

5--PHOTOGRAPHY

C. E. K. MEES

Present status of sensitometric methods (for the examination of photographic emulsions). L. P. CLERC. *Chimie et industrie, Special No.*, 405-11 (Sept., 1925).—A review with bibliography of 27 references.

A strong intensifying process. G. ZELGER. *Chimie et industrie, Special No.*, 413 (Sept., 1925).—The bleaching soln. is made up of: (A) Cu sulfate 5 g., glacial AcOH 28 cc., H₂O 500 cc.; (B) NH₃ aq. (22° Bé.) 46 cc., KI 5 g., H₂O 250 cc.; mix A and B and cool before using. Immerse the well-washed negative in the bleaching soln. till yellow, wash for not less than 20-30 min., immerse in AgNO₃ soln. (2 g. in 750 cc. H₂O) till completely black, rinse, wash 1-2 min. in 1% NH₃ to remove sol. Ag on the gelatin, wash and dry. The operation may be repeated a 2nd and 3rd time, provided the negative is washed at least 30 min. each time; but the 3rd treatment has a tendency to cloud the whites. The process allows of using negatives which showed but a faint image. It can be used on cinematographic films, but washing must be prolonged (but not over 1 hr.) on account of impregnation of the wooden frames by the baths. Wooden or slate tanks should be used, and Pb linings avoided.

Infra-red photography by phosphorescence. A. A. GUNTZ. *Chimie et industrie, Special No.*, 414-5 (Sept., 1925).—Instead of ZnS with green phosphorescence due to a trace of Cu, G. uses ZnS with orange-yellow phosphorescence due to sensitization with a trace of Mn, which has the following properties: after insolation it rapidly loses part of its phosphorescent energy, but retains the remainder practically undiminished for several days, under the action of infra-red light, the residual phosphorescent energy reappears quite brilliantly. The photographic process is as follows: Insolate the ZnS film, make the infra-red exposure (which may be of several hrs. duration), place in contact with an orthochromatic plate sensitive to yellow in a frame having a screen transparent to infra-red light, and expose to a source of infra-red light. The latter acts on the "blacks" of the phosphorescent plate and renders them luminous (orange-yellow) so that they impress the orthochromatic plate, which is unaffected by the excess of infra-red so that the "whites" remain white.

The chemistry of selenium toning. A. AND I. LUMIERE AND A. SEYEWETZ. *Chimie et industrie, Special No.*, 416-7 (Sept., 1925).—In Se toning of chlorobromide papers, either with an alk. selenosulfide (NaSSe) or with hyposelenosulfite (Na₂SSeO₃), the image does not fix any S but is formed of a complex of Ag and Se. The ratio of Se:Ag is considerably higher in the toning of citrate than of chlorobromide papers. The quantity of Se fixed seems to be affected by the fineness of the grain of the image, increasing with the latter.

Contribution to the study of the properties of latent photographic images and their development in daylight after fixing. A. SEYEWETZ. *Chimie et industrie, Special No.*, 418-23 (Sept., 1925); cf. C. A. 19, 1825; Leffmann, C. A. 18, 205.—To reduce to a min. destruction of the latent image by the fixing bath, use a 30% Na₂S₂O₃ soln. contg. 10 cc. of aq. NH₃ (21° Bé.) per l., and do not fix more than 5 min. Caustic alkalis or Na₃PO₄ can be used instead of NH₃. Prolonged washing with water destroys the image, but no appreciable destruction takes place in 1 hr. The destruction is retarded if the water is alk., and accelerated if it is acid. If development is limited to 1 hr. the Ag grains are much smaller than those obtained in ordinary development; but they gradually increase in size by deposition of Ag if development is continued, and after about 10 hrs. they are of the same size as those obtained by ordinary development. The grains continue to grow on prolonging development still further, and tend to become hexagonal polyhedra, thus behaving like crystals. The image developed after fixing is highly transparent, but can be rendered more or less opaque by intensifying, during which the size of the Ag grains increases. Either fast or slow emulsions can be developed after fixing, even when given the normal exposure for the usual development before fixing.

The riddle of the photographic plate. F. C. TOY. *Phot. J.* 1925 (Exhibition number), 31-5.—Since the beginning of qual. photographic research the study of photographic densities as a whole has gone over to that of the grains, in particular and now would seem to be the study of the minute spots on the grain. The sensi-

tiveness of the emulsion is that of the component grains. Sheppard and his co-workers have shown that the sensitiveness of the grain is due to substances deposited locally from minute quantities of impurity in the gelatin used in emulsion making.

K. C. D. HICKMAN

Amidol: Its chemistry and use in development. J. G. F. DRUCE. *Camera Craft* 32, 334-6(1925).—The use of trioxymethylene, "stannous tartrate," metol, hydroquinol and adurol for decreasing the rate of oxidation of amidol is mentioned. An oxidized amidol developer is also recommended for use as a desensitizer.

B. LABAR

A proposal for a uniform expression of developing formulas. L. AUSSERWINKLER. *Phot. Rund.* 62, 139-40(1925).—To make various developer formulas comparable A. advocates expressing all quantities in moles per l. Molar quantities may be easily converted into g. by the use of a table of chem. formulas and at. wts. In a developer in which only the reducing agent and sulfite are used the molar concn. of the sulfite should be 6-8 times that of the reducer, while in a developer in which alkali is also used, the molar concn. of the sulfite should be 3-4 times that of the reducer.

M. W. SEYMOUR

A use for old fixing baths and developers. A. STEIGMANN. *Phot. Ind.* 1925, 731.—FeS gel is a suitable reagent for pptg. Ag from an old fixing bath. The mixt. of an old fixing bath with a used developer which contains quinonic substances might be made to produce useful dyes.

M. L. DUNDON

Contributions to development in bright light. A. HÜBL. *Phot. Rund.* 62, 111-7 (1925); cf. *C. A.* 19, 2305.—Used in the developer, a desensitizer has a greater effect than when used in the same concn. in a pre-bath. That this is not entirely due to the desensitizing action of oxidation products of the developer is shown by the fact that fresh developers also enhance the action of the desensitizer. The green-sensitiveness of a plate sensitized with eosin is almost totally destroyed by desensitizers while its blue-sensitiveness is reduced by only a fraction. The desensitizer should be added to the developer immediately before use, since it tends to ppt. in time.

M. W. S

Yellow fog of developing papers. R. G. ROCA. *Phot. Ind.* 1925, 808-10.—Yellow stain on prints is often due to colloidal silver and corresponds to dichroic fog on plates. It is caused by a Ag solvent in the developer such as too much sulfite, too high a temp. of development or the presence of developer in the print when put into the fixing bath. Papers differ greatly in their tendency to give such stain and for use in hot climates papers should be tested before general use.

M. L. DUNDON

Fixation of colored substances on positive silver images on glass or film. A. SEYEWETZ. *Bull. soc. franç. phot.* [3] 12, 197-208(1925).—The various mordants for basic dyes are enumerated as follows: AgI, Ag₄Fe(CN)₆, ferrocyanides of Pb, Cu, U, Fe and Co; Cr compds., Ag₂S, thiocyanates of Ag and Cu and the compd. resulting from the action of a mixt. of quinone and alkali Br on the Ag image.

J. I. C.

The effect of gelatin on photographic sensitivity. A. AND L. LUMIÈRE AND A. SEYEWETZ. *Rev. franç. phot.* 6, 291-2(1925).—The authors claim to have made discoveries in 1906 similar to those recently announced by Sheppard on sensitizing bodies in gelatin, but did not publish them for industrial reasons. One part of gelatin was digested with 10 parts of H₂O at 16° for 12 hrs., and then given nine successive washes with 5 parts of H₂O for 20 min. each. On evapn the extrn. water gave an active residue that sensitized inactive gelatin and contained S and N. Since 1910, as the result of trials of 900 substances a no. of materials have been used to modify emulsions. Some of these are esculin, salts of codeine, thebaine, diethylenediamine, thiocarbamide, guanidine thiocyanate and Cu and V salts.

O. COOK

The effect of dyes on the sensitivity of silver bromide gelatin. L. GORINI AND A. DANSI. *Phot. Ind.* 1925, 788-91.—The desensitizing power of several dyes was tested and results showed that they lie in the following order of increasing effectiveness: safranin, safranin, naphthosafranin, aminosafranin, diaminosafra-nine, phenosafranin, tolusafranin, pinakryptol, pinakryptol yellow, pinakryptol green. Plates were tested on a quartz spectrograph with a spark spectrum from electrodes of Eder's alloy and iron. The evidence did not support the hypothesis of Luppo-Cramer relative to the importance of amino groups in desensitizers.

M. L. DUNDON

The influence of desensitizers on the color of the developed image. LUPPO-CRAMER. *Phot. Ind.* 1925, 730-1.—The work of Milbauer and Lauschmann (*C. A.* 19, 2171) on this subject is shown to be in agreement with previously published work of L.-C. A colored image may be the result of slow surface development or it may be composed of colloidal Ag produced by physical development due to the presence of a Ag solvent.

M. L. DUNDON

Desensitizing with mercury salts. A. STEIGMANN. *Phot. Ind.* 1925, 490-2.—

Mercuric salts are probably adsorbed to Ag halide in minute amts. and act as oxidizing agents. They are not practically useful desensitizers but their action supports the oxidation theory of desensitization.

M. L. DUNDON

Imbibition printing. I. E. J. WALL. *Am. Phot.* 19, 600-12(1925).—Reliefs can be obtained by (a) developing with a developer such as pyrogallol whose oxidation product tans the gelatin; (b) by treating the developed image with a suitable chromic acid bath, and (c) by treating the Ag image with a bleach bath contg. H_2O_2 . The H_2O_2 is decomposed with the evolution of gas in the region of the Ag and this gas evolution disrupts the gelatin, which is then more easily washed away. Under (a) are recommended in the order of preference, pyrogallol, pyrocatechol and a pyrogallol mixt. Since the oxidized developer is the active agent, sulfite should be regarded as a restrainer. The following formula is recommended: pyrogallol 5 g., dry Na_2SO_3 2.5-10 g., KBr 3 g., Na_2CO_3 50 g., H_2O 1 l. In method (b) with $Na_2Cr_2O_7$ or CrO_3 , the gelatin is tanned by the action of the so-called chromium chromate, formed by interaction with the Ag image. A formula giving good results is: $K_2Cr_2O_7$ 25 g., H_2SO_4 10 cc., KBr 5 g., H_2O 1 l. A negative image is necessary for the third method (c) and a pyro-soda developer is to be preferred followed by fixation in an acid $Cr_2(SO_4)_3$ bath and thorough washing. Good results are claimed for the following etch bath: H_2O_2 330 cc., $CuSO_4$ 15 g., strong HNO_3 5 cc., KBr 0.5 g., water to make 1 l. Small variations in Br have a considerable effect on the action of the bath since the bromide acts as a restrainer.

G. E. MATTHEWS

Sodium sulfite as a fixing agent in the printing-out process. F. FORMSTECHER. *Phot. Ind.* 1925, 729-30. —A 9% soln. of Na_2SO_3 will dissolve 1 g. of AgCl per 100 cc. and can be used as a fixing bath for printing-out paper. It causes the whites to become stained and so is not practically useful. Its only use lies in sensitometry of such papers as it does not produce any fading of the printed-out image during fixation such as occurs with a $Na_2S_2O_3$ bath.

M. L. DUNDON

Silver bromide papers for bromoil prints. R. E. LIESEGANG. *Phot. Rund.* 62, 118-9(1925).—Some bromide papers are too hard, while others are too soft for the amount of swelling requisite for successful bromoil work. Even if the emulsion possesses the correct amt. of hardening immediately after manuf., it may alter and become useless in the course of a few months. Ordinarily the paper must be kept for one month and tested before it is marketed for bromoil purposes. To avoid waste of time, L. recommends acceleration of the aging process by keeping the paper in a moist warm atm. In two days, the paper reaches the same stage that would otherwise require one month. The entire roll of paper need not be so treated, but only a strip test.

M. W. SEYMOUR

Magnesium light for the sensitometry of photographic plates. J. M. EDER. *Phot. Ind.* 1925, 703-6. —Mg burning in air gives a nearly continuous spectrum and is suitable for a light source in sensitometry. Its exact spectral characteristics are discussed. Two mg. of Mg ribbon ignited by a non-luminous gas flame 3 m. from an Eder-Hecht wedge sensitometer provides satisfactory illumination for ordinary plates. A table is given based on a wedge const. of 0.40 in which for each Eder-Hecht no. the relative sensitivity, the Schwellenwert in m. c. s. and the corresponding Scheiner and H. and D. speeds are given.

M. L. DUNDON

Abrasion markings in film. ANON. *Filmtechnik* 1, 112-3(1925).—Expts. show definitely that the triboluminescent effect produced in film does not give enough light to reach the threshold value of even a high-speed emulsion. It is suggested that the abrasion marks result from an alteration of the space lattice structure of the AgBr crystals. All methods of preventing the development of abrasion, such as the use of KI, are open to practical objections and are not satisfactory. After-treatment with reducers is not successful. The best way of removing the abrasion is the mech. reduction of the film by rubbing with cotton soaked with alc.

O. COOK

Fluorescent screens. L. A. LEVY and J. W. MASON. *Brit.* 232,696, Jan. 25, 1924. A fluorescent screen consists of a thin sheet of cellulose nitrate or acetate or similar transparent waterproof material with which fluorescent material is incorporated, with an adhering backing sheet of celluloid or similar material.

Color screens for use in making or projecting pictures. K. RÄNRSCH and K. KÜBLER. *Brit.* 232,602, April 15, 1924. The screens may be made of gelatin, agar agar, fish glue, etc., and colored with various org. dyes such as fuchsin, crystal-violet or "patent blue."

Metallic screens for luminous projections. P. J. MARTIN. U. S. 1,557,530, Oct. 13. In prepg. screens for moving pictures or other projections, a coating of fine grains

of flint is applied to a plain backing, followed by a coating of Al contg. a small proportion of Au.

Packing photographic films or plates. PATHÉ CINÉMA ANCIENS ETABLISSEMENTS PATHÉ FRÈRES. Brit. 232,604, April 19, 1924. Sheets of gelatin, cellulose esters or other inert materials are interposed between sensitized coatings and wrappings of paper.

Reproducing half-tone printing plates. E. A. KUNZ. U. S. 1,559,710, Nov. 3. Chalk is rubbed upon the plate to fill up its depressions but leave the printing surface clean, the chalk is hardened and the plate is rolled with black ink and photographed.

Photomechanical printing plates. A. GALETZKA. U. S. 1,557,354, Oct. 13. A base such as Zn, Al, glass, cellon or stone is coated with an elastic non-sensitive layer such as pure gelatin and with an overlying sensitive layer and the object to be printed is photographically transferred onto the sensitive layer.

Photographic roll-film cartridges. PATHÉ CINÉMA, ANCIENS ETABLISSEMENTS, PATHÉ FRÈRES. Brit. 232,605, April 19, 1924. The paper protecting-band is coated with a "cellulose varnish" or other inert varnish on the side in contact with the sensitive coating of the film. Layers of gelatin also may be used.

Filter system for motion pictures in colors. J. SHAW. U. S. 1,562,066, Nov. 17.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Higher oxides of silver. I. Ag₂O₂. FRANZ JIRSA. *Z. anorg. allgem. Chem.* **148**, 130-40 (1925).—See C. A. **19**, 2460. E. J. C.

The constitution of manganese hydroxide. FELIX HEBLER. *Farben-Ztg.* **31**, 155-6 (1925).—Com. Mn hydrates are of variable compn. and their variously ascribed formulas are Mn₂O₃·H₂O, MnO₂(OH)₂, HMnO₂, etc. Actually they are hydrogels, analogous to the Fe hydroxides, and their H₂O content is dependent on the method of manuf., their age, the temp. and vapor pressure of the surrounding air, etc. It is therefore impractical to try to express analytical results on Mn hydrates by formulas.

F. A. W.

The meaning of manganese hydroxide (Manganoxhydroxyhydrat). FELIX WILBORN. *Farben-Ztg.* **31**, 338-9 (1925); cf. preceding abstr.—The naturally occurring manganite is a well-defined compd. of compn. Mn₂O₃·H₂O; and compds of the same definite compn. have been produced by various methods by several experimenters. Some of the com. compds. owe their indefinite compn. to the method of manuf. by pptn. of an aq. soln. of a Mn salt with alkali. The resultant Mn(OH)₂ rapidly oxidizes to a hydrated Mn₂O₄ and is then slowly converted to a colloidal hydrated Mn₂O₃. Other com. processes produce a product of much more uniform compn. F. A. WERTZ

A new complex of osmium. I. CHUGAEV. *Z. anorg. allgem. Chem.* **148**, 65-8 (1925).—(Published by E. Fritzmann.) Only one series of basic osmium salts, (OsO₄·4NH₃)X₄, was known previously. When Na₂OsCl₆ and CS(NH₂)₂ were heated to boiling in H₂O and cooled with addn. of much HCl and LiCl, 2 products resulted. The one, sol. in EtOH (reddish brown leaflets), was Os 6(NH₄·CSNH₂) Cl₃OH, the Os having a valence of 4 and coordination no. 6. Cryoscopic and cond. data show 4 ions. Fritzmann states that the formation of the chloride of this base is a *qual. test* for Os. On boiling H₂O 5 min. with CS(NH₂)₂ and HCl the soln. turns bright red in the absence of Os, and rose color with 0.001% Os. Similar tests with pyridine, picoline, quinoline and urotropine are mentioned.

A. W. FRANCIS

Products of oxidation of complex sulfites of trivalent cobalt. G. SCAGLIARINI AND G. TARTARINI. *Atti accad. Lincei* [6], **2**, 191-4 (1925).—Many sulfates and sulfites are known in which Co constitutes part of the complex cations or anions but only a few are known in which it constitutes part of both ions. The purpose of this work was to obtain oxidation products of the cobaltamine sulfites (cf. Riesenfeld, C. A. **18**, 1092). A suspension of CoCO₃ in H₂O was treated with excess SO₂. To this soln. (NH₄)₂CO₃ was added in slight excess to neutralize all of the SO₂. The yellow-brown soln. was fld. and exposed to the light and air for 10 days and sepd. yellow-gold crystals of the cobaltiaquodisulfite monosulfate of hexamminecobalt, Co(NH₃)₆ Co(SO₃)₂(SO₄)(H₂O)₃·2H₂O, stable in the air. Through a soln. like the above, but more concd., a current of air was passed and the cobaltiaquotrissulfate of aquotriamminecobalt, [Co(NH₃)₃(H₂O)₃]₂·[Co(SO₄)₂(H₂O)₃], was sepd. as yellow crystals insol. in H₂O. It was difficult to obtain this salt free from less thoroughly oxidized products. It is logical to assume that the complex [Co(NH₃)₆]₂[Co(SO₃)₂(H₂O)₃] is first formed (cf. Künzel, *J. prakt. Chem.* **72**, 209

(1857)) and that this by successive oxidation forms the mono-, di- and trisulfate complexes having the following anions: $\left[\begin{smallmatrix} (\text{SO}_3)_2 \\ \text{Co}(\text{SO}_4) \\ (\text{H}_2\text{O})_2 \end{smallmatrix} \right]'''$, $\left[\begin{smallmatrix} (\text{SO}_4) \\ \text{Co}(\text{SO}_4)_2 \\ (\text{H}_2\text{O})_2 \end{smallmatrix} \right]'''$ and $\left[\begin{smallmatrix} (\text{SO}_4)_3 \\ \text{Co} \\ (\text{H}_2\text{O})_2 \end{smallmatrix} \right]'''$.

The disulfate is still lacking to complete the series. The insol. of these complex salts in H_2O makes it impossible to obtain salts contg. other metals in place of the cobalt-ammino cation.

E. J. WITZEMANN

The chemistry of lithium. V. The polybromides and polychlorides of the alkalis. G. F. HÜTTIG AND OTTO SCHLIESSMANN. *Z. anorg. allgem. Chem.* **148**, 87-92(1925).—The existence of compds. between alkali halides and the corresponding halogens was tested by elaborate pressure measurements at various temps. No evidence was found for LiBr_3 , LiCl_3 , KCl_3 , CsCl_3 nor CaCl_4 , the pressures being practically the same as for pure halogen, and the monohalides being almost insol. in the halogens. The pressure indicated the existence of RbBr_3 , which decompd. in the range 35° to 78° ; and probably also NH_4Br_3 , but this was not completely stable at 0° .

A. W. FRANCIS

The reduction of tungstates. VICT. I. SPITZIN. *Z. anorg. allgem. Chem.* **148**, 69-83(1925).—Acid or neutral tungstates of the alkalis or alk. earths, when ignited and reduced by various means, give "tungsten bronzes," which are compds. of the type, $\text{Na}_2\text{O} \cdot \text{WO}_2 \cdot n\text{WO}_3$, have metallic luster and bright colors, and are resistant to acids, alkalis and aqua regia, etc., but can be dissolved with ammoniacal AgNO_3 . The necessary conditions for the formation of any one compd. were not known previously. Na_2WO_4 , $\text{Na}_2\text{W}_2\text{O}_7$, $\text{Na}_{10}\text{W}_{12}\text{O}_{41}$, $\text{Na}_2\text{W}_4\text{O}_{13}$, and $\text{Na}_2\text{W}_6\text{O}_{16}$, resp., were heated in an elec. oven in a stream of H_2 at various temps. At 650 - 700° the only residues were Na_2WO_4 and W as shown by the wt. loss of O. At higher temps. the bronzes were formed in the order, blue-violet-red-yellow. At 900° reduction to W was complete; Na_2O was also volatilized.

A. W. FRANCIS

Reducing power of sodium hyposulfite in alcoholic solution. JOS. POKORNY. *Rev. gen. mat. color.* **29**, 288(1925); cf. *C. A.* **19**, 3228.—To 2000 cc. of ordinary denatured alc. is added 100 g. $\text{Na}_2\text{S}_2\text{O}_4$ (concd. powder B. A. S.) and the silk, previously moistened and dried, is introduced. No reaction is apparent. Upon the addn. of 600 cc. H_2O , a brisk reduction takes place and the silk is bleached. The reduction is so energetic that indigo on bits of cotton used as test pieces is not reoxidized by dichromate, although a similar test with an aq. soln. of $\text{Na}_2\text{S}_2\text{O}_4$ shows a ready reoxidation. The bleaching operation requires about 15 min. The white obtained is much superior to the white produced by an aq. soln. of $\text{Na}_2\text{S}_2\text{O}_4$.

L. W. RIGGS

The relations of zirconium phosphate toward acids and bases. J. H. DE BOER AND A. E. VAN ARKEL. *Z. anorg. allgem. Chem.* **148**, 84-6(1925).—Phosphates of Hf and Zr only are insol. in strong mineral acids. $\text{Zr}_3(\text{PO}_4)_4$ is sol. in HF and, if freshly pptd., in concd. H_2SO_4 and $(\text{COOH})_2$. It dissolves even in the cold in strong NaOH in the presence of org. oxy-acids, e. g., tartaric, malic and lactic, and polyatomicals, with OH groups on adjacent C atoms, e. g., glycerol glucose, sucrose, pyrocatechol, pyrogallol, but not with hydroquinone, phloroglucinol, and picric acid, etc. When such solns. are nearly neutralized with acid, $\text{Zr}(\text{OH})_4$ is pptd. PO_4^{---} can be pptd. from the solns. with BaCl_2 . $\text{Zr}(\text{OH})_4$ is dissolved by NaOH and H_2O_2 , forming a perzirconate which gives a cryst. ppt. with EtOH. Hf shows similar reactions.

A. W. FRANCIS

Addition compounds between halides of tin and of titanium with organic bases. G. SCAGLIARINI. *Atti accad. Lincei* [6], **2**, 269-74(1925).—In extending some previous work on addition compds. of halides of Sn and Ti (*C. A.* **19**, 2789) addn. compds. with org. bases were prepd. A cold satd. soln. of SnCl_4 in CHCl_3 was treated gradually with a cold satd. soln. of caffeine in CHCl_3 and gave a white cryst. ppt. of the addn. compd. $4\text{SnCl}_4 \cdot 3\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{CHCl}_3$. A soln. of SnBr_4 treated similarly gives $2\text{SnBr}_4 \cdot 3\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot 3\text{CHCl}_3$ as a yellow ppt. An insufficient amt. of a soln. of SnI_4 in CHBr_3 was added to a soln. of hexamethylenetetramine (I) in CHBr_3 and gave a yellow cryst. ppt. of $\text{SnI}_4 \cdot 4\text{C}_6\text{H}_{12}\text{N}_4 \cdot 5\text{CHBr}_3$. A cold concd. soln. of SnI_4 in CHBr_3 was added dropwise to a soln. of (I) and gave a dark violet ppt. of $\text{SnI}_4 \cdot 5\text{C}_6\text{H}_{12}\text{N}_4 \cdot 8\text{H}_2\text{O}$. A dil. soln. of TiCl_4 in CHCl_3 was added to a cold satd. soln. of I in CHCl_3 and gave a white ppt. of $\text{TiCl}_4 \cdot 12\text{C}_6\text{H}_{12}\text{N}_4 \cdot 3\text{CHCl}_3$. An excess of a satd. soln. of I in CHBr_3 was treated with a soln. of TiCl_4 in CHBr_3 and pptd. yellow $\text{TiI}_4 \cdot 4\text{C}_6\text{H}_{12}\text{N}_4 \cdot 5\text{CHBr}_3$. In these addn. complexes the solvent also enters. The halogenated solvents were used because of their low dielectric consts. which appear to be necessary to impede the ionization of the halides used and to reveal the secondary valences to a max. degree for the formation of complexes. The structure of these compds. is difficult to interpret and Werner's coordination theory is inadequate.

E. J. WITZEMANN

Ferric acid and ferrates. L. LOSANA. *Gazz. chim. ital.* **55**, 468-97(1925).—

K_2FeO_4 was prepd. by 2 methods: (1) according to Fremy Fe powder was thrown into fused KNO_3 ; the yield is small; (2) a rapid current of Cl_2 was passed through a suspension of $Fe(OH)_3$ in concd. KOH . K_2FeO_4 is insol. in KOH but the product contains $Fe(OH)_3$ and KOH , which cannot be removed by washing. CO_2 decomp. K_2FeO_4 easily. A soln. of K_2FeO_4 with $Ba(NO_3)_2$ ppts. $BaFeO_4$, which is even more sensitive to CO_2 . Ag_2FeO_4 was best prepd. by suspending 5 g. finely powdered $BaFeO_4$ in 50 cc. boiled H_2O . To this was added the calcd. amt. of $AgNO_3$ in 50 cc. H_2O . After 6 hrs. the red $BaFeO_4$ had disappeared and black Ag_2FeO_4 remained. Hg_2FeO_4 was prepd. similarly. A 2.5% soln. of $TiNO_3$ reacting as above with $BaFeO_4$ gave a brown powder, a mixt. of 2 compds. $SrFeO_4 \cdot 2H_2O$ and $CaFeO_4 \cdot 2H_2O$ were prepd. like $BaFeO_4$. 2% $Hg(NO_3)_2$ with $BaFeO_4$ as above did not give $HgFeO_4$. $CuFeO_4$, $PbFeO_4$, $ZnFeO_4$, $NiFeO_4$, $CoFeO_4$, $Fe(FeO_4)$, $Al_2(FeO_4)_3$, $Fe_2(FeO_4)_3$, $Cr_2(FeO_4)_3$, $Th(FeO_4)_2$ were all prepd. similarly. A detailed study of the properties of these compds. was made. The salts of Ag, Ba, Sr, Ca, Cu, Pb, Zn, Ni and Co could be dried without decompn. and analyzed; their thermal decompn. was studied systematically. Those of Fe'' , Fe''' , Al and Th were too unstable to be dried. With Mn, Ti and Hg^I definite products could not be obtained; Mg does not react at all. The ferrates of Ba, Sr, Ca and Cu contain H_2O that is held even when they are dried to const. wt. over H_2SO_4 . Those of Ba and Sr lose this H_2O at temps. below the decompn. temp., and therefore these can exist in the hydrated and anhydrous state. Those of Ca and Cu lose this H_2O in the evolution of the active O_2 . The thermal decompn. of the ferrates takes place according to the following reactions: (1) $4M_2FeO_4 \rightarrow 4M_2O + 2Fe_2O_3 + 3O_2$; (2) $4MFeO_4 \rightarrow 4MO + 2Fe_2O_3 + 3O_2$; (3) $4M_2(FeO_4)_3 \rightarrow 4M_2O_3 + 6Fe_2O_3 + 9O_2$; (4) $2M(FeO_4)_2 \rightarrow 2MO + 2Fe_2O_3 + 3O_2$. The active O_2 is always $\frac{3}{8}$ of the total O present. $Fe(FeO_4)$ is an exception to this rule. The active O_2 is only $\frac{1}{4}$ of the total amt. and this may be interpreted by 2 successive reactions: (1) $4FeFeO_4 \rightarrow 2Fe_2O_3 + 4FeO + 3O_2$; (2) $4FeO + O_2 \rightarrow 2Fe_2O_3$ and by adding these $4FeFeO_4 \rightarrow 4Fe_2O_3 + 2O_2$. The temp. of decompn. of the various ferrates is variable: the Ba salt loses H_2O at 108° and decomp. at 123° , while the Sr and Ca salts decomp. at lower temps. and those of Ni and Co are decompd. at 30° . All of these compds. decomp. continuously when heated to the proper temp. except $BaFeO_4$. The decompn. of $BaFeO_4$ at 123° proceeds to a compn. corresponding to $BaFeO_3$ and remains unchanged until 144° is reached, when it gives up the remaining calcd. amt. of active O . The compds. of univalent metals are unstable and those of the bivalent metals behave irregularly. The ferrates of the trivalent metals are more unstable than those of the bivalent metals and less than those of the quadrivalent metals. Some of the ferrates remain unchanged when kept *in vacuo* over H_2SO_4 at $15-20^\circ$, while others lose H_2O and active O . The compds. of Ba and Sr lose neither H_2O nor O_2 ; those of Ca and Pb give a slow but complete decompn.; the salts of Ag, Cu, Zn, Co and Ni change rapidly; nothing can be said about the decompn. of the others, because they changed too rapidly. The compd. $FeFeO_4$ showed physical and chem. properties by which it could be identified as FeO_2 prepd. in another way by Pellene and Meneghini (*Gazz.* 39, I, 381(1909); cf. C. A. 4, 428). In $Fe_3(FeO_4)_4$ the ratio $Fe:O$ was greater than 2. In some cases in which the products are capable of secondary oxidations various final products are obtained. In the case of Mn a mixt. of various higher oxides is probably obtained and with the Cr salt H_2CrO_4 seems to be formed. Other work on these compds. is under way.

E. J. WITZEMANN

A carbonyl compound of gold. W. MANCHOT AND H. GALL. *Ber.* 58B, 2175-8 (1925); cf. C. A. 18, 3559; 19, 941, 942, 1544.—By periodic arrangement of the metals which form carbonyl compds., certain analogies are observed: the behavior of Au is particularly striking. CO unites with anhyd. $AuCl_3$ readily at 95° ; $AuCl$ or $AuBr$ may also be used, but with no advantage. Strongly refractive, colorless crystals of $AuCl \cdot CO$ are produced. The compd. is unstable, and must be protected from moisture and light.

ROSALIE COBB

A carbonyl compound of rhodium. W. MANCHOT AND J. KÖNIG. *Ber.* 58B, 2173-4 (1925).—The union of CO with hydrated $RhCl_3$ proceeds readily at 140° . Dark red needles of $Rh_2Cl_4 \cdot 3CO$ result, m. 125.5° ; they are sol. in H_2O , CCl_4 , glacial $AcOH$, and benzene. The melt has a blue fluorescence. On standing or heating the solns. become turbid through sepn. of Rh, and they reduce ammoniacal solns. of Ag salts. $Pb_2Cl_2 \cdot 3CO$ reacts strongly with H_2SO_4 . The difference between the formula of the Rh carbonyl compd. and that of $Pt(PtCl_2 \cdot 3CO)$ emphasizes the tendency of Rh to form basic salts.

ROSALIE COBB

The preparation of auric chloride. MARC PETIT. *Bull. soc. chim.* 37, 1141-7 (1925); cf. C. A. 19, 2592.—P. reviews the previous results of Debray, Thomsen, Kruss, Rose, Lindet and Meyer and attempts to det. the optimum conditions for the prepn.

of pure, anhyd. cryst. AuCl_3 but limits himself to the use of liquid or gaseous Cl_2 . Action of liquid Cl_2 . Gold leaf in a sealed tube of liquid Cl_2 becomes coated with fine red needles of AuCl_3 . Soly. of the crystals in the Cl_2 , the difficulty of control and the small yield render this method unsatisfactory. Action of gaseous Cl_2 . P. passes Cl_2 at a pressure of 6-8 cm. of Hg above atm. at a rate of 2 bubbles per sec. over leaf gold heated in a tube furnace especially designed to allow temp. control and to facilitate collection of the resulting sublimed chloride. The yield starts at 180° , increases to a max. at 250° and then decreases. The following results at 3 temp. ranges were fairly const. and agree with the results of Rose and with expectations based on dissociation and vapor pressures. $223-228^\circ$, 0.095 g. per hr., 70%; $245-250^\circ$, 0.150 g. per hr., 79%; $300-310^\circ$, 0.040 g. per hr., 62%. The yield percent is the ratio between the yield and the amt. of AuCl_3 corresponding to the loss in wt. of the gold leaf. Pressures greater or less by 20 cm. of Hg than atm. were not feasible with the app. used. After long runs a decrease in the yield results, apparently due to the coating and toxic effects of AuCl on the gold leaf. Conclusion. The action of Cl_2 at pressures slightly above atm. upon Au at a temp. of 250° is most favorable to the production of pure, anhyd., cryst. AuCl_3 . P. B. P.

Systematic affinity principle. Ammoniates of halides in the iron group, of Be halides, of Cd and Hg halides, of aurohalides and of cuprihalides (BILTZ, *et al.*) 2.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Contradictions and errors in analytical chemistry. VI. The ferrous sulfate test and the diphenylamine reaction. FRIEDRICH L. HAHN AND GUSTAV JAEGER. *Ber.* 58B, 2340-3(1925) - Faurholt (*C. A.* 17, 1199) was not able to detect 10 mg. of KNO_3 in 2 cc. of soln. by means of the well-known ring test with FeSO_4 . If the test is properly applied, however, 0.1 mg. of KNO_3 can be detected in 1 cc. of soln. To the nitrate soln. add 0.2-0.3 as much of a satd. soln. of FeSO_4 contg. some H_2SO_4 . Mix and add an excess of H_2SO_4 or, if HBr is present, sirupy H_3PO_4 . Not more than 10 mg. of NaBr should be present. In the diphenylamine reaction the test is positive with 1 cc. of soln. contg. 0.1 mg. HNO_3 per l. if carried out as recommended by Tillmans (*C. A.* 5, 3211) but the reaction is not as specific as might be desired and is often affected by oxidizable or reducible substances in the concd. H_2SO_4 used. W. T. H.

Diphenylamine test. LAD. EKKERT. *Pharm. Zentralhalle* 66, 649-50(1925).—The color changes produced with HNO_3 , HNO_2 , HClO_4 , HClO_3 , HBrO_3 , HIO_3 , H_2CrO_4 , $\text{H}_2\text{Cr}_2\text{O}_7$, H_2MoO_4 , HVO_3 , $\text{H}_3\text{Fe}(\text{CN})_6$ and H_2O_2 are described as well as the effect of HCl , H_2SO_4 , H_3PO_4 , CHCl_3 and EtOH upon the colors. W. O. E.

Solid hydrogen peroxide. A new analytical reagent. J. R. BOOER. *Chemistry and Industry* 44, 1137(1925).—An account of the properties of *hyperol*, a solid compd. of H_2O_2 and urea of the formula, $\text{CO}(\text{NH}_2)_2 \cdot \text{H}_2\text{O}_2$, which is advantageous as a substitute for H_2O_2 solns. in the lab. W. T. H.

The use of sodium rhodizonate as a reagent for barium, strontium and lead. I. M. KOLTHOFF. *Pharm. Weekblad* 62, 1017-20(1925).—The di-Na salt of rhodizonic acid (1,2-dihydroxyquinoyl) which Feigl (*C. A.* 19, 1108) proposes as a reagent for Ba and Sr is also a sensitive reagent for Pb in neutral soln. The reagent readily oxidizes in aq. soln. and should be freshly prepd. The test for Ba and Sr is rendered much more delicate by the addn. of an equal vol. of EtOH . A. W. DOX

The determination of nitrate nitrogen. G. H. G. LAGERS. *Verslag. Land. Onderzoek. Rijkslandbouwproefsta.* 30, 224-48(1925).—A comparison of the Schlösing, the Devarda, the Arndt, and the Ackermann method for the detn. of nitrate N was made with the conclusion that the Ackermann method alone was unsuitable as a comparative method. R. M. BARNETTE

An extremely sensitive and altogether specific test for nitrate. F. L. HAHN AND GUSTAV JAEGER. *Ber.* 58B, 2335-40(1925).—By the diazo test (reddening of sulfanilic acid and α -naphthylamine in AcOH) it is possible to detect 0.001 mg. of NaNO_3 in 1 l. of aq. soln. by using only 1 cc. Directions are given for prepg. the diazo reagent, water free from HNO_2 , for reducing HNO_3 to HNO_2 by means of Pb formate, and for applying the test for the detection or approx. colorimetric detn. It was found difficult to reduce HNO_3 quant. to HNO_2 alone but if 1 mg. of alkali nitrate is present per l. it is easy to get a good test and by comparison with a series of standards it is possible to det. fairly closely the alkali nitrate content when only a few mg. are present per l. This test is more sensitive than the ring test with Fe^{++} and, unlike the diphenylamine reaction, is not

common to other oxidizing agents. The original paper must be consulted for details concerning preparing the reagents and method of applying the test. W. T. H.

A volumetric method of assaying mercuric iodide, mercuric chloride, and some other mercury compounds. S. ELLMAN. *Am. J. Pharm.* 97, 672-4(1925).—E. recommends the following procedure: Dissolve about 0.5 g. of dried HgI_2 in 10 cc. of a 20% KI soln. Dil. to 50 cc., sat. with H_2S and allow the ppt. to settle. Filter and wash the ppt. with cold distd. water. Transfer the filter paper with the ppt. to a 250-cc. flask, add 10 cc. of 20% KI soln. and 30 cc. of 0.1 N I V. S. Stopper tightly with a paraffined cork through which a glass tube is passed connecting with a 50-cc. flask contg. 10 cc. of KI soln. (10%). Place the 250-cc. flask on a water bath and heat for about $\frac{1}{2}$ hr. Shake the 250-cc. flask from time to time till no more black particles are visible. Now cool and wash the tubing and cork with the KI soln. of the smaller flask and titrate the contents of both flasks with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. $\text{HgS} + \text{I}_2 = \text{HgI}_2 + \text{S}$. $\text{HgI}_2 + 2\text{KI} = \text{K}_2\text{HgI}_4$. The excess of I is titrated. W. G. GAESSLER.

Analysis of materials containing a mixture of metallic iron and iron oxides. H. C. M. INGELBERG. *Ind. Eng. Chem.* 18, 1261-2(1925).—(1) Det. the total Fe. (2) Det. the tervalent Fe after treatment with KCuCl_4 and citric acid, finally dissolving the residue in HCl. (3) Det. the quantity of Cl_2 required to oxidize all the Fe to the tervalent condition. To do this, treat the material in a Bunsen app. with KCuCl_4 and FeCl_3 in an atm. of CO_2 . After 3 hrs. add 1 g. of MnO_2 and det. the Cl_2 evolved iodometrically. Test the MnO_2 alone to det. how much served to oxidize the Fe. W. T. H.

Assay of potassium chlorate. A comparison of methods. LABORATORIES OF LEHN AND FINK. *Ind. Eng. Chem.* 17, 1277-8(1925).—Methods depending on the reduction of chlorate to chloride proved unsatisfactory. A method based on the reduction of by standard TiCl_3 is accurate but impractical. The method outlined in the U. S. Pharmacopoeia is accurate but the modification used by the Frankford Arsenal is in some respects better. This method depends on the treatment of 0.1 g. KClO_3 in 35 cc. of water with 50 cc. of 4% Mohr's salt soln. After boiling 2 min. with a Bunsen valve in the neck of the flask, the excess of Fe^{++} is titrated. W. T. H.

The evaluation of chlorates. E. C. WAGNER. *Ind. Eng. Chem.* 17, 1183-6(1925).—Bunsen's evolution method, the iodometric method of Ditz involving an original treatment with KBr and HCl , the iodometric method of Kolb and Davidson based on the direct treatment with KI and HCl , the FeSO_4 method involving the titration of the excess Fe^{++} with KMnO_4 and the gravimetric methods based upon reduction to chloride by ignition with NH_4Cl , evapn. with HCl or reduction with SO_2 were all tested very carefully. All of the 7 methods, except that of Kolb and Davidson, were found to be accurate and suitable for exact analytical work. The volumetric methods are excellent for routine work especially the FeSO_4 method. In the gravimetric way, the reduction with HCl is simplest but reduction with SO_2 and subsequent pptn. as AgCl is more accurate. W. T. H.

The electrometric titration of fluoride ions. W. D. TREADWELL AND A. KÖHL. *Helvetica Chim. Acta* 8, 500-7(1925).—Based on the work of Guyot, Grefci (C. A. 7, 3939) has shown that F^- can be titrated by means of Fe^{+++} with CNS^- as indicator. The method is based upon the formation of the complex anion $(\text{FeF}_6)^{---}$. If, however, less than 20 mg. of F is present, the end point is obtained too soon and the method is inaccurate. The same reaction can be utilized for an electrometric titration and if the end point is obtained in this way, the method can be adapted to the detn. of as little as 0.1 mg. F. For titrating 0.5 mg. or more of F, use not over 100 cc. of concd. soln. which has been made barely acid to phenolphthalein, satd. with NaCl and made to contain about 48% alc. Stir the soln. by means of a stream of CO_2 and titrate with 0.1 N FeCl_3 soln. contg. about 1% of FeCl_3 . When a little more than enough FeCl_3 than is required to form the complex fluoride ion has been added, there is a sudden change in the Fe^{++} - Fe^{+++} oxidation potential as shown by the millivoltmeter which is connected directly to an AgCl standard cell and is in circuit with a Pt wire dipping into the soln. With smaller app., the method can be made more sensitive. A series of expts. was made along similar lines with elements other than Fe for the titration of F^- ions, with Cr, V, U, Ti, Cb, Zr, etc., but none proved as good as Fe. By means of conductometric titration, it is possible to titrate F^- with Al^{+++} but the results have not proved altogether satisfactory. W. T. H.

Detection of sodium as oxalate. L. W. WINKLER. *Pharm. Zentralhalle* 66, 600-79(1925).—The addition of a satd. soln. of $\text{K}_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$ and alc. causes the pptn. of less sol. Na oxalate. The test is about as sensitive as the tartrate test for K. Directions are given for applying the test to various typical Na compds. W. O. E.

Volumetric estimation of ortho-, pyro- and meta-phosphoric acids in mixtures. S. AOYAMA. *J. Pharm. Soc. Japan* No. 520, 553-6 (1925).—Make the soln. neutral with NaOH, add a measured vol. of 0.1 N AgNO₃, and add enough alc. to make the content 50%. Filter, wash with 50% alc. and det. excess Ag by the Volhard method. Call *a* the Ag required to ppt. the 3 acids. Treat the ppt. with H₂S water, filter off the Ag₂S and wash till the filtrate is neutral to methyl orange. Conc. to 40°, keeping the temp. below 40°, and add 100 cc. of satd. NaCl soln. Titrate first with NaOH, using methyl orange (to get the result *b*) and then phenolphthalein (to get the result *c*). Then if *x*, *y* and *z* represent the millimols. of H₃PO₄, H₄P₂O₇ and HPO₃, resp., and *a*, *b* and *c* are expressed in milli-equivs. then $3x + 4y + z = a$, $x + 2y + z = b$ and $2x + 4y + z = c$. S. T.

A new method for measuring the dust in air and industrial gases. W. ALLNER. *Farbe u. Lacke* 1925, 451.—The dust collector recommended consists of a cylinder provided with suitable filter cloths which are removable for weighing. The correct detn. of the dust content in gas streams is possible only when the pressure in the sampling tube is identical with that in the main stream. F. A. WERTZ

The separation of zirconium from iron. P. WENGER AND M. MÜLLER. *Helvetica Chim. Acta* 8, 512-3 (1925).—When ZrO₂ is fused with soda, some Na zirconate is formed which is insol. in water but sol. in hot HCl. For technical work, however, the Zr can be sepd. fairly well from Fe, Si, etc., with a loss of only about 0.5% ZrO₂ as follows: Fuse the sample with 6 times as much soda in an open Pt crucible for 2 hrs. Extract the melt with warm water, filter and wash with dil. NH₄NO₃ soln. Ignite the residue strongly and digest 2 hrs. with concd. HCl on the water bath. After dilg. and filtering nearly all the ZrO₂ remains unattacked. W. T. H.

Determination of butadiene with other gaseous olefins. B. SOROKIN AND A. BELIKOV. *J. Ind. Chem. (Russia)* 1, 28-9 (1925).—Better results than by the usual brominating method were obtained by chlorinating butadiene with a 14.5% soln. of Cl in CCl₄. The gas contg. butadiene was passed through 3 flasks contg. the chlorinating soln. at 0°. The contents of the flasks were mixed and after 2 hrs. standing, the excess Cl was neutralized with soda, the chlorinated liquid product washed with water, dried over CaCl₂, the CCl₄ removed by evapn. and the residue fractionated. After this treatment, propylene and isobutylene gave a mixt. of chlorides but butadiene gave the tetrachloride (m. p. 70°; b. p. 118-22°) and the yield was at least 95% of the theoretical. BERNARD NELSON

Systematic detection of traces of aldehydes. E. C. CROCKER. *Ind. Eng. Chem.* 17, 1158-9 (1925).—Detailed directions are given for applying various tests for aldehydes and the sensitivity of the tests is indicated. Odor is a good indication especially for the higher aliphatic aldehydes. The fuchsin test is rapid and very suitable for detecting HCHO. The resorcinol test is sensitive and also very good for HCHO. The phloroglucinol test distinguishes between aliphatic and aromatic aldehydes and is somewhat selective in the aromatic series. Guaiacol is splendid for HCHO and other aliphatic aldehydes. The aniline test indicates moderate amts. of cyclic aldehydes. The Ag reduction test is sensitive but likely to be caused by other reducing agents. W. T. H.

The analysis of a mixture of aniline and toluidines. H. F. LIDDELL. *J. Soc. Chem. Ind.* 44, 506T (1925).—If these bases are present in a large vol. of aq. soln. the conventional method of analysis is tedious. For a soln. contg. 10-20 g. of mixed amines per l. the following procedure has proved satisfactory: To 50 cc. of soln. add a slight excess of acid and titrate with NaNO₂ in the usual way, keeping the temp. below 5°. Mix another 25 cc. of soln. with 25-30 cc. of 45% HBr and titrate with 3.34% KBrO₃ soln. Then, if *a* is the wt. of NaNO₂, *b* the Br equiv., *x* the wt. of aniline and *z* the wt. of toluidine per l., then $x = 0.5813b - 2.696a$ and $z = 4.632a - 0.6688b$. W. T. H.

Cochineal, the utility of assay methods in the estimation of comparative color values. A. O. BENTLEY AND S. MEAKIN. *Pharm. J.* 115, 135-7, 178; *Chemist & Druggist* 103, 175-6 (1925).—The ordinary methods for the estn. of cochineal are of little use in the valuation of the color of the soln. This color varies according to the H-ion concn. which is influenced by the methods of killing the insects, and the common adulterants used. However, the colors can be controlled by including AcONa as a buffer soln. As the amt. of cochineal (10%) in the official tincture is needlessly high, the following formula is proposed: cochineal 50 g., N NaOH 7 cc., N AcOH 10 cc., 90% EtOH 500 cc., H₂O 510 cc. Macerate the drug in the mixed liquids for 48 hrs., strain through glass wool, set aside for 2 weeks, then filter. The amt. of buffer mixt. used is sufficient to control the color even on diln., but is small enough to be without pharmacol. action. S. WALDBOTT

New color reaction for lactic acid. L. EKKERT. *Pharm. Zentralhalle* 66, 552-3

(1925).—Dissolve a few cc. pyrocatechol in 5 to 6 cc. of concd. H_2SO_4 , then superimpose thereon 1 to 2 cc. of dil. lactic acid (3 drops of 75% lactic acid in 10 cc. H_2O), whereupon a bright blood-red color develops. The test is sensitive to a diln. of 0.02% lactic acid.
W. O. E.

The detection of sugar by the Molisch-Udransky reaction. J. C. L. DEFIZE. *Chem. Weekblad* 22, 467-8(1925).—A positive M.-U. test may be given by pure water which has been filtered through ordinary filter paper, unwashed with HF. The positive test may be due to the hydrolysis of cellulose fibers carried with the filtrate, or to the presence of oxycellulose in the unwashed paper.
DONALD W. MACARDLE

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

Tenth list of new mineral names; with an index of authors. L. J. SPENCER. *Mineralog. Mag.* 20, 444-77(1925).—S. lists 167 new names that have appeared since 1922. A brief description including compn. and reference to the original article is given in each case.
W. F. HUNT

Iron coloration in rocks and minerals. G. R. MACCARTHY. *J. Elisha Mitchell Sci. Soc.* 41, 135-7(1925).—Analysis of Fe-bearing rocks and minerals and calcn. of the ferrous-ferric ratio led to the following conclusions: Ferrous compds. occurring in rocks and soils are colorless or nearly so. Ferric compds. are brown, red or yellow according to the concn. Hydrous ferroso-ferric compds. are blue. The black color of certain Fe minerals may be due to dehydration of ferroso-ferric compds. Mixts. of ferroso-ferric with large and small proportions of ferric compds. are colored purple and green, resp. Three references are appended.
A. L. MEHRING

Native iron in granite injections and mica schists from Oulmes. G. CORNAND. *Ann. soc. géol. Belg.* 48, 386-8(1925).—Small elongated metallic particles with apophyses extending between the mineral grains have the phys., chem. and magnetic properties of Fe. The metal is coated in places with oxide and elsewhere with a yellow stain believed to be sulfide.
O. F. POINDEXTER

The structure of aragonite. S. I. TOMKEIEFF. *Mineralog. Mag.* 20, 408-34(1925).—A new method is presented for detg. the leptonic structure of crystals from their etch-figures. This method applied to aragonite indicates it to be monoclinic-holoedra. The monoclinic leptons (groupings of Ca, C and O atoms) are arranged on an orthorhombic space-lattice, so that aragonite is pseudo-orthorhombic.
W. F. HUNT

Calcite and barite from Bioul. H. BUTTENBACH. *Ann. soc. géol. Belg.* 48, B63-8(1925).—Crystallographic descriptions are given.
O. F. POINDEXTER

Albite and other authigenic minerals in limestone from Bengal. EDMONDSON SPENCER. *Mineralog. Mag.* 20, 365-81(1925).—Idiomorphic albite crystals were found disseminated in certain zones in a limestone at Raipure, India. It is highly probable that this feldspar is authigenic in origin, and the same seems true of the associated quartz, mica, pyrite, rutile and possibly tourmaline.
W. F. HUNT

Chlorophaeite in the dolerites (tholeiites) of Dalmahoy and Kaimes Hills, Edinburgh. ROBERT CAMPBELL AND J. W. LUNN. *Mineralog. Mag.* 20, 435-40(1925).—These dolerites have been found to be rich in chlorophaeite, at times making up more than 15% of the rock. It is bright olive green when freshly fractured but the color changes rapidly upon exposure to dark green and finally black within 20 min. Weathered surfaces show a chocolate brown color. It occurs in vesicular cavities or in isolated groups of thin parallel veinlets. In thin section it shows green or red color, at times with minute tubular bodies resembling microorganisms. Its sp. gr. = 1.81, and it is isotropic with $n = 1.498$, probably being a colloid. Its compn. is SiO_2 32.95, TiO_2 0.62, Al_2O_3 5.40, Fe_2O_3 12.37, FeO 9.18, MnO 0.33, MgO 4.75, CaO 3.05, Na_2O 0.68, K_2O 0.36, H_2O at 105° 23.90, $\text{H}_2\text{O} + 105^\circ$ 5.20, sum 99.79%.
W. F. HUNT

Relation of texture and composition of clays. F. F. GROUT. *Bull. Geol. Soc. Am.* 36, 393-415(1925).—Twelve Minnesota clays were sepd. mechanically into 5 fractions and each was analyzed. SiO_2 tends to concn. in the sand (0.05-0.5 mm.) while Al_2O_3 , Fe_2O_3 and K_2O tend to concn. in the finer sizes (silt and clays). CaO , MgO , Na_2O and K_2O vary erratically. Kaolinite and ferric minerals are more abundant in the finer sizes; quartz and carbonates are less abundant.
W. F. HUNT

Analyses and composition of fourmarierite. J. MELON. *Ann. soc. géol. Belg.* 47, B200-2(1925).—The mineral is difficult to sep. from kasolite and torbernite, so the 3 were analyzed together and the fourmarierite was derived by subtracting the known

compus. of the others. The av. of 2 analyses is: H_2O 10.07, PbO 12.26, UO_3 77.67%, corresponding to the formula $\text{PbO} \cdot 5\text{UO}_3 \cdot 10\text{H}_2\text{O}$.

O. F. POINDEXTER

Chemical equilibrium in the formation of the German potash deposits. ERNST FULDA. *Kali* 19, 333-7(1925).—It is pointed out that the compn. of the salts crystg. from a given brine is affected by the degree of supersatn. of the brine at the time of formation of the deposit. An attempt is made to explain the origin of the various mixts. found in K salt deposits on this basis.

WM. B. PLUMMER

The influence of water on the migration of petroleum in rocks. P. FOURMARIER. *Ann. soc. geol. Belg.* 47, B192-7(1925).—Expt. shows that petroleum can pass through sand contg. water in the pellicular state and gain a higher level. If the water is in the capillary state it acts as a barrier. For intermediate stages, however, the petroleum can fill the spaces between the grains and also displace some of the water around the grains and raise it to a higher level. Reversing the position of the 2 shows that water cannot displace petroleum as rapidly as the petroleum can displace the water.

O. F. POINDEXTER

Résumé of considerations regarding the origin of petroleum. 1. P. VOITESITI. *Mon. pétrole roumain* 24, 961-70(1925).—A review of the various theories regarding the inorg. and org. origin of petroleum, with a comprehensive bibliography.

M. B. HART

Plant life as possible source of petroleum deposits. G. G. BARTTE. *Oil Weekly* 38, No. 5, 46-7(1925).—Algae, resins, spores, pollen grains, etc., contain oily substances and are abundant enough to have been the source of all petroleum resources. Older theories are discussed.

M. B. HART

Evidence of liquid immiscibility in a silicate magma, Agate Point, Ontario. T. L. TANTON. *J. Geology* 33, 629-41(1925).—The discovery in a quartz-porphry of abundant globules of glass of a compn. different from that of the main mass is pointed out as indicating the existence of immiscibility in silicate magmas.

W. F. HUNT

Basic dike injections in magmatic vein sequences. J. E. SPURR. *Bull. Geol. Soc. Am.* 36, 545-82(1925).—The following temp. scale for consolidation below the surface is suggested: 600-700°, granites and rhyolites; 500-600°, diorites, andesites, diabase, granitic pegmatites, Sn, Au-quartz, W and Ni; 400-500°, basalts, ultrabasic rocks, Cu, Zn and Pb.

W. F. HUNT

The Vermilion batholith of Minnesota. F. F. GROUT. *J. Geology* 33, 467-87(1925).—A petrographic-chem. study of the largest batholith in Minn., which reached its position by pushing aside its walls and stoping through mica schist. The main body is a biotite granite with quartz 25%, orthoclase 30, microcline 20, oligoclase 20, biotite 2, and accessories. Around the border hornblende types occur which have differentiated into syenite, shonkinite, pyroxenite and magnetite rock. Nine complete rock analyses of the various phases are recorded.

W. F. HUNT

The Giant's Range batholith in Minnesota. I. S. ALLISON. *J. Geology* 33, 488-508(1925).—A description of the structure, petrography and petrology of the Giant's Range granite and associated rocks, which occupies an area of 1000 sq. miles in north-east Minn. The batholith is a complex of intrusive rocks ranging from diabasic gabbro, hornblende, and shonkinite through monzonite and syenite to granite. Ten complete analyses are given of the various types.

W. F. HUNT

Amount of assimilation by the Sudbury norite sheet. G. W. BAIN. *J. Geology* 33, 509-25(1925).—Assuming the basal margin as representing the compn. of the original injected magma, chem. analyses show considerable variation from the base upward, which cannot be explained by magmatic differentiation. The evidence indicates a minimum assimilation of 63% in the southwest end of the basin and 67% around the eastern end. Quartzite, arkose and iron-formation may have constituted the assimilated material.

W. F. HUNT

A peculiar rock from Lower Salmien. J. ANTEN. *Ann. soc. geol. Belg.* 48, B93-4(1925).—A greenish rock, compact and with sp. gr. = 3.14, contains quartz, specular hematite, ilmenite and spessartite, the latter not in crystals but as irregular masses, indicating that the metamorphism of the rock was not complete at the time but that an intermediate stage is represented. Pressure rather than temp. is believed to have played the most important role.

O. F. POINDEXTER

Some rocks from Famennien. M. BELLIERE. *Ann. soc. geol. Belg.* 48, B69-72(1925).—A green sandstone contg. quartz, feldspars and heavy minerals has as cement mica in all stages of alteration to chlorite, giving rise to the color. A second rock nearby has the same general compn. but shows secondary growth on the quartz grains. A red sandstone, contg. rhombohedrons of calcite which are clear in the center

and impregnated with Fe compds. at the border, showed on analysis CaCO_3 34.32, FeCO_3 0.9, MgCO_3 1.12, insol. 61.29%. O. F. POINDEXTER

The rate of solution of gypsum. F. H. LAHEE. *J. Geology* 33, 548-9(1925).—The rate of soln. was detd. on a gypsum block contg. a painted inscription. In 7 yrs. the soln. of the gypsum caused the protected painted letters to acquire a relief of $1/4$ in. The annual pptn. in the region, Stonewall Co., Tex., is 23 in. W. F. HUNT

Geophysical methods for discovering water-bearing strata in subterranean salt deposits. J. KOENIGSBERGER. *Kali* 19, 353-4(1925).—Local observations of the elec. cond. of salt deposits indicate the nearness of water-bearing strata, the salt minerals in such cases being permeated with minute veins and filaments of aq. solns. which increase the cond. WM. B. PLUMMER

Brief notice of a new radioactive method of determining the age of the earth. J. H. SWARTZ. *J. Elisha Mitchell Sci. Soc.* 41, 21-2(1925).—The method depends upon the ratios U:Th and U-Pb:Th-Pb in minerals. A. L. MEHRING

The flow of solid matter, especially natural salts (RINNE) 2. Solution of concave forms upon crystals (FRIEDEL) 2.

PAWLOWSKI, AUGUSTE: *Les bauxites françaises, études géologiques, statistiques, et industrielles.* 48 pp. Paris! Librairie scientifique et générale Jules Charles et A. Brunet. Reviewed in *Le Genie civil* 87, 240(1925).

D. J. DEMOREST, R. S. WILLIAMS

French metallurgy (1889-1925) and the important part played by France in the past. ROBERT HADFIELD. *Chemistry & Industry* 44, 1029-44(1925).—Historical. E. H.

Possible improvements in metallurgical practice relating particularly to the zinc industry. GILBERT RIGG. *Bull. Inst. Mining Met.* 1925, No. 253, 12 pp.—Cost items in Zn smelting are divided into: raw material, labor and fuel, of which labor is probably the greatest. Possible direct and indirect labor-saving improvements are discussed. In the distn. process the former lie mainly in performing discharging and charging operations by mech. means and the latter in shortening of the time during which the retorts are nonproducing. Labor-saving possibilities in the electrolytic process are not as great. W. H. BOYNTON

Consumption of reagents used in flotation, 1923-24. THOMAS VARLEY. *Bur. Mines, Repts. of Investigations No.* 2709, 6 pp.(1925). E. H.

Leaching mixed copper ores with ferric sulfate; Inspiration Copper Co. G. D. VAN ARSDALE. *Trans. Am. Inst. Mining Met. Eng.* 1925, No. 1502-D, 17 pp.—A description of lab. and pilot plant expts. which led to the development of a method for leaching the mixed ores contg. chalcocite and silicates of Cu by means of solns. acidified with H_2SO_4 and carrying $\text{Fe}_2(\text{SO}_4)_3$. Fe is added to the solns. and Fe^{+++} is regenerated electrolytically to a percentage high enough to act as an efficient solvent. The decreased yield is partly compensated for by a higher c. d. A diagrammatic flow sheet of a 4500-ton leaching plant is shown. W. H. BOYNTON

Antimony and its smelting. R. JAHN. *Montan. Rundschau* 17, 565-8(1925).—The ground and dried ore is roasted, the Sb_2O_3 formed is volatilized and at once reduced in vapor form with any reducing gas. The roasting temp. must be kept at $380-420^\circ$ to keep the formation of nonvolatile oxides at a min. The material must be kept fairly dry, as any moisture regenerates Sb_2S_3 , and a calcd. amt. of air must be passed slowly over the material, whereby the ground ores are kept in rotation to present as large a surface as possible for the oxidation. Ores of 5-20% may be used. The oxidation products contain 90-93% tartaric acid-sol. Sb_2O_3 , 3.7-5.8% Sb_2O_4 and the rest as impurities. An excess of 10-15% reducing gas is necessary. The purity of the metal obtained varied with different reducing gases. Reduction with H gave a 97% metal, water gas 98.4, illuminating gas 98.29 and generator gas 96.63%. The metal appears as a very fine dust and is melted together. 0.5-1% Sb remained in the residues from roasting together with noble metals. The yield of metal as volatilized Sb_2O_3 is 93-95%. The amt. of fuel required is very small as the combustion gases can be fully utilized. The roasting process is also suitable for the production of pure Sb_2O_3 . D. T.

Equilibria in systems involving ferrous oxide. J. B. FERGUSON. *Trans. Faraday Soc.* June, 1925 (advance proof).—Attention is called to the great lack of agreement in the

results obtained by various investigators of the systems Fe-O-H and Fe-O-C . The relation of the FeO phase to these discrepancies is discussed. Fairly conclusive evidence has been presented that this phase is variable in compn. It is also believed by Eastman and Evans, and by Matsubara, that the iron phase is variable. Different investigators who do not agree on the solid phases present at equil., do agree on the numerical values of the consts., for the three-phase system. The occurrence of ferrous oxide of variable compn. may be expected to lower the temp. of transformation of FeO to Fe_3O_4 and Fe . This would account for the many futile attempts to prep. pure FeO . The evidence advanced by Eastman and Evans indicating that FeO may take up Fe in solid soln. is not conclusive, since it involves some rather large errors in the compn. of the solid phases. After a critical study of the equil. consts. found by various workers Eastman has listed the best values. The results by Chaudron and those by Ferguson differ from these by more than the probable exptl. error. At 772° the discrepancy for the ratio $P_{\text{H}_2\text{O}}/P_{\text{H}_2}$ is from 0.54 to 0.67. This may be compared to the limiting values 0.575 and 0.675 of the ratio ascribed to the iron phase by Eastman and Evans. It is suggested that these variations in the value of the ratio were due to the formation of two different ferrous oxide phases. This would also account for the diversity of the reported equil. consts. The possible formation of FeO solid solns. would make more difficult the prepn. of the most stable phase whether this be pure FeO or a given solid soln. in any given case. The formation of unstable solid solns. on either side of the stable phase might occur. In this case oxidation and reduction expts. should probably lead to the same values for the equil. consts. though the solid compns. might be quite different. It is felt that this interpretation is more in accord with metallurgical practice than is the assumption of an oxygen-bearing iron phase. D. F. MCFARLAND

The function of ferric oxide in acid and basic open-hearth slags. J. H. WHITELEY. *Trans. Faraday Soc.* June, 1925 (advance proof).—This paper discusses the action of Fe_2O_3 in carrying O from the furnace gases to the metal bath in the open-hearth. Fe_2O_3 changes at 1350° under furnace conditions to magnetic oxide which may be regarded as a compound of FeO and Fe_3O_4 . The latter is readily reduced to FeO by metallic Fe at high temps. This reaction does not proceed to completion although the equil. const. probably increases with the temp. This reduction of Fe_3O_4 by Fe enables the oxide to function as a carrier of O, since the FeO is easily oxidized again. Direct evidence of the reaction may be obtained in the acid open-hearth process during the finishing stages after the bath has dropped off the boil, especially if the iron content is above 20%. While a vigorous boil is in progress, the Fe_2O_3 in the slag remains well under 0.50%. After the C drops below 0.20% the Fe_2O_3 rises and may reach 3.0%. At the same time there is a steady rise in total Fe content of the slag. This increase must be due to transference of O from the gas to the metal by means of Fe_2O_3 . Evidently a certain amt. of dissociated FeO must exist in the molten slag, which is converted to Fe_3O_4 at the slag surface by contact with oxidizing furnace gases, and is again partly reduced to FeO by contact with the molten metal below. Fe_2O_3 thus functions as an O carrier throughout the boiling period, although accumulation of Fe_2O_3 and increase of Fe are prevented by the velocity of the C reaction and the presence, in and out of the slag, of great numbers of minute globules of Fe. Gas oxidation by agency of Fe_2O_3 greatly accelerates the removal of C. In the basic process the same effects are observed to a still greater extent. During the refining period the ratio of Fe_2O_3 to FeO is always much higher than in the acid process. Much less metallic Fe in globules is held in suspension. The presence of CaO , MgO and MnO in excess of the quantity required to satisfy the acids keeps FeO uncombined and favors its oxidation by gases. In view of the large percentage of Fe_2O_3 in the basic slag a very considerable amt. of gas oxidation should be expected; and the greater oxidizing power of a basic slag may thus be explained by the activity of its larger Fe_2O_3 content and its action as carrier of O. A fairly definite relationship exists between the percentage of Fe_2O_3 and SiO_2 and P_2O_5 , and this leads to the conclusion that the basicity of the slag is a factor upon which the Fe_2O_3 largely depends. The analyses upon which this conclusion is based are somewhat variable because of difficulties in analysis and because of variable bath conditions, such as the effect of the quantity of CO passing through the slag, temp., slag viscosity and iron content, and the vol. of air used to burn the gases in the furnace. Fe_2O_3 increases with the basicity of the slag and since gas oxidation is facilitated by presence of Fe_2O_3 in the slag, this should also increase with basicity. No definite information is available on this point but a highly basic slag will permit the complete working of a charge from a fairly high C without use of either ore or scale. D. F. MCFARLAND

Slag reactions. P. M. MACNAGR. *Trans. Faraday Soc.* June, 1925 (advance proof), cf. C. A. 19, 27.—In steel-making processes a heterogeneous system of four phases—

solid lining, liquid metal, more or less liquid slag and furnaces' gases—has to be considered. The slag is in immediate contact with the other three and there must be a tendency to form equil. with each of these. Equil. between slag and lining gives the essential difference between acid and basic practice. Intimate contact between the various constituents is necessary if rapid chem. change is to take place; hence the rate is much greater in liquid than in solid or viscous phases. Slag consisting of various oxides tends to absorb constituents from the lining and becomes more viscous, thereby setting up an "inactive" stage in the steel-making operations due to decreased rate of reaction caused by the increased viscosity. This is not necessarily a state of equil. In acid practice the slag tends to absorb SiO_2 from the banks, or similarly alter in compn. by reduction of FeO , till at about 60% SiO_2 for open-hearth temps. it becomes viscous and inactive. This compn. is practically independent of the amts. of CaO , FeO or MnO present. In basic slags, the inactive state is reached at about 60% CaO , 40% SiO_2 , and low FeO , while with increasing amts. of FeO or MnO , the SiO_2 content diminishes. The condition for stabilization of P_2O_5 in the slag is that the SiO_2 content is less than that required for the limiting slag of the same CaO , FeO content. D. F. McFARLAND

Preparation of cerium and of ferro-cerium. E. GEAY. *Rev. chim. ind.* **34**, 302-5 (1925).—Brief description of their com. manuf. A. PAPINEAU-COUTURE

Magnetic analysis needs more study. R. L. STANFORD. *Iron Trade Rev.* **77**, 555-9 (1925).—A review of the present status and possibilities of magnetic analysis of metals. J. F. BYRNE

New X-ray studies of the ultimate structures of commercial metals. G. L. CLARK, E. W. BRUGMANN AND S. D. HEATH. *Ind. Eng. Chem.* **17**, 1142-6 (1925).—The value of the monochromatic pinhole X-ray method is emphasized for ascertaining the exact condition of com. metals as regards mech. and heat treatment, grain size, and for use in testing for uniformity, establishing the relation of structure to desired properties, and developing a mfg. technic. Seventeen X-ray diagrams are reproduced as examples of the sensitiveness of the method and of the desirability of use of X-rays in industrial problems. A new multiple app. combining the pinhole and usual powder diffraction methods is shown. G. L. CLARK

Thermo-electricity of metals and alloys. J. GALIBOURG. *Rev. métal.* **22**, 400-34, 527-38, 610-30 (1925).—G. has devised a method and app. for detg. directly the curves $E = f(t)$ with short test bars (instead of wires) up to temps. above 900° , so that the samples can be subjected to uniform thermal treatment over their whole lengths. Clear curves were obtained. Production of a large no. of curves with different types of alloys showed that they are quite regular and have no singular points below 700° . An app. and method have also been devised for classifying steels according to their thermo-e m.f. (*C. A.* **16**, 2295) for distinguishing between different types of steels, and a no. of results obtained with it are given. The theoretical significance of the results obtained are discussed at considerable length. The article contains a large no. of tables and of graphs, and a bibliography of 78 references. A. PAPINEAU-COUTURE

Definition of steel and cast iron. KOTARO HONDA. *Iron Coal Trade Rev.* **111**, 450 (1925). J. F. BYRNE

Passivity of iron and other metals. A. S. RUSSELL. *Nature* **115**, 455-6 (1925).—Cr, Mn, Fe, Co and Ni show passivity. R. suggests that these elements in the active state each have 2 electrons in the 4th quantum orbit, and that the elements become passive when one of these electrons is removed to a third quantum orbit. R. prepd. and kept metals permanently in the passive state and obtained their electrode potentials by amalgamating 2 at a time in Hg and comparing their powers of reducing solns. in H_2SO_4 of various oxidizing agents. On comparing the order of the potentials of the metals in Hg with that of metals in the free state it is seen that the metals known to show passivity fall out of order. This suggests that passivity is produced and maintained when the metal is amalgamated which is consistent with Lambert's discovery that pure Fe is a noble metal when its surface is electrically neutral. The ions of these passive metals, however, do not behave as if they were ions of noble metals. With the active Fe atom having 2, 8, 14, and 2 electrons in the 1st, 2nd, 3rd and 4th quantum orbits, resp., passive Fe may be represented as having the configurations 2, 8, 15, 1 or 2, 8, 13, 8, probably the former. Metals when dissolved in Hg are far more efficient reducing agents in the presence of H_2SO_4 than when in the free state. FLORENCE N. SCHOTT

Crystallization of iron on annealing as a method of investigation of internal stresses. S. P. WOLOGDINE. *Ann. inst. polytech. Novotcherkassk (Don)* **8** (1920-22); *Rev. métal.* **22** (Extraits), 386-7 (1925).—Soft Fe which has been subjected to cold working crys-

tallizes on being annealed at a given temp., and the size of the grains increases by coalescence. W. proposes this as a method of studying the internal stresses resulting from the working of the metal.

A. PAPINEAU-COUTURE

Effect of pickling on pressed steel elastic washers. BRENIER. *Rev. métal.* 22, 568-70 (1925).—Pressed steel washers which had rusted during storage broke up on placing in acid to remove the rust. This is shown to have been due to the high tensions caused by the flattening of the but slightly annealed washers.

A. P.-C.

Some problems in connection with selection and treatment of drill steel. G. BERGSTROM AND L. NORDENFELT. *J. Chem. Met. Soc. South Africa* 26, 1-9 (1925).—There is no reliable lab. test for drill steel by means of which the quality of actual performance may be predicted. Testing by drilling against solid steel is also unsatisfactory, and drilling tests on rock are required. This should be done at a definite testing station, and a test is estd. to require 80 min. time with 20 re-sharpenings. Eleven causes of rock-drill failure are described, with their respective remedies. To reduce the tendency to break where the hardened end joins the normalized center, more drastic normalizing is advocated so that the heating when the end is hardened would not make the normalized part so weak; and the period of heating before hardening should be as short as possible. Abuse of steel in the mine and in the blacksmith shop must be avoided. Fatigue failures are described in detail, with emphasis on their gradual development from overstrained places. No remedy is possible after a crack has formed, but in the earlier stages time and heat are beneficial. These remedies are difficult to apply at a mine. A steel with max. fatigue resistance should be used, with the best compn. and structure, to be detd. by research, and it might be rested or normalized occasionally between definite periods of use. Pyrometers should be carefully used to control temp., and precautions in their use are quoted from the A. S. T. M. pamphlet A-35-24. G. F. C.

Temperature control system for dressing and tempering fishtail bits. C. H. SHAPIRO. *Bur. Mines, Repts. of Investigations No. 2712*, 18 pp. (1925).

Special nickel brasses. OLIVER SMALLEY. *Trans. Am. Inst. Mining & Met. Eng.*, Oct., 1925 (advance proof), 35 pp.—Chill-cast brasses contg. Ni and other adnns. were tested as cast, and also in some cases as forged and heat-treated, all variables except compn. being eliminated. The results are summarized in tables and excellent photomicrographs are shown. Between 1 and 4% Ni in brass gives a general improvement in properties, but more reduces the strength. Ni refines the grain-size and reduces the amt. of β -brass. Small quantities of Al increase the yield point and strength of brass, but over 3% produces weakness and brittleness. Forging may be performed between 620° and 700°, the alloys being fragile between 225° and 560°. Al increases the amt. of β -brass. Sn above 0.75% impairs the ductility of brass; 0.5% increases the yield-point and strength, and 1% may be permitted in forged brass. The tensile and shock-resisting properties are improved by 1% Fe, but more gives no improvement. Fe introduces a new constituent and refines the grain-size. The form of the grains is made more regular by Fe in cast brass and forging by causing interpenetration of the grains improves the ductility. The Al-Ni brasses are in general disappointing as the improvement in properties is not commensurate with the cost. However, the alloy with 3% Ni, 3% Al and 34% Zn is valuable for high-strength castings, being similar to Monel metal but easier to make. The brass with 3% Al was generally improved by 1% Fe, but more Fe reduced the ductility and impact strength as cast. Fe had about the same effect in Ni-Al brass, refining the grain-size. The addn. of 0.75% Sn gave a slightly higher yield point, but impaired the ductility. Pb up to 0.7% if uniformly distributed does no harm. As, Cd, Sb, Bi and especially Si, Mg, P over 0.15%, and gases are harmful impurities. A little P-Cu may be added, however, as a deoxidizer in brasses contg. Mn; otherwise a little Mn-Cu is beneficial. The details of practice in melting, fluxing, casting, gating, feeding and pouring are discussed. The alloys should be superheated from 6 to 15% for pouring, the casting temps. ranging from about 930° to 1030°.

GEO. F. COMSTOCK

Corrosion. E. C. TRAX. *J. Am. Water Works Assoc.* 14, 255-9 (1925).—A summary of existing knowledge as applied to pumps and piping.

D. K. FRENCH

Corrosion in oil refining plants. I. GINSBERG. *Ref. & Nat. Gasoline Mfr.* 4, No. 47, 40, 42 (1925).—Electrolytic corrosion of Fe which occurs with all types of oils is due to stray currents from elec. lines or from the formation of an elec. couple. Acid remaining in the refined oil together with traces of water forms an electrolyte at the bottom of the tank. $K_2Cr_2O_7$ soln. sent through the intakes with the oil prevents corrosion. $MgCl_2$ present in the brine which is found in the crude oil is the source of HCl which causes corrosion. NH_3 has been successfully used to neutralize the acidity. The best method to prevent corrosion is to remove the brine from the crude oil by dehydration.

David steel wheel and its manufacture in England. W. R. MARTIN. *J. Iron and Steel Inst.* Sept., 1925 (advance proof), 11 pp.

Welding on boilers. S. W. MILLER. *Ind. Eng. Chem.* 17, 1169(1925).—Notes as to the procedure (as regards inspection, testing, etc.) which should be followed in making boiler repairs by welding.

New galvanizing process. ANON. *Brass World* 21, 350(1925).—A nonpeeling, noncracking Zn coating on Fe wire is obtained by a process involving a preliminary treatment in a bath of molten salts before passage to the Zn bath. The structure of the coating is divisible into 3 layers: next to the Fe a solid soln. of Zn and Fe, second a layer of Zn-Fe alloys and probably a solid soln. relatively high in Zn and third, a layer of practically pure Zn. The layout is shown.

Inspecting aluminium castings with X-ray. R. J. ANDERSON. *Iron Trade Rev.* 77, 374-6(1925).—X-ray examn. is especially applicable to Al castings because of their transparency as compared to steel. A depth of 2.5 in. can be penetrated in 30 secs., with 165 kilovolts and 2 milliamps. with an intensifying screen, or in 3 min. without the screen. Defects are clearly revealed.

The arrangement of the micro-crystals in rolled Pt plate. (TANAKA) 2. Arrangement of micro-crystals in Al wire (FUJIWARA) 2. Kiln for drying and carbonizing ores (U. S. pat. 1,556,571) 1.

Cyanide solutions for treating ores. K. F. COOPER. U. S. 1,562,295, Nov. 17. A crude cyanide compd. such as prepd. from fusion of crude Ca cyanamide and NaCl, which contains CaC_2 and S in the form of sulfides, is dissolved in H_2O (to get rid of the carbide) and the soln. is aerated with a gas contg. O, e. g., with air, to change the sulfide S into thiocyanate form.

Reduction of ores. H. E. COLEY. Can. 253,802, Sept. 22, 1925. Ores or oxides are brought to a reducing temp. and liquid hydrocarbon is injected directly into or onto the mass so that the hydrocarbon comes into contact with the heated mass before the hydrocarbon decomposes and reduction is effected by the formation of nascent C.

Vanadium. A. WITTEG. U. S. 1,550,998, Aug. 25. See Brit. 215,734 (C. A. 18, 3457).

Molybdenum from ore. W. H. RIDGOUT. U. S. 1,562,125, Nov. 17. An aq. pulp of Mo ore is mixed with double its quantity of a compn. formed from H_2O 90 gals., paraffin 10 gal. soda 4 oz. and "lye" 1 lb., agitated and allowed to stand until the Mo values are sepd. by flotation.

Separating cobalt from nickel. C. G. RICHARDSON. U. S. 1,557,879, Oct. 20. Purified speisses contg. Ni, Co, As and Sb are roasted to such a point that an amt. of As equiv. to the amt. necessary for combination with the Co has been eliminated. The material may then be smelted with fluxes to produce a slag contg. the Co and a new speiss contg. the Ni, As and Sb.

Cupola furnace. A. POUMAY. Brit. 232,630, April 18, 1924. The CO produced in the melting zone is burned by a supply of secondary air introduced at a higher level. The furnace is constructed with 3 sets of tuyères.

Apparatus for refining lead or other metals. H. HARRIS. U. S. reissue 16,213, Nov. 17. See original pat. 1,465,128, C. A. 17, 3673.

Aluminothermic reduction of metals. A. PACZ. U. S. 1,562,041, Nov. 17. Material such as Fe_2O_3 and zirkite is intimately mixed and briquetted with finely divided Al above 80 mesh and the material is ignited. U. S. 1,562,042 specifies forming B-Fe alloys by briquetting material such as oxides of Fe and B with Al and igniting to effect reaction and reduction. U. S. 1,562,043 specifies castings adapted for internal-combustion engine parts, which consist mainly of Fe with 0.75-4% B, having a tensile strength of over 50,000 lbs. per sq. in.

Coating rotating molds. D. H. MELOCHE. U. S. 1,561,561, Nov. 17. The wall of a rotating cylindrical mold (such as steel molds used for casting pipe) is sand-blasted and then brushed while heated with a soln. contg. a small quantity of Na silicate with a considerable quantity of fire clay in suspension. Cf. C. A. 20, 37.

Sand cores for molding metals. W. G. THOMAS. U. S. 1,561,956, Nov. 17. Cores are formed of sand mixed with emulsified asphalt and H_2O .

Carburizing iron. N. E. PHILLIPS. U. S. 1,561,482, Nov. 17. The material to be carburized is enclosed within a mass of closely consolidated charred leather or other pulverized carboniferous substance of substantial thickness surrounded by another similarly consolidated packing of bone meal or other C-bearing substance. The material, thus packed, is heated at white heat of the enclosed Fe, for 4-10 hrs.

Iron and cement production, etc. NORSK ALUMINIUM CO., AND H. PEDERSEN. Brit. 232,930, April 23, 1924. Bauxite in lump form, diasporic or other material contg. Al_2O_3 , limestone in small lumps, finely divided Fe ore, coke and anthracite fines are smelted together in an elec. or other furnace. The aluminous slag produced may be used as the raw material for producing port. cement or the alumina may be recovered by leaching the crushed slag with warm Na_2CO_3 soln. and pptg. the alumina by CO_2 (after removing excess silica by autoclaving the soln. with lime). The Fe obtained is of low S content.

Gas furnace for heating iron, steel or other metal articles for hardening, etc. A. W. MACHLET. U. S. 1,550,911, Aug. 25.

Nonmagnetic steel wire. P. H. BRACE. U. S. 1,561,306, Nov. 10. A substantially non-magnetic ferrous alloy adapted for use in elec. meters, etc., comprises Mn 10-18, Cr 2-8, Ni 5-10, Si 0.5-5, V 0.1-1 and C 0.5-1.5%, the remainder being Fe and minor impurities.

Alloy steels. J. BERTRAM. Brit. 232,591, April 15, 1924. Alloys for cutting-tools, etc., contain Fe up to 40%, and Ni 5-40%, Cr 10-60, W 5-50, C 3% or less or B 0.2%, with or without V, U or Ta.

Alloy. J. N. EARLY. Can. 254,501, Oct. 13, 1925. An alloy contains Si 1.21, S 0.14, P 0.57, Mn 0.21, free C 1.76, combined C 1.51% and the balance Fe.

Iron-nickel-chromium alloys. R. A. HADFIELD. Brit. 232,656, Dec. 27, 1923. Fe-Ni-Cr alloys contain up to about 1% C, 0.4-8% Mn, Cr 8-25, Ni 5-17 and Si 0.7% or more, with or without W or Mo 1-10% or, in some cases, Co, V, Ti or Al up to 6%. Cf. C. 4, 19, 631.

Molybdenum and vanadium alloys. J. J. BOERCKE. U. S. 1,562,201, Nov. 17. High percentage alloys of Mo or V are produced by reducing an aluminio-thermic mixt. consisting of the Mo or V compd., e. g., Ca molybdate, the alloying metal, e. g., ferrous material, a reducing metal such as Al and a quantity of Ca(OH)_2 , fluorspar or other indifferent flux materially in excess of that for the purposes of standard aluminio-thermic practices.

Refractory oxides and alloys. T. R. HAGLUND. Brit. 232,549, April 17, 1924. Oxides such as those of Al, Mg, Cr or Zr are obtained from crude materials (which, for Al, may be bauxite, clay, alundum, firebrick, feldspar, alum, shale, lepidolite, carboniferous clay, coal dross, etc.), by fusing a mixt. of the raw material with coke, coal, charcoal or CaC_2 , a sulfide of Fe, Cu, Pb or other heavy metal or of Al, Ca, Ba, Mg or Na or a mixt. of sulfate of Ca or Ba and a sulfide. An elec. arc furnace may be used and Fe may be added if much S is present. Reducible metals and Si form an alloy which is easily separable from sulfide slag in which the refractory oxide is dissolved. The slag is cooled and treated with H_2O , acid, alkali or steam to dissolve or decompose the sulfide and leave the oxide. The cryst. product may be further purified by electrostatic or electromagnetic sepn. and treatment with acid and alkali.

Tempering light alloys. G. L. WILLIAMS. U. S. 1,562,269, Nov. 17. Alloys such as those contg. Al, Mg and Gl are immersed in a hot soln. of a salt of a heavier metal, e. g., Cu, Ni or Fe salts and the soln. while heated is subjected to the action of an electrolyzing current with the alloy as cathode until the alloy surface has taken up metal from the soln. It is then quenched in cold H_2O . This treatment serves to harden the surface of the metal.

Alloy steel tools for shaping metals. E. G. HONES. U. S. 1,561,857, Nov. 17. Tools for shaping metals in forming tubes, etc., are formed of alloy steel contg. Cu 0.1-3.0, Zr 0.1-3.0 and Co 0.1-3.0%.

Welding rod. W. F. STODDY. U. S. 1,559,015, Oct. 27. A rod adapted for use in welding is formed of Fe together with Cr 7, Mn 4 and Si 1.25%.

Welding steel rails or other metals by the thermo-aluminic process. H. GOLDSCHMIDT. U. S. 1,562,227, Nov. 17. Mech. features.

Flux for welding, brazing and tempering. G. V. IRELAND. U. S. 1,562,330, Nov. 17. A dry mixt. contg. powd. borax 85, Fe carbonate 12.5 and NaHCO_3 2.5%.

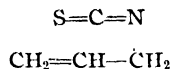

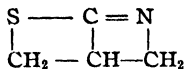

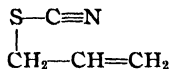

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

History of stereochemistry. B. RASSOW. *Naturwissenschaften* 13, 819(1925).—Reply to Ernst Cohen (C. A. 19, 3178).

Transformation of thiocyanates into mustard oils. B. J. C. VAN DER HOEVEN. O. BILLETER. *Helvetica Chim. Acta* 8, 337-8(1925).—It is suggested that when an unsatd. thiocyanate changes

to a mustard oil the process involves a shift of the double bond and the C atom at the other end of the chain:

If this is true then thiocyanates of the formula $\text{CNSCH}_2\text{CH}:\text{CHR}$ would give mustard oils with a different though isomeric radical, $\text{SCNCH}_2\text{CH}:\text{CHR}$. It was found that cinnamyl thiocyanate, $\text{PhCH}:\text{CHCH}_2\text{SCN}$ does not isomerize to a mustard oil when heated but decomps. If only the SCN group were involved it would not be expected that the Ph group would prevent the change and the above fact is negative evidence for the theory. Work still incomplete indicates that crotonyl thiocyanate, $\text{NCSCNCH}:\text{CHMe}_2$, gives a mustard oil with a different radical, as expected from the theory.

Diallylcyanamide. E. B. VLIET. *Organic Syntheses V*, 45-7(1925) — Na_2NCN (prepd. from CaNCN and NaOH) is treated with $\text{CH}_2:\text{CHCH}_2\text{Br}$, giving 52-6% $(\text{CH}_2:\text{CHCH}_2)_2\text{NCN}$. M. A. YOUTZ

Nitrourea. A. W. INGERSOLL AND B. F. ARMENDT. *Organic Syntheses V*, 85-6 (1925).— $\text{CO}(\text{NH}_2)_2$, HNO_3 , added to concd. H_2SO_4 at -3° to 0° , gives 70-87% of $\text{H}_2\text{NCONHNO}_2$. C. J. WEST

Semicarbazide sulfate. A. W. INGERSOLL, L. J. BIRCHER AND M. M. BRUBAKER. *Organic Syntheses V*, 93-7(1925).—Directions are given for the electrolytic reduction of $\text{H}_2\text{NCONHNO}_2$ in H_2SO_4 , the yield of $\text{H}_2\text{NCONHNH}_2 \cdot \text{H}_2\text{SO}_4$ being 61-94%. C. J. WEST

Creatinine. GRAHAM EDGAR AND W. S. HINEGARDNER. *Organic Syntheses IV*, 15-7(1925).—Com. creatine hydrate (I) is warmed with dil. HCl for 24 hrs and then treated with NH_3 , giving 80-1% of creatinine. I, heated with ZnCl_2 to fusion, gives 76-8% of creatinine- ZnCl_2 . The product of heating I and HCl , treated with picric acid, gives 89-90% of the picrate. C. J. WEST

Velocity of the oxidation of sugars by permanganate. RICHARD KUHN AND THEODOR WAGNER-JAUREGG. *Ber.* 58B, 1441-7(1925); cf. *C. A.* 19, 1649.—In the literature of recent years are many papers on the behavior of carbohydrates and related compounds towards KMnO_4 , from which it would seem that the γ -sugars are especially reactive. These conclusions, however, are based on qual. observations which may easily lead to errors if the exptl. conditions are not carefully controlled. It is not sufficient to make expts. with a few drops of very dil. KMnO_4 when there is no guarantee of the abs. purity of the substance in question. K. and W.-J. have devised a quant. method, based on titration of the KMnO_4 in solns. kept at an approx. const. small acidity by means of phosphate mixts. The more important sugars are characterized by the "permanganate reaction time" (*pri*), i. e. the time in min. required by 5.00 g. hexose or the equiv. amt. of pentose or disaccharide to reduce to 25% 20 cc. of 0.1 N KMnO_4 in 100 cc. of 0.04 N $\text{KH}_2\text{PO}_4\text{-H}_3\text{PO}_4$ mixt. (1:1) at 18° . These values for α, β -equil. solns. are: maltose 9.0, fructose 9.5, arabinose 10.0, galactose 13.5, lactose 34.0, mannose 21.0, glucose 30.5. The β -sugars react more rapidly than their α -isomers, the $\alpha:\beta$ -*pri* for glucose, galactose and mannose being about 1.7:1, for lactose (5.0% soln. at 20.5°) 1.25:1. In the case of fructose, no difference greater than the exptl. error could be detected in the *pri* of the β - and the α, β -forms. With fructose at varying degrees of acidity a min. in *pri* is found at pH = about 4; the curve previously obtained by the decolorization method could not be confirmed by the new titration method. On testing by the new method the observation of Haworth and Law that fructose in pure H_2O does not reduce KMnO_4 unless it has first been allowed to stand for some time in acid soln. and then treated with KMnO_4 after neutralization it was found that the *pri* at a const. pH is independent of whether or not the fructose has previously been exposed to an acid. On the other hand, Armstrong's and Hilditch's statement that a sugar soln. reacts more rapidly with KMnO_4 if it has previously been allowed to stand in alk. soln. has been confirmed; this cannot be ascribed to the establishment of the equil. between fructose, glucose and mannose, for fructose, the sugar which reacts most rapidly with KMnO_4 , likewise shows increased reactivity after treatment with a dil. alkali. If the phenomenon were due exclusively to the formation of enol mols. of the sugar, as believed by A. and H., the *pri* of the neutralized soln. would be expected gradually to return to the normal value, but as a matter of fact on standing there is only a slight increase of the *pri* (about $1/6$ of the decrease produced by the alkali). Sucrose solns. quickly hydrolyzed with saccharase showed, after interruption of the enzyme action, only a slight decrease in *pri*, whence K. and W.-J. conclude that either there is no difference in the *pri* between ordinary

fructose and that form of it contained in sucrose or that the rearrangement of the latter form is so rapid that its intermediate formation cannot be detected. In carrying out the velocity measurements, 10-cc. portions of the reaction mixt. are poured at definite time intervals into 15 cc. of a $M/15$ $\text{KH}_2\text{PO}_4\text{-H}_3\text{PO}_4$ mixt. (1:1) + 1 cc. of 10% KI and the liberated I is titrated with 0.02 N $\text{Na}_2\text{S}_2\text{O}_3$. C. A. R.

Glycose or glucose. EDMUND O. VON LIPPIMANN. *Z. angew. Chem.* **38**, 631 (1926).—A discussion of the etymology of the words, preferring glycose to glucose. M. A. Youtz

New methyl derivatives of *d*-glucose. EUGEN PACSU. *Ber.* **58B**, 1455-64 (1925); cf. *C. A.* **18**, 3044.—Condensations of *d*-glucose dibenzyl mercaptal (I) with MeCOEt analogous to those previously carried out with Me_2CO have been effected. Owing to the slight soly. of the I in MeCOEt the condensation proceeds very slowly and the mixt. of mono- and diketone mercaptals in the sirupy reaction product is much more difficult to sep. than that obtained with Me_2CO ; the mono compd. (II) can be isolated only in small amt. No solid PhSO_2 deriv. of the diketone compd. (III) can be obtained but methylation of the mixt. proceeds as smoothly as with the Me_2CO compds.; the ketone residues can be rapidly split off from the methylated derivs. with HCl , the products being identical with those obtained from the Me_2CO compds. The mono-Me deriv. (IV) of I treated in abs. EtOH with more than 2 mols HgCl_2 (cf. *C. A.* **19**, 2056), yields $2\text{PhCH}_2\text{SHgCl} + 2\text{HCl} +$ a methylglucose Et glucoside (V). The V need not be isolated; it can be hydrolyzed directly with dil. HCl to a methylglucose (VI) differing entirely from the 3 known methylglucoses with a hydrofuran ring. The tri-Me deriv. (VII) of I with 2 mols HgCl_2 in abs. MeOH likewise yields a trimethylglucose Me glucoside (VIII) easily hydrolyzed by HCl to a trimethylglucose (IX), a thick sirup drying *in vacuo* to an easily pulverized mass which, however, soon changes again to a thick sirup in the air. IX, which is undoubtedly a mixt. of the α - and β -forms, yields an osazone, showing that the HO group on the 2-C atom is not methylated and hence that II must be the 2,3 ketone compd. and that the 2nd ketone residue in III can be attached only through the HO groups on C atoms 4 and 5 or 5 and 6, and since the VI differs entirely from Helferich and Becker's 6-methylglucose (*C. A.* **19**, 250) III must be the 2,3,5,6-diketone compd. and VI a 4-methylglucose. (If the H and B compd. should really be a 5-methylglucose, a possibility which has not been entirely excluded, VI might be a 6-Me deriv., but its great instability towards KMnO_4 and its striking optical properties all indicate that it is not of the furoid type, an assumption which would be quite arbitrary and contrary to all previous experience if it were a 6 Me deriv.) When IX, which must be a 4,5,6 trimethylglucose, is acetylated in the usual way with the aid of concd. H_2SO_4 it yields an oily product which no longer reduces Fehling soln. and must therefore be 1,2-monoacetone-4,5,6-trimethyl-*d*-[1,3]-glucose; hence IX is in all probability a deriv. of the unknown [1,3]-glucose. VI can also not belong to the furoid type, but as it forms no condensation product with Me_2CO it is not possible as yet to det. which of the 4 possible non-furoid structures it has. Degradation of IV and VII with only 1 mol. HgCl_2 yields methylated thioglucosides, the product from VII is oily but that (X) obtained from IV is a well crystd. substance showing no mutarotation and is provisionally assigned a [1,5]-glucose structure. 2,3-Monomethylethylketone-*d*-glucose dibenzyl mercaptal (II) (0.5 g. from 10 g. I), m. 90 $^{\circ}$, $[\alpha]_D^{15}$ -6.56° in $(\text{CHCl}_3)_1$, -117.58° in alc. The cor. m. p. of VII, previously given as 73 $^{\circ}$, is 96 ; on very low concn. of its alc. soln. at room temp. it may be obtained in very large crystals (weighing over 1 g.), either monoclinic-prismatic hexangular tables or long rhombic-bipyramidal columns. 4-Methyl- β (?)-*d*-[1,5(?)]-glucose (VI) (2.8 g. from 8.48 g. IV), begins to sinter 149 $^{\circ}$, m. 156-7 $^{\circ}$, is faintly sweet, shows mutarotation in H_2O ($[\alpha]_D^{15}$ 18.57 $^{\circ}$ 3 min. after soln., 61.92 $^{\circ}$ (final value) after 4 hrs.), and in alc. ($[\alpha]_D^{15}$ 32.44 $^{\circ}$ (initial), 52.58 $^{\circ}$ (final, after 52 hrs.)); the change in rotation proceeds according to the equation for a bimol. reaction, the mean k at 15 $^{\circ}$ in H_2O being 0.01935. The reversibility of the process is shown by the fact that the sirup obtained from the evapd. soln. slowly changes into a cryst. mass having the original rotation. The apparently bimol. course of the mutarotation may possibly be due to a shifting of the O bridge with the simultaneous formation of the α - and β -forms. In H_2SO_4 VI reduces KMnO_4 about 6 times as rapidly as glucose under the same conditions. Osazone, yellow, decomps. 198 $^{\circ}$ on rapid heating (1 $^{\circ}$ in 7 sec.), 192-3 $^{\circ}$ on slower heating (1 $^{\circ}$ in 15 sec.), shows mutarotation in $\text{C}_6\text{H}_5\text{N}_3\text{N}_3\text{O}_2\text{H}$ ($[\alpha]_D^{15}$ -50.33° (initial), -34.84° (final, after 19 hrs.)). 4,5,6-Trimethyl-*d*-[1,3] glucose (IX), $[\alpha]_D^{15}$ 75.81 $^{\circ}$ (alc.), shows no mutarotation in alc. but shows it in H_2O ($[\alpha]_D^{15}$ 65.94 $^{\circ}$ (initial), 61.13 $^{\circ}$ (final, 4 hrs.)); osazone, yellow, m. 156-7 $^{\circ}$, $[\alpha]_D^{15}$ -32.63°

(initial), —15.46° (final, 21 hrs.) in alc. 4-Methyl- α -benzylthio-[1,5(?)]-glucoside (X) (0.76 g. from 2.12 g. IV), m . 136°, $[\alpha]_D^{15}$ 249.61° (alc.). C. A. R.

Preparation of raffinose from cottonseed meal. D. T. ENGLIS, R. T. DECKER AND A. B. ADAMS. *J. Am. Chem. Soc.* **47**, 2724–6 (1925).—A modification of Ritt-hausen's extn. of raffinose from cottonseed meal, using MeOH instead of EtOH to effect a saving in solvent, is described. The crystn. of the raffinose from the ext., following the directions of Hudson and Harding (*C. A.* **8**, 3777) for crystg. from purified raffinose solns., can be made directly with the yield obtained by them (2.5% of pure recrystd. sugar). C. J. WEST

Molecular coefficients of refraction in the series of polymethylene compounds. FRITZ EISENLOHR. *Fortschritte der Chemie, Physik, physikal. Chem.* **18**, 521–66 (1925).—The values given below after the b . p. arc, resp. $d_4^{20_{vac}}$, and n for α , He, β and γ at 20°. Cyclopentane, b_{755} 50°, 0.7510, 1.40383, 1.40609, 1.41126, 1.41536. Methylcyclopentane, b_{755} 70–70.5°, 0.7459, 1.40750, 1.40947, 1.41465, 1.41868. Ethylcyclopentane, b_{755} 100.5–1°, 0.7610, 1.41612, 1.41840, 1.42332, 1.42798. Propylcyclopentane, b_{754} 129.5°, 0.7718, 1.42285, 1.42470, 1.43040, 1.43474. The *m*-deriv. b_{755} 170.5°, 0.9182, 1.44270, 1.44526, 1.45122, 1.45598. The *p*-deriv. b_{755} 171.5°, 0.9128, 1.44099, 1.44346, 1.44924, 1.45401. Values recorded by other observers are given and the interrelationships of the values discussed. C. J. WEST

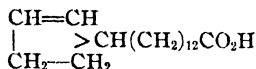

Synthesis and reactions of 1-anilino-cyclopentane-1-carboxylic acid. S. G. P. PLANT AND J. E. FACER. *J. Chem. Soc.* **127**, 2037–40 (1925).—The $NaHSO_4$ compd. of $(CH_3)_2CO$ was treated with HCN, the cyanohydrin extd. with C_6H_6 , treated with $PhNH_2$ and boiled for 12 hrs. and the excess $PhNH_2$ extd. with dil. HCl, giving 1-anilino-1-cyanocyclopentane, m . 58°, decomp. on distn. Cold H_2SO_4 gives the amide, m . 161°. Nitrosamine, m . 122°, of 1-anilino-cyclopentane-1-carboxylic acid, m . 162° (nitrosamine, m . 124° (decompn.)). On heating the acid at 230°, it decomp., giving $PhNH_2$ and

H₂O and the lactone of 1,1'-hydroxycyclopentane-1'-carboxylanilino-cyclopentane-1-carboxylic acid, (CH₂)₄:C.CO.O.C[: (CH₂)₄].CO.NPh, m. 142° (*Ac deriv.*, m. 195°).

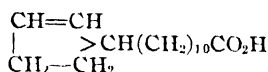

Heating the acid with EtONa and KOH at 270–320° gave some carbazole but not the expected ψ -indoxylspirocyclopentane.

Cyclopentanone. J. F. THORPE AND G. A. R. KON. *Organic Syntheses V*, 37–8 (1925).—HO₂C(CH₂)₄CO₂H, heated with crystd. B₂(OH)₂ at 285–95°, gives 75–80% of cyclopentanone.

Structure of chaulmoogric and hydnocarpic acids. I. R. L. SHRINER AND ROGER ADAMS. *J. Am. Chem. Soc.* **47**, 2727–39 (1925); cf. Power and Gornall, *J. Chem. Soc.* **85**, 838, 851 (1904); Barrowcliff and Power, *Ibid* **91**, 557 (1907).—The formula for chaulmoogric acid (I) is discussed in the light of Power's work and shown to be I; hydnocarpic acid (II) is II. I (14 g.) in 200 cc. 95% EtOH is reduced to the dihydro deriv. in 1 min. by 0.1 g. Pt oxide catalyst at 2–3 atms. II is reduced equally readily, the dihydro acid m. 6.4–5°. Me dihydrochaulmoograte, b₁₀ 204–5°, m. 27°, d₂₅²⁰ 0.9018, n_D³⁰ 1.4536 *Me dihydrohydnocarpate*, b₁₀ 187–8°, d₂₅²⁰ 0.9057, n_D³⁰ 1.4523. I and 31% HBr in glacial AcOH, warmed at 100°, for 1 hr., give bromodihydrochaulmoogric acid, m. 37–8°; refluxed with 2.5 mol. equivs. of EtOH-KOH, a mixt. of acids contg. 22% I was regenerated, with α_D 13.8°. Oxidation of isochaulmoogric acid by KMnO₄ gives pentadecane- γ -keto- α,α' -dicarboxylic acid, m. 125–6°, which is reduced by amalgamated Zn and 10% HCl to hexadecane- α,α' -dicarboxylic acid, m. 118°, which was also prepd. by the electrolysis of K Et sebacate. O₃ and I in glacial AcOH give a glassy pentadecane- α,γ -dialdehyde- α' -carboxylate (III), analyzed as the NH₄ salt, which is oxidized by Cr₂O₃ to pentadecane- α,α',γ -tricarboxylic acid, whose tri-Me ester, m. 37–8°, was prepd. by Power. O₃ and the Me ester of I gave the Me ester of III, whose dioxime m. 93–4°; another sample m. 102–3° (there are 4 possible isomers).

(II)

C. J. WEST

Formation and stability of associated alicyclic systems. II. The formation and disruption of dicyclic dihydroresorcinols. E. H. FARMER AND JOHN ROSS. *J. Chem. Soc.* **127**, 2358–69 (1925); cf. C. A. **14**, 2620—1-Methyl- Δ^1 -cyclohexen-3-one (I), b. 199–202°, condensed with CHNa(CO₂Et)₂ by heating 16 hrs. at 100°, gives about 10% of red oils giving purple colors with FeCl₃, 65% of Et β -methylpimelate- β -acetate (II), b₁₈ 200°, the remainder consisting principally of III. Hydrolysis of II gives the free acid, m. 123–4°; heating with excess AcCl for 15 hrs. gives an anhydro acid, m. 83°; Et ester, b₁₈ 200°. Condensation at room temp. gave Et 1-methylcyclohexan-3-one-4-carboxylate-1-acetate (III), b₁₈ 182° and gives a deep purple color with FeCl₃. Hydrolysis with HCl gives 1-methylcyclohexan-3-one-1-acetic acid, b₁₅ 196°, m. 37°; semicarbazone, m. 189°; Ag salt; Et ester (IV), b₁₅ 147°, whose semicarbazone, m. 158–9°. The presence of Et ethane-1,2-di-*II*^{1,4}-1-methylcyclohexa-3,5-dione-2-carboxylate (V) was probably responsible for the resinous material obtained on hydrolysis of the ester mixt.; boiling with EtOH-EtONa gave II. Intramol. condensation of II by heating with Na in C₆H₆ or PhMe gave 75% of III; some V, b₁₈ 190–200°, m. 111°, gives a deep color with FeCl₃ after 10 min.; some Et H ester corresponding to III, m. 91°, gives an immediate color with FeCl₃. No definite products were obtained from IV. Oxidation of III with 3% KMnO₄ gives MeC(CH₂CO₂H)₃, m. 172°. Oxidation of the mixt. from the condensation of IV gives β -methyladipic- β -acetic acid, m. 148–9°, whose ester imide, m. 169°; this is also obtained from Et levulate, CNCH₂CO₂Et and alc. NH₃. β -Methylpimelic- β -acetic acid, m. 124–5°, was likewise synthesized from AcCH₂CH₂CH₂CO₂Et through the ester imide, m. 138–9°.

C. J. WEST

***o*-Chlorocyclohexanol.** G. H. COLEMAN AND H. F. JOHNSTONE. *Organic Syntheses V*, 31–2 (1925).—Cyclohexene reacts with HOCl (prepd. by passing Cl into a cold soln. of HgCl₂ and NaOH, finally adding HNO₃) to give 70–3% *o*-chlorocyclohexanol.

C. J. WEST

Cyclohexene. G. H. COLEMAN AND H. F. JOHNSTONE. *Organic Syntheses V*, 33–4 (1925).—Cyclohexanol and concd. H₂SO₄, distd. at 130–40°, give 78–87% cyclohexene.

C. J. WEST

Cyclohexene oxide. A. E. OSTERBERG. *Organic Syntheses V*, 35–6 (1925).—*o*-Chlorocyclohexanol and aq. NaOH give 70–3% cyclohexene oxide.

C. J. WEST

Interaction of ethyl acetoacetate and *o*-hydroxydistyryl ketones. II. I. M. HEILBRON, T. A. FORSTER AND A. B. WHITWORTH. *J. Chem. Soc.* 127, 2159–67(1925); cf. *C. A.* 19, 484.—The present work definitely proves that, in all cases examd., cyclohexenones alone are formed as products of the condensation. $\text{AcCH}_2\text{CO}_2\text{Et}$ and $o\text{-HOC}_6\text{H}_4\text{CH:CHCOCH:CHC}_6\text{H}_4\text{NMe}_2\text{-}p$, condensed by EtOH-KOH at room temp. give *Et 3-*p*-dimethylaminophenyl-5-*o*-hydroxystyryl- Δ^6 -cyclohexen-1-one-2-carboxylate* (I), orange-yellow, m. 196° and crystg. with 1 mol. EtOH or C_6H_6 ; the constitution is established by oxidation with KMnO_4 , giving $o\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$. Heating with NaOH gives the free acid, yellow, m. 225° , which, boiled with 20% H_2SO_4 in AcOH , gives *3-*p*-dimethylamino-5-*o*-hydroxystyryl- Δ^6 -cyclohexen-1-one*, yellow, m. 232° . Methylation in Me_2CO gave the *5-*o*-MeO deriv.* (II) of I, lemon-yellow, m. 164° , giving a yellow soln. in EtOH-KOH and red in concd. H_2SO_4 . *Et 3-*o*-methoxyphenyl-5-*p*-dimethylaminostyryl- Δ^6 -cyclohexen-1-one-2-carboxylate* (III), orange, m. 114° , extremely hygroscopic; traces of II also are formed. III in EtONa , heated with MeI for 2 hrs., gives *Et 1-methoxy-3-*o*-methoxyphenyl-5-*p*-dimethylaminostyryl- $\Delta^{1,6}$ -cyclohexadiene-2-carboxylate*, pale yellow, m. 148° . *Et 3-*p*-dimethylaminophenyl-5-*p*-dimethylaminostyryl- Δ^6 -cyclohexen-1-one-2-carboxylate*, orange-yellow, m. $174\text{--}5^\circ$; *phenylhydrazone*, m. 239° . *Et 3-*p*-dimethylaminophenyl-5-methylcyclohexan-5-ol-1-one-2-carboxylate*, m. 149° , from $\text{AcCH}_2\text{CO}_2\text{Et}$ and $\text{MeCOCH:CHC}_6\text{H}_4\text{NMe}_2$; *phenylhydrazone*, m. 179° . The corresponding cyclohexenone, m. 66° , results upon heating with 10% NaOH . *Et 3-*p*-dimethylaminophenyl-5-[3'-methoxy-2'-hydroxy]styryl- Δ^6 -cyclohexen-1-one-2-carboxylate* (IV), yellow, m. $197\text{--}8^\circ$. *3-[4'-Methoxy-2'-hydroxy]phenyl-5-*p*-dimethylaminostyryl- Δ^6 -cyclohexen-1-one*, orange-red, m. 218° . The [5'-methoxy-2'-hydroxy] deriv corresponding to IV, yellow, with 1 C_6H_6 , m. $196\text{--}7^\circ$. Crystn. from aq. $\text{C}_6\text{H}_6\text{N}$ gives *3-[5'-methoxy-2'-hydroxy]phenyl-5-*p*-dimethylaminostyryl- Δ^6 -cyclohexen-1-one*, orange, m. 250° . With $\text{NCCH}_2\text{CO}_2\text{Et}$ and $o\text{-HOC}_6\text{H}_4\text{CH:CHCOCH:CHC}_6\text{H}_4\text{NMe}_2\text{-}p$, there results γ -*p*-dimethylaminocinnamyl- β -*o*-hydroxyphenylpropane- α,α' -dicarboxylic acid, orange, m. 220° .

C. J. WEST

Constitution of benzene and the substitution process in the benzene nucleus. MICHELE GUÀ AND RODOLFO PETRONIO. *J. prakt. Chem.* 110, 289–308(1925); cf. *C. A.* 18, 2874.—The effects of various substituents on the lines of force in the C_6H_6 mol. are discussed and illustrated by typical reactions. $2,4\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{Cl}$ and H_2NCN give the light yellow *2,4-dinitrophenylcyanamide*, m. $168\text{--}9^\circ$; dissolved in fuming HNO_3 and pptd. with H_2O , there results *2,4-dinitrophenylnitrourea*, yellowish red, m. $146\text{--}7^\circ$ (decompn.); EtOH-HCl gives nearly quant. $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{NHCNHNH}_2$, m. 178° . *4,6-Dinitro-m-tolylcyanamide*, Au-yellow, m. $161\text{--}2^\circ$; concd. HCl gives *4,6-dinitro-m-tolylurea*, pale yellow, m. $205\text{--}6^\circ$ (decompn.); fuming HNO_3 gives the *nitro deriv.*, yellow m. $168\text{--}9^\circ$ (decompn.). *2,4-Dinitro-m-tolylurea*, pale yellow, m. $224\text{--}5^\circ$. *2,4,6-Trinitrophenylsemicarbazide* (*purylsemicarbazide*), yellow, m. $218\text{--}9^\circ$ (decompn.); the corresponding *semioxamamide*, yellow, m. $249\text{--}50^\circ$ (decompn.). β -Trinitrotoluene and PhCH-NEt give *2,4-dinitro-m-ethyltoluidine*, m. $68\text{--}9^\circ$; the γ -deriv. gives the *4,6-dinitro deriv.*, yellow, m. $125\text{--}6^\circ$. *2-Ethylamino-3,5-dinitro-*p*-toluic acid*, light yellow, m. $190\text{--}1^\circ$. *2,4-Dinitropropyl-m-toluidine*, light yellow, m. $64\text{--}5^\circ$; the *4,6-dinitro deriv.*, yellow, m. $106\text{--}7^\circ$. *4,6-Dinitro-m-isoamyltoluidine*, yellow, m. $87\text{--}8^\circ$. C. J. W.

Mesitylene. ROGER ADAMS AND R. W. HUFFERD. *Organic Syntheses II*, 41–5 (1922).—About 13–15% of $\text{C}_6\text{H}_3\text{Me}_3$ is obtained from Me_2CO and concd. H_2SO_4 .

C. J. WEST

Propylbenzene. HENRY GILMAN AND C. H. MEYERS. *Organic Syntheses IV*, 59–61(1925).— PhCH_2MgCl and Et_2SO_4 give 55–65% PrPh .

C. J. WEST

Phenylacetylene. J. C. HESSLER. *Organic Syntheses II*, 67–9(1922).— PhCH:CHBr and KOH at 200° give 67% of PhC:CH .

C. J. WEST

***o*- and *p*-Chlorotoluenes.** C. S. MARVEL AND S. M. McELVAIN. *Organic Syntheses III*, 33–5(1923).— $o\text{-H}_2\text{NC}_6\text{H}_4\text{Me}$, diazotized and treated with CuCl , gives 74–9% $o\text{-ClC}_6\text{H}_4\text{Me}$. The *p*-deriv. is obtained similarly in 70–9% yields.

C. J. WEST

***p*-Bromotoluene.** L. A. BIGELOW. *Organic Syntheses V*, 21–2(1925).—Diazotized $p\text{-MeC}_6\text{H}_4\text{NH}_2$, treated with HBr and CuBr , gives 70–3% $p\text{-BrC}_6\text{H}_4\text{Me}$.

C. J. WEST

The reduction of nitro derivatives by calcium hydride. J.-F. DURAND AND SHERILL HOUGHTON. *Compt. rend.* 180, 1034–6(1925).— MeNO_2 (I), in cold Et_2O with powd. CaH_2 (II) gives 1 mol. of H per mol. of I, and the salt $(\text{CH}_3\text{NO})_2\text{Ca}$. If II is boiled with PhNO_2 in ligroin (b. $75\text{--}95^\circ$) green vapors are given off and these condense to a green liquid contg. PhNO (III). But if the mixt. is refluxed for 2 hrs. azoxybenzene (IV) is formed. If III is likewise refluxed, IV is formed. IV is not affected by II in 5 hrs. of refluxing.

M. A. YOUTZ

1,3,5-Trinitrobenzene. H. T. CLARKE and W. W. HARTMAN. *Organic Syntheses* II, 93-4(1922).—Crude $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$ is neutralized with NaOH, glacial AcOH added and the mixt. heated, giving 43-6% of 1,3,5- $\text{C}_6\text{H}_3(\text{NO}_2)_3$ (calcd. on the $(\text{O}_2\text{N})_3\text{-C}_6\text{H}_2\text{Me}$). C. J. WEST

***m*-Nitrochlorobenzene.** W. W. HARTMAN and M. R. BRETHEN. *Organic Syntheses* III, 79-81(1923).— $\text{m-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ is diazotized and treated with CuCl, giving 68-71% $\text{m-O}_2\text{NC}_6\text{H}_4\text{Cl}$. C. J. WEST

***m*-Nitrotoluene.** H. T. CLARKE and E. R. TAYLOR. *Organic Syntheses* III, 91-3(1923).—The diazo compd. from 3,4- $\text{O}_2\text{N}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{NH}_2$ is decompd. by EtOH, giving 67-77% of $\text{m-O}_2\text{NC}_6\text{H}_4\text{Me}$. C. J. WEST

Influence of nitro groups on the reactivity of substituents in the benzene nucleus.

VIII. **2,3- and 2,5-Dinitro-*p*-chlorotoluenes.** JAMES KENNER, C. W. TOD and ERNEST WITAM. *J. Chem. Soc.* 127, 2343-9(1925); cf. *C. A.* 17, 2567.—Nitration of 4,2- $\text{Cl}(\text{AcNH})\text{C}_6\text{H}_3\text{Me}$ in $\text{AcOH-H}_2\text{SO}_4$ by fuming HNO_3 and hydrolysis give a mixt. of 4-chloro-5-nitro-*o*-toluidine, m. 163-4° (*Ac* deriv., m. 181-2°), reduced by SnCl_2 and HCl to 5-chloro-2-methyl-*p*-phenylenediamine, m. 145-6° (*Ac* deriv., m. 301°); and the 3-nitro deriv., light brown, m. 60-62.5° (*Ac* deriv., m. 194-5°). 4-Chloro-6-nitro-*o*-toluidine (I), yellow, m. 120-1° (*Ac* deriv., m. 134-5°). The isomeric 2-nitro deriv. (II), lemon-yellow, m. 52-3° (*Ac* deriv., m. 210-2°). I was converted through the diazo compd. to the 4,5,2- $\text{Cl}_2(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{Me}$, which, with MeOH and Na, yields 4-chloro-6-nitro-*m*-tolyl Me ether (III), straw-colored, m. 121-2°. 4-Chloro-2,3-dinitrotoluene, lemon-yellow, m. 106.5°; MeOH- NH_3 for 8 hrs. at 140-50° gives II. MeOH- NH_3 and 4,2,5- $\text{Cl}_3(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{Me}$, heated at 160° for 16 hrs., then extd. by boiling concd. HCl, gave III, a small amt. of the corresponding cresol and I. MeONa gives III nearly quant. In all these cases the group that is displaced is that in the *m*-position to the Me group rather than that in the *m*-position to the Cl atom. C. J. WEST

Benzalaniline. M. T. BOGERT. *Organic Syntheses* V, 13-4(1925).—One mol. each of BzH and PhNH_2 , heated at 125° for 5 hrs., give 85-6% PhCH:NPh . C. J. W.

Phenylurea. T. L. DAVIS and K. C. BLANCHARD. *Organic Syntheses* III, 95-7(1923).— PhNH_2 , HCl and $\text{CO}(\text{NH}_2)_2$, boiled for about 2 hrs., give 52-5% PhNHCONH_2 and 38-40% $(\text{PhNH})_2\text{CO}$. C. J. WEST

A rapid method for the preparation of thiocarbamilide. S. J. C. SNEDKER. *J. Soc. Chem. Ind.* 44, 486T(1925).—To a mixt. of 372 g. of PhNH_2 and 380 g. CS_2 , 400 cc. of 40% NaOH is added with cooling and agitation. H_2O is added to make the mixt. more fluid, and the $(\text{PhNH})_2\text{CS}$ is filtered, washed and dried. T. S. C.

Velocity of benzylation of certain amines. II. D. H. PEACOCK. *J. Chem. Soc.* 127, 2177-80(1925); cf. *C. A.* 19, 766.—The following velocity coeffs. in MeOH for PhCH_2Cl , $\text{m-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Cl}$ and $\text{p-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Cl}$ are reported at 35° and 45°: PhNH_2 , 0.00368, 0.00185, 0.0144, 0.0092, 0.00451, 0.00365. $\text{p-MeC}_6\text{H}_4\text{NH}_2$, 0.00596, 0.00407, 0.00276; 0.0147, 0.00874, 0.00667. $\text{o-MeC}_6\text{H}_4\text{NH}_2$, 0.00269, 0.00123, 0.000832; 0.00596, 0.00256, 0.00207. PhNMe_2 , 0.00278, 0.000671, 0.000404; 0.00609, 0.00132, 0.00092. In all cases the concn. of the base was 0.8 *M*, of the chloride, 0.2 *M*. Data for 0.2 *M* PhCH_2Cl and the following bases also are reported: $\text{m-MeC}_6\text{H}_4\text{NH}_2$, 0.8 *M*, 35°, 0.00494; $\text{m-O}_2\text{NC}_6\text{H}_4\text{NH}_2$, 0.8 *M*, 45°, 0.00168; $\text{p-O}_2\text{NC}_6\text{H}_4\text{NH}_2$, 0.4 *M*, 45°, 0.0002; PhNHMe , 0.8 *M*, 35°, 0.00644; 45°, 0.0187; PhNHCH_2Ph , 0.8 *M*, 45°, 0.00335; $\text{p-BrC}_6\text{H}_4\text{NMe}_2$, 0.8 *M*, 45°, 0.00175. The introduction of a NO_2 group into the nucleus of the base considerably reduces the reaction velocity. The effect of concn. on the velocity coeffs. and energies of activation depends on the character of the base employed. It is suggested that the formation of a loose mol. complex precedes activation and the energy of activation measured in the cases cited is the energy of activation of such a complex. C. J. WEST

Reactions of azoxy compounds. I. The action of light. WM. M. CUMMING and G. S. FERRIER. *J. Chem. Soc.* 127, 2374-9(1925).—Azoxybenzene, exposed to ultra-violet light, gives the *o*-HO deriv., m. 82-3°; the yields (% of the *o*-HO deriv. after 50 hrs. illumination) obtained with various solvents were: 85% EtOH, 20.5; 100% EtOH, 28.0; MeOH, 24; PrOH, 26.3; C_6H_6 , 7.7; boiling EtOH, 22.3. Increasing the time of exposure of the 85% EtOH soln. to 100 and 200 hrs. raised the yield to 44 and 63.3%, resp. Exposed 3 months in 85% EtOH to sunlight there resulted from 31 to 37% of the *o*-HO deriv., depending upon the type of vessel. There was no change after exposure to electric light for 50 hrs. 2,2'-Azoxytoluene in 85% EtOH, exposed to ultra-violet light, gave an orange-red product, m. 47.5-8.5°, while the product formed in C_6H_6 consisted of red needles, m. 92-3°; the 3,3'-deriv. gave the 2-HO deriv., red, m. 61.5-2.5°; the 4,4'-deriv. gave 10% of the 3-HO deriv., m. 150-1°. 4,4'-Azoxyanisole, 4,4'-azoxyphenetole and 4,4'-dinitroazoxybenzene reacted slightly or not at all. Con-

trary to the work of Janovsky and Reimann (*Ber.* 22, 40(1889)) there is no indication of the existence of an isomer of 4,4'-azoxytoluene. C. J. WEST

Methyl red. H. T. CLARKE AND W. R. KIRNER. *Organic Syntheses II*, 47-51 (1922).—Directions for prepn. of Me red from o -HO₂CC₆H₄NH₂ and PhNMe₂. C. J. WEST

Phenylhydrazine. G. H. COLEMAN. *Organic Syntheses II*, 71-4(1922).—Detailed directions for the prepn. of 80-4% of PhNHNH₂ from PhNH₂. C. J. WEST

Substituted isodiazomethanes. F. D. CHATTAWAY AND A. J. WALKER. *J. Chem. Soc.* 127, 2407-14(1925).— o -O₂NC₆H₄CH:NNHPh (I) and 2 mols. Br in AcOH give ω -bromo- o -nitrobenzaldehyde p -bromophenylhydrazone, amorphous red solid, which easily loses HBr (best by warming in C₆H₆ with concd. aq. NH₃), giving 1- q -bromophenyl-3- o -nitrophenylisodiazomethane, yellow, explodes 144° without melting; this is best prepd. by adding to 5 g. I and 10 g. AcONa in AcOH 6 g. Br in AcOH (yield, 5 g.). I and 3 mols. Br give the ω -bromo-2,4-dibromo deriv., pale yellow, m. 110° (70% yield); it also results from 1 mol. Br and o -O₂NC₆H₄CH:NNHC₆H₄Br₂. A soln. in C₆H₆ shaken with NH₄OH or treated with NH₃ gas, an AcOH soln. shaken with AcONa or an EtOH soln. gently boiled for a few min. gives 1-2,4-dibromophenyl-3- o -nitrophenylisodiazomethane (II), yellow, explodes 145-6° without melting; mol. wt. in CHCl₃, 373. ω -Bromo- o -nitrobenzaldehyde 2,4-dichlorophenylhydrazone (III), pale yellow, m. 122°. NH₄OH gives the 1-2,4-di-Cl deriv. corresponding to II, bright yellow, explodes 140°. The 2,4,6-tri-Cl deriv. corresponding to III exists in 2 polymorphic modifications: light yellow needles, transformed in warm AcOH to pale yellow compact prisms, m. 115-6°. The 2,4,6-tri-Cl deriv. corresponding to II, bright yellow, explodes 163° mol. wt. in CHCl₃, 365. The 3,4,5-tri-Cl deriv. corresponding to II, pale yellow, m. 170° (decompn.); with NH₄OH it gives the 3,4,5-tri-Cl deriv. corresponding to III, yellow, explodes 151°. 1- p -Chlorophenyl-3- o -nitrophenylisodiazomethane, bright yellow, explodes 147°. ω -Chloro- o -nitrobenzaldehyde 2,4-dichlorophenylhydrazone, yellow, m. 132°; the 2,4,6-tri-Cl deriv., yellow, m. 107°. With NH₄OH these give the derivs. described above. All the ω -halogen derivs. yield deep green colors with a trace of oxidizing agent in concd. H₂SO₄. All these derivs. are decompd. by EtOH-KOH or EtOH-NH₃, yielding a halogen-substituted benzene. C. J. WEST

β -Phenylhydroxylamine. OLIVER KAMM. *Organic Syntheses IV*, 57-8(1925).—PhNO₂ is reduced by Zn dust and NH₄Cl, giving 62-7% of PhNH₂. C. J. WEST

4- m -Nitrophenylsemicarbazide and certain derivatives. A. S. WHEELER AND T. T. WALKER. *J. Am. Chem. Soc.* 47, 2792-6(1925); cf. *C. A.* 19, 478.—O₂NC₆H₄NHCONH₂ and 2 mol. equivs. of 42% N₂H₄·H₂O give 36% 4- m -nitrophenylsemicarbazide, pale yellow, m. 138-9°. It reduces Fehling soln. and AgNO₃·NH₄OH in the cold; it dissolves in about 4 parts boiling EtOH; strong alkalis give a red color. HCl salt, sol. in about 10 parts hot EtOH and readily hydrolyzed by aq. solns. of strong alkalis. The following derivs. were prepd.: acetone, yellow, m. 210-1°; chloroacetone, pale yellow, m. 238°; methyl ethyl ketone, pale yellow, m. 205°; acetophenone, m. 211-2°; benzophenone, light yellow, m. 133-6°; camphor, m. 240-2°; cyclohexanone, m. 219-20°. C. J. W.

Phenylcarbamyl derivatives of nitrophenols. O. L. BRADY AND JACK HARRIS. *J. Chem. Soc.* 127, 2175-6(1925).—The O₂NC₆H₄OH (4.8 g.) is gently boiled with 5 g. PhNC in PhMe for 3 hrs. The product crystg. on cooling is washed with cold 2 N NaOH and crystd. from CHCl₃. m -Nitrophenyl phenylcarbamate, m. 129°. C. J. W.

Cupferron. C. S. MARVEL. *Organic Syntheses IV*, 19-21(1925).—Moist PhNH₂ in Et₂O is satd. with NH₃ and then treated with BuONO (the stream of NH₃ being continued during the addn.). There results 85-90% of PhN(NO)ONH₂. C. J. WEST

Sodium p -hydroxybenzenesulfonate. W. G. CHRISTIANSEN AND A. J. NORTON. *Organic Syntheses IV*, 65-8(1923).—PhOH and H₃AsO₄, heated at 155-60°, give 33% of HOC₆H₄AsO₃H₂. C. J. WEST

Arsanilic acid. W. L. LEWIS AND H. C. CHEETHAM. *Organic Syntheses III*, 13-6(1923).—Prepn. from PhNH₂ and H₃AsO₄. C. J. WEST

Relative rates of conversion of phenoxyphenyldichloroarsines and its chloro derivatives into chlorophenoxarsines. ELWYN ROBERTS AND E. E. TURNER. *J. Chem. Soc.* 127, 2004-12(1925); cf. Turner and Sheppard, *C. A.* 19, 1699.—T. and S. showed that PhOC₆H₄AsCl₂ (I) gave 5-chlorophenoxarsine when distd. *in vacuo* and suggested that polarity effects might account for this unusual ring closure. The work has been extended to Cl derivs. of I and it is shown that the polarizing effect of the Cl atom is not the sole detg. influence affecting ring closure. 2-Chloro-2'-nitrodiphenyl ether (II), yellow, m. 48°, b₂ 209°; 55% yield. The 3-Cl deriv. (III), yellow oil, b₂ 204°; 58% yield. The 4-Cl deriv. (IV), yellow, m. 44-5°, b₁ 208°; 75% yield. These are reduced by Fe filings and H₂O. 2-Chloro-2'-aminodiphenyl ether, m. 44-5°, b₂ 185°; 90% yield;

HI salt, m. 171–3°; 3-*Cl* deriv., b_p 195°; 91% yield; *HCl* salt, m. 149–51°; *Bz* deriv., m. 106°. 4-*Cl* deriv., yellow oil, b_p 202°; *HI* salt, m. 190–1°; *Bz* deriv., m. 108–9°. These were converted into arsenic acids by neutralizing the diazo soln. with NaHCO_3 , treating with a little CuSO_4 soln., and then adding an arsenite soln. contg. 0.75 mol. As_2O_3 , 2 mols. NaOH , 0.7 mol. Na_2CO_3 , 7 mols. H_2O and a little CuSO_4 . 2-*o*-Chlorophenoxyphenylarsinic acid, m. 195–5.5°; 18% yield; 2-*m*-*Cl* deriv., m. 177–9°; 18% yield; 2-*p*-*Cl* deriv., m. 187–8°; 24% yield. 2-*o*-Chlorophenoxyphenyldichloroarsine, pale yellow oil, b_p 217°; 2-*m*-*Cl* deriv., pale yellow, b_p 220°; 2-*p*-*Cl* deriv., pale yellow, m. 67–8°, b_p 220°. 8-Chlorophenoxyarsinic acid, m. 250–2°; the 7-*Cl* acid, m. 240–2°. Reduction gave 5,8-dichlorophenoxyarsine, m. 125°, and the 5,7-deriv., m. 144–5°; 5,9-deriv., pale yellow, m. 99°. The 5,8-deriv. was synthesized as follows: 5-chloro-2-nitrodiphenyl ether, m. 85°, was reduced to the 2-amino deriv., indefinite m. p., this transformed into 4-chloro-2-phenoxyphenylarsinic acid, m. 82°, then into 4-chloro-2-phenoxyphenyldichloroarsine, m. 91–2° and finally into the 5,8-deriv. The rate of conversion was detd. by heating about 1 g. in an atm. of CO_2 , the HCl liberated being absorbed by 0.1 *N* KOH . The % decompn. is given for 1–6 hrs. The initial and final values reported are: I, 23.7, 56.6; II, 1.86, 24.3; III, 8.90, 37.8; IV, 1.09, 27.0. C. J. WEST

Sulfur content of arspenamine and its relation to the mode of synthesis and the toxicity. V. W. G. CHRISTIANSEN, A. J. NORTON AND J. B. SHOHAN. *J. Am. Chem. Soc.* 47, 2712–24(1925); cf. C. A. 17, 2475.— $3,4\text{-O}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ is reduced by NaHSO_3 in 3 ways: In boiling H_2O , the C-As bond is severed and $o\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$ is obtained. At room temp. in H_2O the Na salt is reduced mainly to 3-nitro-4-hydroxyphenylarsenious oxide, yellow, reduces I and is reduced by H_3PO_2 to a pale yellow insol. substance. The dry powder causes sneezing. The mother liquor shows the presence of a sulfamic acid. The tri-Na salt under these conditions is reduced to salts of sulfamic acids which are very sol. in H_2O and which can be isolated by a tedious process. There were isolated and analyzed *di*-Ba 2-hydroxy-5-arsonobenzenesulfamate, yellow; with H_2SO_4 these results impure $3,4\text{-H}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$; *tri*-Ba 2-hydroxy-3-sulfo-5-arsonobenzenesulfamate, needles, yielding on hydrolysis with concd. H_2SO_4 3-amino-4-hydroxy-5-sulfophenylarsonic acid, m. 243–4°; *tetra*-Ba 2,2'-dihydroxy-5,5'-diarsonosulfonamide-*N,N'*-disulfonate, yellow, which yields $3,4\text{-H}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ on hydrolysis. $3,1\text{-O}_2\text{N}(\text{MeO})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ is also reduced by NaHSO_3 to very sol. compds. of the sulfamic acid series. When mixts. of the sulfamic acids which are formed by the action of NaHSO_3 on $3,4\text{-O}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ and $3,4\text{-H}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ are reduced by $\text{Na}_2\text{S}_2\text{O}_4$, the rate of formation of insol. reduction products is much less than when the NH_2 acid is reduced to arspenamine base in the usual way and the products sep. from the soln. in a different condition from that of arspenamine base. The behavior of these bases in MeOH-HCl is also quite different from that of arspenamine base. These products are more toxic and contain more S than arspenamine prepd. from the NH_2 acid. When $3,4\text{-O}_2\text{N}(\text{OH})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ is reduced with $\text{Na}_2\text{S}_2\text{O}_4$ to $3\text{-H}_2\text{N}(\text{HO})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$, 2 by-products are formed which may be isolated and sep'd. by means of their Ba salts. Reduction of a mixt. of I of these by-products and the pure NH_2 acid yields a product which is much more toxic and contains more S than arspenamine prepd. from the NH_2 acid. BaBr_2 is recommended for the prepn. of Ba salts when EtOH solvents are used. Its prepn. is described. C. J. WEST

Organic compounds of arsenic. III. Reaction between arsenic trichloride and α -naphthyl compounds of mercury. KAORU MATSUMIYA. *Mem. Coll. Sci. Kyoto Imp. Univ.* 8, 391–6(1925); cf. C. A. 19, 3086; (in English).— AsCl_3 and $\alpha\text{-C}_{10}\text{H}_7\text{HgCl}$ at 160° give $\alpha\text{-C}_{10}\text{H}_7\text{AsCl}_2$ and HgCl_2 . Heating ($\alpha\text{-C}_{10}\text{H}_7$) $_2\text{Hg}$, AsCl_3 and C_6H_6 in a sealed tube at 145° for several hrs. gives HgCl_2 , $\alpha\text{-C}_{10}\text{H}_7\text{HgCl}$, ($\alpha\text{-C}_{10}\text{H}_7$) $_2\text{AsCl}$ and ($\alpha\text{-C}_{10}\text{H}_7$) $_3\text{As}$. SbCl_3 and $\alpha\text{-C}_{10}\text{H}_7\text{HgCl}$ remained unchanged after heating in $\text{C}_6\text{H}_6\text{Me}_2$ at 145° for 8 hrs. On heating ($\alpha\text{-C}_{10}\text{H}_7$) $_2\text{Hg}$ and SbCl_3 at 145° for 8 hrs, there result $\alpha\text{-C}_{10}\text{H}_7\text{HgCl}$, SbCl_3 and an Sb compd. of unknown compn. C. J. WEST

o-Chloromercuriphenol. F. C. WHITMORE AND E. R. HANSON. *Organic Syntheses* IV, 13–4(1925).— PhOH and $\text{Hg}(\text{OAc})_2$ give $\text{HOC}_6\text{H}_4\text{HgOAc}$, which is treated in soln. with NaCl , giving 44% of *o*- $\text{HOC}_6\text{H}_4\text{HgCl}$. C. J. WEST

Mercury di-*p*-tolyl. F. C. WHITMORE, N. THURMAN AND FRANCES H. HAMILTON. *Organic Syntheses* III, 65–6(1923).— $\text{MeC}_6\text{H}_4\text{HgCl}$ and NaI give 78–85% of (MeC_6H_4) $_2\text{Hg}$. C. J. WEST

p-Tolylmercuric chloride. F. C. WHITMORE, F. H. HAMILTON AND N. THURMAN. *Organic Syntheses* III, 99–100(1923).— HgCl_2 and *p*- $\text{MeC}_6\text{H}_4\text{SO}_3\text{Na}$ give 51–7% $\text{MeC}_6\text{H}_4\text{HgCl}$. C. J. WEST

A new method for the preparation of symmetric organo-mercury compounds. FR. HEIN AND K. WAGLER. *Ber.* 58B, 1499–509(1925).—In attempts to prep. organo-

Cu compds. from Hg dialkyls (e. g., HgPh_2) by treatment in $\text{C}_6\text{H}_5\text{N}$ with metallic Cu, an intense yellow-green color appeared even in the cold in 15–30 min. and the Cu became visibly amalgamated. The soln. was found, however, to contain but a fraction of a mg. of dissolved Cu per cc. and the phenomenon was traced to the presence of PhHgCl as an impurity in the HgPh_2 ; PhHgBr with Cu in $\text{C}_6\text{H}_5\text{N}$ gives the same yellow-green color and pptn. of Hg in a few min. and the resulting soln. yields halogen-free HgPh_2 . The reaction can therefore be used for the purification of the HgR_2 which, after 1 or more such treatments, no longer react at all with Cu in $\text{C}_6\text{H}_5\text{N}$, and also as a practical method for the prepn. of HgR_2 from RHgX (in the case of MeHgI and EtHgCl , the products, HgMe_2 and HgEt_2 , being liquid and volatile, cannot be well sep'd. from the $\text{C}_6\text{H}_5\text{N}$, but detns. of the amt. of dissolved Cu or pptd. Hg indicate that the reaction proceeds practically quant.). This new method of synthesis proceeds smoothly even in a no. of cases where all the earlier methods are largely unsuccessful. After the reaction is over the $\text{C}_6\text{H}_5\text{N}$ is removed *in vacuo* below 40° and the Cu compds. are dissolved away with cold NH_4OH . The following compds. were prepd. by the new method (yield in parentheses): $\text{Hg}(\text{CH}_2\text{Ph})_2$ (I), m. 111° (75%); $(1-\text{C}_{10}\text{H}_7)_2\text{Hg}$, m. $243-5^\circ$; (*p*- MeNC_6H_4) $_2\text{Hg}$, m. $167-8^\circ$ (81%); *bis*-[*o*-nitrophenyl]mercury, faintly yellow, m. $206-7^\circ$ (92%); *bis*-[*p*-chlorophenyl]mercury, m. $242-3^\circ$ (81%); *bis*-[*p*-bromophenyl]mercury, m. $244-5^\circ$ (92%). I in boiling alc. showed a mol. wt. of 466 (calcd. 382.8) and after addn. of 1 equiv. HgCl_2 395 (calcd. for PhCH_2HgCl , 327.2); preformed PhCH_2HgCl showed 346–8. C. A. R.

Benzenesulfonyl chloride. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 21–3 (1921).—Prepn. of PhSO_2Cl from PhSO_3Na and PCl_5 or POCl_3 . C. J. WEST
***p*-Acetaminobenzenesulfonic acid.** S. SMILES AND C. M. BERE. *Organic Syntheses V*, 1–2 (1925).—Crude *p*- $\text{AcNHC}_6\text{H}_4\text{SO}_2\text{Cl}$, shaken with Na_2SO_3 , gives 43–7% of $\text{AcNHC}_6\text{H}_4\text{SO}_2\text{H}$, m. 155° (decompn.). C. J. WEST

***p*-Acetaminobenzenesulfonyl chloride.** S. SMILES AND JESSIE STEWART. *Organic Syntheses V*, 3–4 (1925).— PhNHAc added to HOSO_2Cl at 15° and then heated 2 hrs. at 60° gives 75% of *p*- $\text{AcNHC}_6\text{H}_4\text{SO}_2\text{Cl}$. C. J. WEST

Sodium *p*-toluenesulfinate. F. C. WHITMORE AND F. H. HAMILTON. *Organic Syntheses II*, 89–91 (1922).—Reduction of $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ by Zn and transformation of the Zn salt into the Na salt by Na_2CO_3 gives 64% of $\text{MeC}_6\text{H}_4\text{SO}_2\text{Na}$. C. J. WEST

Alcoholysis of trinitroanisole and trinitrophenetole. O. L. BRADY AND H. V. HORTON. *J. Chem. Soc.* 127, 2230–3 (1925).—The f. p. curve of mixts. of 2,4,6-(O_2N) $_3$ - $\text{C}_6\text{H}_2\text{OMe}$ (I) and 2,4,6-(O_2N) $_3$ - $\text{C}_6\text{H}_2\text{OEt}$ (II) was detd. from time-cooling curves: % of I and f. p.: 0, 77.6° ; 10, 72.6° ; 20, 67.9° ; 30, 62.9° ; 40, 56.4° ; 50, 48.1° ; 55, 43.0° ; 56, 42.0° ; 57.5, 40.1° ; 60, 41.0° ; 62.5, 40.3° ; 65, 39.4° ; 67.5, 39.2° ; 70, 41.7° ; 80, 53.0° ; 90, 59.3° ; 100, 67.0° . In mixts. of EtOH and I in the mol. proportions of 11 to 1 and 16 to 1 conversion occurred to the extent of 16 and 22% resp.; with larger amts. of EtOH, the results were irregular but even with 68 mols. not more than 35% of I was converted into II. C. J. WEST

Thiophenol. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 71–4 (1921).—Reduction of PhSO_2Cl with Zn and H_2SO_4 gives 91% of PhSH . C. J. WEST

Reaction between organic peroxides and organomagnesium halides. HENRY GILMAN AND C. E. ADAMS. *J. Am. Chem. Soc.* 47, 2816–21 (1925).—The following reaction takes place: $\text{ROOR} + \text{R}'\text{MgX} = \text{ROR}' + \text{ROMgX}$. Reaction does not take place with every peroxide and the rate of reaction varies appreciably with different peroxides. Bz_2O_2 (I) (0.416 mol.) and 0.41 mol. PhMgBr gave 28% BzOPh and BzOH ; 0.82 mol. PhMgBr gave 3.6% BzOPh and 23% PhCOH . I (0.2 mol.) and 0.25 mol. EtMgBr gave 10% BzOEt . I (0.083 mol.) and 0.43 mol. BuMgBr gave 72% BuPhCOH . I (0.04 mol.) and 0.2 mol. PhCH_2MgCl gave 73% $(\text{PhCH}_2)_2\text{PhCOH}$. Triacetone peroxide (0.09 mol.) and 0.8 mol. PhMgBr gave 25% Me_3PhCOH and 66% PhOH (in PhOMe soln.; no reaction in Et_2O). Et_2O_2 (0.5 mol.) and 0.63 mol. PhMgBr gave 34% PhOEt and 30% Ph_2 ; this suggests a correspondence in structure between this peroxide and azo compounds. $(\text{Ph}_3\text{C})_2\text{O}_2$ and succinic peroxide do not react with PhMgBr . C. J. WEST

***p*-Bromophenol.** ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 39–43 (1921).—Prepn. of *p*- $\text{BrC}_6\text{H}_4\text{OH}$ from PhOH and Br_2 . C. J. WEST

***o*-Iodophenol.** F. C. WHITMORE AND E. R. HANSON. *Organic Syntheses IV*, 37–8 (1925).—A suspension of *o*- $\text{HOC}_6\text{H}_4\text{HgCl}$ and I_2 in CHCl_3 give 63% of *o*- $\text{IC}_6\text{H}_4\text{OH}$. C. J. WEST

***m*-Nitrophenol.** ROGER ADAMS AND W. C. WILSON. *Organic Syntheses III*, 87–90 (1923).—The diazo soln. from $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ is decompd. by heating with dil. H_2SO_4 , giving 80–5% of $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$. C. J. WEST

p-Cresol. W. W. HARTMAN. *Organic Syntheses* III, 37-9(1923).—*p*-MeC₆H₄-H₂SO₃Na and KOH (fusion) give 60-70% of MeC₆H₄OH. C. J. WEST

Pyrocatechol. H. D. DAKIN. *Organic Syntheses* III, 27-32(1923).—*o*-C₆H₄-(OH)₂ is obtained in 69-74% yields from NaOC₆H₄CHO and H₂O₂ or in 77-80% from MeOC₆H₄OH and HBr. C. J. WEST

Hydroxyhydroquinol triacetate. E. B. VLIET. *Organic Syntheses* IV, 35-6(1925).—*O*. C₆H₄ O, heated with Ac₂O and H₂SO₄ at 40-50°, gives 85-7% of 1,2,4-C₆H₃(OAc)₃. C. J. WEST

Quinone. E. B. VLIET. *Organic Syntheses* II, 85-8(1922).—*O*:C₆H₄:O results in 85-90% yields by oxidation of *p*-C₆H₄(OH)₂ by Na₂Cr₂O₇ and H₂SO₄. C. J. W.

The reduction of nitrosophenols with alkali sulfides. A. PORAT-KOSHITZ. *Chem.-Ztg.* 49, 595-6(1925).—NH₄OH (d. 0.94), was satd. with *p*-ONC₆H₄OH (I) at 45-50°, and H₂S led in with cooling until satn. was reached. *p*-Aminophenol (II) began to sep. at once and was filtered off at the end. Yield, 80% of crystals, m. 182-3°, and nearly free from S. At 70° the yield dropped to 70%, while at 20° the reaction was too slow and the product impure. The same mother-liquor could be used 3-4 times but the yield gradually dropped and the product became less pure. With Na₂S, 11 parts of Na₂S in 20 parts of H₂O were held at 50° and stirred under a reflux with 8 parts of I and the alkali neutralized with 11 parts of (NH₄)₂SO₄ in 16.5 parts of H₂O, thus pptg. II due to hydrolysis of the NH₄ salt. Neutralization with acid caused losses due to tar formation. As before, lower temps. caused slow reaction and impure products, and higher temps. or boiling reduced the yield. The NH₃ liberated was collected in H₂SO₄ and used again. Also NH₃ was recovered from the mother-liquor. Yield of II, 90-3%, m. 178-80°. M. A. YOUTZ

Nitrosation of phenols. II. Nitrosation of 3-bromo-, 2-bromo-, 3-iodo- and 2-iodophenol. Evidence for the nitroso formula of 4-nitrosophenol. HERBERT HENRY HODGSON and FRANCIS HARRY MOORE. *J. Chem. Soc.* 127, 2260-4(1925); cf. C. A. 18, 235.—3-Bromo-4-nitrosophenol (I), yellow, m. 139° (decompn.); crystd. from C₆H₆, dil. HCl or dil. EtOH, it yields 3-bromo-*p*-benzoquinone 4-oxime (II), orange, m. 188° (decompn.), mol. wt. in freezing PhOH, 189; all solvents tried except cold Et₂O effect the conversion. I dissolves in 10% aq. NaOH to a red soln. which froths after a few sec.; if acidified immediately, the soln. deposits a pale yellow substance, m. 189-90°; if allowed to stand, a dark colored substance of indefinite m. p. is formed. The orange form of II in NaOH, on acidification, deposits the colorless form; crystn. from dil. HCl gives the colored form. Oxidation of I gives 3,4-Br(O.N)₂C₆H₃OH. 2-Bromo-4-nitrosophenol, red from dil. HCl, light brown from C₆H₆, m. 150°; it is not transformed into a quinone oxime by hot dil. mineral acids. Liebermann's NO reaction gives a deep green color, changing to wine-red on diln. 3-Iodo-*p*-benzoquinone 4-oxime, deep yellow, m. 185-95°, mol. wt. in freezing PhOH, 254; this is assumed to be the *syn*-form. Soln. in 10% NaOH and acidification give the *anti*-form, pale straw-colored, decomp. about 185°, mol. wt. in PhOH, 160. The Liebermann reaction gives a yellowish brown color. Oxidation gives 3-iodo-4-nitrophenol, m. 123°. The main product of the action of Am-NO₂ and glacial AcOH on 2-IC₆H₄OH is the 6-NO₂ deriv. In H₂O with NaNO₂ there results 2-iodo-4-nitrosophenol, yellow, decomp. 152°, mol. wt. in freezing PhOH, 255. No conversion into a quinone oxime could be effected. The color produced by the Liebermann reaction was deep green, changing to crimson on diln. and to blue when made alk. C. J. WEST

Benzyl benzoate. O. KAMM and W. F. KAMM. *Organic Syntheses* II, 5-8(1922).—BzOCH₂Ph is obtained in 90-3% yields from BzH and PhCH₂ONa. C. J. WEST

Substitution in derivatives of quinol ethers. LEON RUBENSTEIN. *J. Chem. Soc.* 127, 1998-2001(1925).—Nitration of 2,5-HO(MeO)₂C₆H₃CHO (I) in glacial AcOH at 10-20° gives 88% of the 3-nitro deriv. (II), bright yellow, m. 132°; it does not yield an indigotin deriv.; FeCl₃ gives a red color; *p*-nitrophenylhydrazone, scarlet, decomp. 250°. With MeI and Ag₂O I gives quant. 3-nitro-2,5-dimethoxybenzaldehyde (III), pale yellow, m. 113°. Boiling 10% NaOH gives I. Bromination of I in glacial AcOH contg. AcONa gives 80% of the 3-Br deriv., light brown, m. 107°; *p*-nitrophenylhydrazone, scarlet, decomp. above 250°. 3-Bromo-2,5-dimethoxybenzaldehyde, m. 63°. Nitration of 2,5-(MeO)₂C₆H₃CHO at room temp. gives 20% III and 80% of the 6-nitro deriv., pale yellow, m. 159°; *p*-nitrophenylhydrazone, scarlet, m. 245-50° (decompn.). Aq. KOH gives 4,4',7,7'-tetramethoxyindigotin, deep purple, sublimes at 350°. Bromination of 2,5-(MeO)₂C₆H₃CHO gives only the 6-Br deriv., pale gray, m. 125-8°; *p*-nitrophenylhydrazone, scarlet, m. 204-6°. 3-Amino-2,5-dimethoxybenzoic acid, turns black 170°, decomp. 210-5°. 4-Bromo-2,5-dimethoxyacetanilide, pale pink, m. 122° (80% yield); hydrolysis with 20% EtOH-HCl gives 4-bromo-2,5-dimethoxyaniline, pale pink,

m. 106°. **4-Nitro-2,5-dimethoxyacetanilide**, yellow, m. 165°; 90% yield. Hydrolysis gives **4-nitro-2,5-dimethoxyaniline-HCl**, yellow, m. 160° (decompn.). C. J. WEST

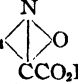

Substitution in vicinal trisubstituted benzene derivatives. III. LEON RUBENSTEIN. *J. Chem. Soc.* **127**, 2268-9 (1925); cf. *C. A.* **18**, 386.—The nitration product of $3,2\text{-MeO}(\text{EtO})\text{C}_6\text{H}_3\text{CHO}$ is sepd. by condensation with $p\text{-H}_2\text{NC}_6\text{H}_4\text{Me}$ and careful fractional crystn.; it contains 60% of the 5- NO_2 and 40% of the 6- NO_2 deriv. **5-Nitro-3-methoxy-2-ethoxybenzylidene-*p*-toluidine**, pale yellow, m. 148°. The **6-nitro deriv.**, golden prisms, m. 88°; hydrolysis gives **6-nitro-3-methoxy-2-ethoxybenzaldehyde**, m. 57° (*p*-nitrophenylhydrazone, brown, m. 188-9°), oxidized by KMnO_4 to the corresponding acid, m. 119-20°. **5-Nitro-2,3-diethoxybenzaldehyde**, m. 71°; the *p*-toluidine deriv., cream needles, m. 105-6°; the **6-nitro deriv.**, m. 75-6°, turns green on exposure to the air, gives a *p*-nitrophenylhydrazone, bright yellow, m. 268-70°, and a *p*-toluidine deriv., m. 100°. The sepn. of these 2 compds. was incomplete. There is evidence that in both nitrations some 4- NO_2 deriv. is formed. C. J. WEST

Isomerism of the oximes. XXIII. Acyl derivatives. O. L. BRADY AND G. P. McHUGH. *J. Chem. Soc.* **127**, 2414-27 (1925); cf. *C. A.* **19**, 2650.—The present status of this study is shown by a table, which gives the products formed by the action of various reagents on various oximes. The following **Bz derivs.** were prepd. from the α -oxime in 2 *N* NaOH and BzCl ; the orientation of the product was detd. by hydrolysis with warm 2 *N* NaOH: *o*-Nitro- α -benzaldoxime, pale greenish white, m. 112°; *p*-deriv., pale greenish white, m. 196°; **3,4-methylenedioxy- α -benzaldoxime**, m. 168°; *o*-methoxy- α -benzaldoxime, m. 96°; *p*-dimethylamino- α -benzaldoxime, greenish white, m. 138°. In all cases studied, BzCl and β -oximes gave the *Bz* deriv. of the α -oxime, whether 2 *N* NaOH or $\text{C}_6\text{H}_5\text{N}$ was used as the solvent. Ketene and **3,4-methylenedioxy- α -benzaldoxime** gave the *Ac* deriv., m. 105°, identical with the product obtained from Ac_2O ; similar derivs. were obtained from *m*- and *p*-nitro- α -benzaldoxime. β -Aldoximes and ketene give nitriles. Diphenyl ketoxime gives the *Ac* deriv., m. 74°. The following *Ac* derivs. of β -aldoximes were prepd. with Ac_2O at -20° in a room free from acid fumes and illuminated by deep orange light only: *o*-nitro- β -benzaldoxime, m. 73°; *m*-deriv., m. 96-8°; *p*-deriv., m. 96°; **3,4-methylenedioxy- β -benzaldoxime**, m. 86°. $\text{N}_2\text{CHCO}_2\text{Et}$ and α -aldoximes gave unchanged α -aldoximes, while the β -derivs. gave a mixt. of the α - and β -forms, owing to isomeric change of the former into the latter. **Carbanilino-3,4-methylenedioxy- α -benzaldoxime**, m. 101°; the corresponding β -deriv., greenish white, m. 84°; attempts to cryst. the compd. led to isomeric change. The crude product is probably a mixt. of these 2 products. *p*-Nitro- α -benzaldoxime likewise gives a mixt. of the α - and β -derivs. The *o*-deriv. gives only the α -form. **Carbanilino-*o*-methoxy- α -benzaldoxime**, m. 107° (decompn.). *m*-Nitro- and *p*-methoxy- α -benzaldoxime and phenylcarbamyl chloride give the carbanilino- α -derivs. The Na salt of $o\text{-MeOC}_6\text{H}_4\text{CH:NOH}$ gives diphenylcarbamyl- α -methoxy- β -benzaldoxime, m. 124°. **Carbethoxy- α -cinnamaldoxime**, pale yellow, m. 64°. The β -oxime gives the nitrile. **α -Naphthylcarbamyl- α -cinnamaldoxime**, pale yellow, m. 152° (decompn.); the corresponding β -cinnamaldoxime, deep yellow, m. 125° (decompn.), ppts. from Me_2CO on addn. of H_2O in a colorless form, m. 125° (decompn.); a mixt. of the 2 forms also m. 125°. **XXIV. 4-Methoxy-3-methyl-, 3-nitro-4-methyl- and some *o*-substituted benzaloximes.** O. L. BRADY, ANTOINETTE N. COSSON AND ARTHUR J. ROPER. *Ibid* 2427-32.—***o*-Chloro- α -benzaldoxime-HCl**, m. 108° (decompn.). In the prepn. of the *o*-Br deriv., there is first formed *o*-bromobenzylidene diacetate, m. 84-6°, which is hydrolyzed to the aldehyde and then oxidated. **Acetyl-*o*-bromo- α -benzaldoxime**, m. 66°. Satd. with HCl , the α -deriv. gives *o*-bromo- β -benzaldoxime, m. 126°. The α -oxime *HCl* salt, m. 115° (decompn.). No β -deriv. could be obtained from the *o*-I or *o*-EtO derivs. The *o*-I deriv. with 30% NaOH gives *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$; the other *o*-derivs. showed little or no reaction. **Acetyl-4-methoxy-3-methyl- α -benzaldoxime**, m. 70°. The α -oxime, boiled 90 min. with excess Ac_2O , gives **4-methoxy-3-methylbenzonitrile**, m. 51-2°, hydrolyzed to the corresponding acid, m. 192°. **4-Methoxy-3-methyl- β -benzaldoxime**, m. 121°. **3-Nitro-4-methyl- α -benzaldoxime**, pale yellow, m. 118-20°; *Ac* deriv., m. 104°. The β -oxime, m. 135°; *HCl* salt, m. 140°; with Ac_2O , it gives the nitrile. C. J. WEST

***p*-Dimethylaminobenzaldehyde.** ROGER ADAMS AND G. H. COLEMAN. *Organic Syntheses II*, 17-21 (1922).—Prepn. of $\text{Me}_2\text{NC}_6\text{H}_4\text{CHO}$ from $\text{Me}_2\text{NC}_6\text{H}_4\text{NO}$, HCHO and PhNMe_2 and its purification. C. J. WEST

Structural formulas of anthranil and of anthroxanic acid. HERMANN LEUCHS. *Ber* **58B**, 1452-4 (1925).—Anthroxanic acid (I) forms with alkaloids salts sepg. from ales and especially from H_2O in well-formed crystals, which are always homogeneous in appearance, even when their amt. is considerably more than 0.5 of the total possible quantity, and on recrystn. from H_2O until they are diminished in amt. to 0.5 or less,

neither does their form change nor does the soln. of the NH_4 salt obtained from them show the slightest optical activity. L. concludes that I (and hence anthranil also) contains

no asym. C atom and has the structure $\text{HO}_2\text{CC}:\text{C}_6\text{H}_4:\text{N}:\text{O}$ rather than C_6H_4  CO_2H

Bromine salt, $\text{C}_{11}\text{H}_9\text{O}_2\text{N}_2$, H_2O , sinters 200° , m. $210\text{--}2^\circ$ (gas evolution). *Quinine salt*, sinters 190° , m. $198\text{--}202^\circ$ (foaming). *Strychnine salt*, prisms with $1\text{H}_2\text{O}$, sinters 200° , m. about $210\text{--}12^\circ$ (gas evolution). C. A. R.

Action of aldehydes on the Grignard reagent. III. JOSEPH MARSHALL. *J. Chem. Soc.* **127**, 2184-8(1925); cf. C. A. **9**, 2224. — $\text{PhCH}:\text{CHCHO}$ (2 mols., 264 g.) and 1 mol. MeMgI gave about 10 g. recovered aldehyde, 4 g. $\text{PhCH}:\text{CHCO}_2\text{H}$, a fraction b_{16} $220\text{--}60^\circ$ (20 g.), which was not examd., and a fraction (165 g.) b_{16} $150\text{--}80^\circ$; from the latter were isolated 100 g. $\text{PhCH}:\text{CHAc}$ (as the phenylhydrazone, m. 158°) and $\text{PhCH}:\text{CHCH}_2\text{OH}$, isolated as the *p*-nitrobenzoate, m. 76° . There was no indication of $\text{PhCH}:\text{CHCHMeOH}$. Similarly from EtMgI there were obtained $\text{PhCH}:\text{CHCOEt}$, $\text{PhCH}:\text{CHCH}_2\text{OH}$, and a bright yellow product, m. 158° , which has not been identified. $(\text{HCHO})_2$ (2 mols.) and 1 mol. PhMgBr gave a considerable quantity of BzH , although the chief product of the reaction was PhCH_2Br ; Ph_2 was also formed. C. J. W.

***p*-Bromoacetophenone.** ROGER ADAMS AND C. R. NOLLER. *Organic Syntheses V*, 17-9(1925). — PhBr , Ac_2O and AlCl_3 give 69-79% of *p*- $\text{BrC}_6\text{H}_4\text{Ac}$. C. J. WEST

Benzalacetone. N. L. DRAKE AND P. ALLEN, JR. *Organic Syntheses III*, 17-9(1923). — BzH and Me_2CO give 65-78% $\text{PhCH}:\text{CHAc}$. C. J. WEST

Benzalacetophenone. I. P. KOHLER AND H. M. CHADWELL. *Organic Syntheses II*, 1-3(1922). — Prepn. of $\text{PhCH}:\text{CHBz}$ from BzH , PhAc and NaOH ; 85% yields. C. J. WEST

Photodimers of some γ -ketopentadiene derivatives. HANS STORBE AND EDUARD FÄRBER. *Ber.* **58B**, 1548-53(1925). — The yellow dibenzalacetone (I) tends to resinify on heating (Herzog and Kreidl, C. A. **17**, 1339) and also on exposure to sunlight in alc. (Ciamician and Silber, C. A. **3**, 2294) but in the presence of UO_2 salts in sunlight it very easily and rapidly gives up to 90% of the colorless bisdibenzalacetone (II), $\text{PhCH}:\text{CHCOCH}:\text{CHPh}$ (Praetorius and Korn, C. A. **5**, 484). S. and F. have

now found that II is likewise obtained (although in much smaller yield on account of tarry by-products) from the orange-yellow compd. 2I. SnCl_4 , C_6H_6 in C_6H_6 suspension exposed to sunlight. The formation of II is so accelerated by the purely catalytic action of the UO_2 or Sn salts or by their increased absorption of the longer wave lengths that the other, slower (resin-forming) reaction is more or less repressed. The absorption curves show that II as compared with I absorbs on an average 200 units further towards the shorter ultra-violet wave lengths and that the deep band of I reappears in broadened and flattened form in II; in 0.0001 to 0.01 *N* CHCl_3 solns., II is more transparent than I. II can very easily be depolymerized: by heating slightly above its m. p. (248°), by concd. H_2SO_4 at room temp., by $\text{Cl}_3\text{CCO}_2\text{H}$, liquefied with a little H_2O , at 25° , and by illumination with a quartz Hg lamp; the equil. in the photo-reaction $\text{I} \rightleftharpoons \text{II}$ therefore depends on the wave length of the light. On the other hand, while di-*p*-anisalacetone (III) likewise resinifies on heating or exposure to light in alc., its UO_2Cl_2 compd. and violet-red SnCl_4 compd., 2III. SnCl_4 , m. 173° , are rather stable towards light, merely undergoing a slight resinification. This photochem. difference between I and III is not due to marked differences in light absorption (III absorbs somewhat more strongly than, but otherwise very much like, I) but to the greater sluggishness of III in certain addn. reactions ($\text{AcCH}_2\text{CO}_2\text{Et}$, Br, etc.). The colorless, satd., "evidently polymeric" compd., m. $240\text{--}1^\circ$, obtained by Straus by exposing the yellow di- γ -ketopentadienedicarboxylate, m. $169\text{--}9.5^\circ$, to sunlight (*Ber.* **37**, 3294(1904)), is bimol. in boiling $(\text{CH}_2\text{Br})_2$ (found mol. wt. 401-20), is only slowly oxidized by KMnO_4 in AcOH and does not add Br but evolves HBr with it; it must therefore have the structure $\text{MeO}_2\text{CCH}:\text{CH}:\text{CO}:\text{CH}:\text{CHCO}_2\text{Me}$. While the monomer in dil. CHCl_3 solu

shows continuous absorption but in 0.1 *N* soln. has a very characteristic flat band with a max. at $1/\lambda$ 2500, the absorption of the dimer is so little greater than that of CHCl_3 that it cannot be detd. even in the most concd. soln. which can be prepd. The yellow di-*Et* ester, m. $49.5\text{--}50^\circ$, is not so stable towards light as might be concluded from S.'s paper. It melts in sunlight to a green-yellow oil and gradually changes, even in pe

troleum ether, into a yellow-brown resin of peculiar odor and strong acid reaction which in H_2O reduces moist Ag_2O and with $PhNHNH_2 \cdot HCl$ gives a yellow ppt. turning brown 220° and black 280° . In spite of their different behavior towards light, the yellow di-Me and di-Et esters show almost identical absorptions. C. A. R.

Oxidation with ozone. III. Preparation of methylvanillin, piperonal, and anisaldehyde. E. BRINER, H. v. TSCHARNER AND H. PAILLARD. *Helvetica Chim. Acta* 8, 406-12(1925); cf. C. A. 18, 1824.—The yield of methylvanillin (I) from methyl-isoeugenol (II) is much better than that of vanillin (III) from isoeugenol (IV), similar to the observation of Fichter that in electrolytic oxidation of phenols, protection of the OH group by methylation improves the yield. From 3 g. of IV in 50 cc. of CCl_4 at -15° , a concn. of 7% O_3 in O_2 , and a rate of 6 l./min., the yield of III was 0.52-0.63 g. in 90 min. but the yield of I from II was 0.94-1.35 g. Isosafrole (V) is oxidized to piperonal (VI) at 20° with a yield of 46% in 30-35 min., with 58% utilization of the O_3 (for the principal reaction). The yields are diminished by shorter or longer treatment, and are not much different at -15° . A 9.8% concn. of O_3 at -15° gives a poorer utilization of O_3 than a 3.2% concn. at 20° , while the yield of VI reaches the same max. value. Piperonylic acid is formed also and largely accounts for the low yields. Anethole (VII) gives a 49-50% max. yield of anisaldehyde (VIII) and 54-7% utilization of O_3 both at 20° and -15° using a 7% concn. of O_3 . A concn. of 9.8% of O_3 at -15° gives a 56% max. yield of VIII with a 57% utilization of O_3 while a 3.1% concn. at 20° gives 43.4% and 40.6% resp. *p*-Cresol Me ether is not oxidized by O_3 under any conditions tried. M. A. YOUTZ

The electrolytic reduction of benzoic acid in boiling solution. V. DECAÏS AND J. DUFOUR. *Bull. soc. chim.* 37, 1167-74(1925).—An app. is described for carrying out the reduction of BzOH in boiling aq. H_2SO_4 (no alc.). The following conditions were found to give the best yields: (1) $R = 1/1.6$ (where $R = \frac{\text{cathode surface in cm.}^2}{\text{vol. of cathode soln. in cc.}}$); (2) concn. of $H_2SO_4 = 60\%$; (3) cathode density = 12-13 amp. per dm.² BzII is not detected but the production of isohydrobenzoin is evidence that the aldehyde is an intermediate product in the reduction. Yield: $PhCH_2OH$, 75-80%; benzyl ether 20-16%; isohydrobenzoin 2-1%, tar 3%. REYNOLD C. FUSON

Benzoic anhydride. H. T. CLARKE AND E. J. RAHRS. *Organic Syntheses* III, 21-4(1923).—BzOH and Ac_2O give 72-4% of Bz₂O. C. J. WEST

2-Chloro-3,5-dinitrobenzamide. E. DEB. BARNETT. *Ber.* 58B, 1610-1(1925).—2-Chloro-3,5-dinitrobenzoyl chloride, from the acid with boiling $SOCl_2$, gives with NH_4Cl in CCl_4 the amide, m. 180° , with $PhNH_2$ the anilide, S-yellow, m. 177° , and with 1- and 2- $C_6H_4(CO)_2C_6H_4NH_2$ in $(CHCl_3)_2$ 1- and 2-[2'-chloro-3',5'-dinitrobenzoylamino]-anthraquinone, golden yellow, m. 278° , and yellow, m. 302° , resp. C. A. R.

Imino-aryl ethers. III. The molecular rearrangement of *N*-phenylbenziminophenyl ether. A. W. CHAPMAN. *J. Chem. Soc.* 127, 1992-8(1925); cf. C. A. 17, 2561.— $PhOCPh:NPh$ was heated in a thermostat maintained at temps. between 220° and 300° and the product submitted to thermal analysis; the f. p. curve of the mixt. of $PhOCPh:NPh$ and $O \cdot CPhNPh_2$ (I) was drawn from the following observations: (the values give the % I and the f. p.) 20, 107.8° ; 30, 123.8° ; 40, 134.8° ; 50, 144.8° ; 60, 152.7° ; 70, 159.7° ; 80, 165.6° ; 90, 171.6° ; 95, 174.6° ; 100, 176.7° . The progress of the transformation agreed closely with that of a unimol. reaction; the velocity coeffs. at different temps. are: (temp. and $k \cdot 10^3$ are given) 228° , 0.1-0.2; $246-7^\circ$, 1.6; 262° , 5.5; 272° , 11; 278° , 18; 282° , 23; $287-8^\circ$, 34; $292-3^\circ$, 45; the mean temp. coeff. between $246-292^\circ$ is 2.06 per 10° . The sp. cond. of the imino ether between $250-80^\circ$ was of the order 10^{-8} to 10^{-9} ; that of I was of the order of 10^{-6} to 10^{-7} at $250-80^\circ$. *N*-Phenylbenziminophenyl ether, m. 88° ; heated at $270-80^\circ$ for 1 hr., it yields *o*- ClC_6H_4NPhBz , m. $95-6^\circ$. The corresponding *p*- Cl deriv., pale yellow, m. $92-3^\circ$, undergoes transformation at $280-90^\circ$. *N*-*p*-Tolylbenziminophenyl ether, pale yellow, m. $65-6^\circ$; at $270-300^\circ$ this gives benzoyldi-*p*-tolylamine, m. $124-5^\circ$. From these results it is probable that the isomeric change of an imino ether into a substituted amide is not ionic in character. C. J. WEST

***o*-Tolunitrile and *p*-tolunitrile.** H. T. CLARKE AND R. R. READ. *Organic Syntheses* IV, 69-72(1925).—Diazotized *o*- $MeC_6H_4NH_2$, treated with NaOH and $NaCu(CN)_2$, gives 64-70% *o*- MeC_6H_4CN . Approx. the same yield is obtained in the prepn. of *p*- MeC_6H_4CN . C. J. WEST

***m*-Nitrobenzoic acid.** OLIVER KAMM AND J. B. SEGUR. *Organic Syntheses* III, 1(1923).—Crude *m*- $O_3NC_6H_4CO_2Me$, sapond. with NaOH, gives 87-93% of the acid. C. J. WEST

Methyl *m*-nitrobenzoate. OLIVER KAMM AND J. B. SEGUR. *Organic Syntheses* III, 71-2(1923).—Nitration of BzOMe gives 82-5% of the *m*- NO_2 ester. C. J. WEST

p-Nitrobenzoic acid. O. KAMM AND A. O. MATTHEWS. *Organic Syntheses* II, 53-5(1922).—*p*-O₂NC₆H₄Me is oxidized by Na₂Cr₂O₇ and H₂SO₄, giving 80-5% of *p*-O₂NC₆H₄CO₂H. C. J. WEST

p-Nitrobenzoyl chloride. ROGER ADAMS AND R. I. JENKINS. *Organic Syntheses* III, 75-7(1923).—O₂NC₆H₄CO₂H and PCl₅ give 90-6% of the chloride. C. J. W.

2,4,6-Trinitrobenzoic acid. H. T. CLARKE AND W. W. HARTMAN. *Organic Syntheses* II, 95-7(1922).—Oxidation of MeC₆H₂(NO₂)₃ with Na₂Cr₂O₇ and H₂SO₄ gives 57-69% of 2,4,6-(O₂N)₃C₆H₂CO₂H. C. J. WEST

Phenylacetic acid. ROGER ADAMS AND A. F. THAL. *Organic Syntheses* II, 63-5(1922).—PhCH₂CN is hydrolyzed by H₂SO₄, giving 80% of PhCH₂CO₂H. C. J. WEST

Ethyl phenylacetate. ROGER ADAMS AND A. F. THAL. *Organic Syntheses* II, 27-8(1922).—PhCH₂CO₂Et is obtained in 84-7% yields by boiling PhCH₂CN, EtOH and H₂SO₄. C. J. WEST

Benzyl cyanide. ROGER ADAMS AND A. F. THAL. *Organic Syntheses* II, 9-11(1922).—PhCH₂CN is obtained in 80-90% yields from PhCH₂Cl and NaCN. C. J. W.

p-Nitrobenzyl cyanide. G. R. ROBERTSON. *Organic Syntheses* II, 57-8(1922).—PhCH₂CN is nitrated at 10-20°, giving 50-4% of *p*-O₂NC₆H₄CH₂CN. C. J. W.

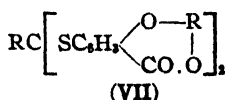

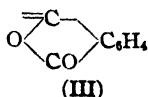

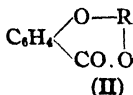

p-Nitrophenylacetic acid. G. R. ROBERTSON. *Organic Syntheses* II, 585, 615, 598-60(1922).—*p*-O₂NC₆H₄CH₂CN is hydrolyzed by H₂SO₄, giving 92-3% of *p*-O₂NC₆H₄CH₂CO₂H. C. J. WEST

p-Aminophenylacetic acid. G. R. ROBERTSON. *Organic Syntheses* III, 11-2(1923).—O₂NC₆H₄CH₂CO₂H is reduced by (NH₄)₂S and the product acidified with AcOH, giving 83-4% of H₂NC₆H₄CH₂CO₂H. C. J. WEST

m-Nitrocinnamic acid. F. K. THAYER. *Organic Syntheses* V, 83-4(1925).—*m*-O₂NC₆H₄CHO, AcONa and Ac₂O give 74-7% *m*-O₂NC₆H₄CH:CHCO₂H. C. J. W.

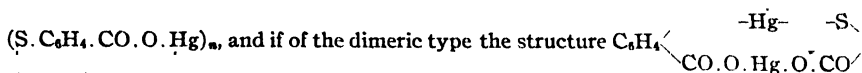

Constitution of Indian kamala. I. SIKHIBHUSHAN DUTT. *J. Chem. Soc.* 127, 2044-52(1925).—Rottlerin (I), m. 206-7°, mol. wt. in boiling PhMe, 585, 615, 598, is obtained in about 9 g. yield by extg. 150 g. com. kamala with C₆H₆. It dissolves to the extent of about 12% in boiling PhMe and C₆H₁₁OH. *Hepta-Ac deriv.* (II), m. 165°; the pale yellow *dibromide*, m. 115°; *hexa-Bz deriv.*, light yellow powder, does not m. below 300°; *hexa-MeO deriv.* (III), pale yellow, m. 135-7°, which yields an *Ac deriv.*, m. 215-7°, whose pale yellow *dibromide* decomps. on melting. Fuming HNO₃ oxidizes I to *p*-O₂NC₆H₄CH:CHCO₂H, (CH₂CO₂H)₂ and AcOH if the temp. is kept below 0°; if the reaction is allowed to warm up, *p*-O₂NC₆H₄CHO and *p*-O₂NC₆H₄CO₂H also are formed. Dil. HNO₃ (72 hrs. on the H₂O bath) gives AcOH, BzOH, *p*-O₂NC₆H₄CO₂H, small amts. of *o*-C₆H₄(CO₂H)₂ and *p*-C₆H₄(CO₂H)₂. Alk. KMnO₄ gives AcOH, BzOH, *o*- and *p*-C₆H₄(CO₂H)₂, (CO₂H)₂ and a dibasic acid, C₁₄H₁₀O₄, m. 192°. Alk. H₂O₂ gives the same products. Fusion with KOH gives AcOH, BzOH and 1,3,5-C₆H₃(OH)₃. Reducing agents (Zn and NaOH, Sn and HCl) give AcOH, (CH₂CO₂H)₂, PhCH₂CH₂CO₂H and a tarry residue yielding 1,3,5-C₆H₃(OH)₃ on fusion with KOH. HI and red P gave a hydrocarbon fraction, probably PhPr. Distg. with Zn dust gave β-C₁₄H₁₁Me and a liquid product, b. 230-40°. Oxidation of II with KMnO₄ gives AcOH, BzOH, (CO₂H)₂ and 1,3,5-(AcO)₃C₆H(CO₂H)₂, m. 260-70°. Oxidation of III with KMnO₄ gives the corresponding 1,3,5-(MeO)₃C₆H(CO₂H)₂, m. 248-50°. C. J. WEST

Substituted salicylic acids. V. Substituted salicylic phthalidene ether esters. H. P. KAUFMANN AND E. ROSSBACH. *Ber.* 58B, 1556-60(1925); cf. C. A. 18, 3051.—HOC₆H₄CO₂H and *o*-C₆H₄(COCl)₂ (I) in PhNMe₂ give 80% of salicylic phthalidene ether ester (II, R = III), m. 158.5°, identical with the product obtained from HOC₆H₄CO₂Na and I in C₆H₆. *Thiosalicylic phthalidene ether ester*, similarly obtained from HSC₆H₄CO₂H or its Na salt, m. 230°, is decompd. by boiling alc. NaOH but not by aq. Na₂CO₃ or NaOH. 2,5-HO(NCS)C₆H₃CO₂H (IV), m. 167-8°, is obtained in 73% yield from the 5-NH₂ acid (V) by the Sandmeyer method; with Zn dust in Na₂CO₃ 5 g. gives 4 g. 5-mercaptosalicylic acid (VI), m. 148°. *Bissalicylic acid 5,5'-disulfide*, m. 245°, is obtained in 85% yield from VI boiled in Na₂CO₃ in the air, 50% yield from diazotized V with S and Na₂S in NaOH, and 12 g. yield from 2 g. IV in NaOH at room temp. *Phthalidene ether ester* of IV (2.1 g. from 1.9 g. IV), orange-yellow, m. 199°. VI (3.4 g.) with 1.5 mols. I in PhNMe₂ gives 2.9 g. of *phthalidene-bis-4-[salicylic phthalidene ether ester] dithioether* (VII), amorphous, decomp. above 200°.

C. A. R.

Mercury compounds of thiosalicylic acid. GEORG SACHS AND HEINRICH BLESSL. *Ber.* 58B, 1493-9(1925); cf. C. A. 18, 3154; Smith and Semon, C. A. 18, 2115; and earlier workers.—Mol. wt. detns. do not permit of detg. with certainty whether the compds. formed by Hg mercaptides with Hg salts have the monomol. structure, RSHgX , or the dimeric form, and S. and B. have therefore undertaken to det. if possible what is their "reaction formula," i. e., whether at the moment of reacting they behave like a monomeric or dimeric substance. $\alpha\text{-HSC}_6\text{H}_4\text{CO}_2\text{H}$ (I) should form a Hg compd. which, if of the monomeric type, would probably have the structure $\text{S.C}_6\text{H}_4\text{CO.O.Hg}$ or

C_6H_4 . The 1st expts. with HgO and $\text{Hg}(\text{OAc})_2$ gave ill-defined or non-homogeneous products. The course of pptn. reactions with various Hg salts was then followed by detg. accurately the amt. of acid set free and of Hg not used up; the results showed that HgCl_2 , $\text{Hg}(\text{CN})_2$ and $\text{Hg}(\text{OAc})_2$ react in only 1 way and practically completely according to the equations $\text{I} + \text{HgCl}_2 = \text{ClHgSC}_6\text{H}_4\text{CO}_2\text{H}$ (II) + HCl ; $2\text{I} + \text{Hg}(\text{CN})_2 = \text{Hg}(\text{SC}_6\text{H}_4\text{CO}_2\text{H})_2$ (III) + 2HCN ; and $\text{I} + \text{Hg}(\text{OAc})_2 = \text{S.C}_6\text{H}_4\text{CO.O.Hg}$ (IV). The

K salt of III does not visibly react with $\text{Hg}(\text{CN})_2$ but with $\text{Hg}(\text{OAc})_2$ gives $2\text{IV} + 2\text{AcOH}$. Unlike the above salts, HgO dissolves in alc. or aq. alc. I with formation of a mixt. of III and IV. All these compds. contain the Hg attached to the S and not to a C atom of the nucleus, for IV with I gives $(\text{SC}_6\text{H}_4\text{CO}_2\text{H})_2$. These facts do not establish, however, whether IV really has the structure given above or the dimeric structure, i. e., that of a Hg salt of III. It is sol. in alkalies, to be sure, although in dissolving many samples show a transient yellow color; in the solns. thus obtained the excess of alkali can be titrated back with phenolphthalein. It dissolves in NaCl and NaOAc and on cooling a part seps unchanged, the rest being pptd. by AcOH as II, which is also formed when the IV, immediately after its pptn. in the reaction between the K salt of III and $\text{Hg}(\text{OAc})_2$, is treated with HCl . From the soln. of IV in KCN , III can be liberated. Steinkopf and his co-workers have made it very probable, from a large amt. of exptl. material, that there is no fundamental difference between org. and other residues attached to Hg, yet, according to them, the purely org. and the mercaptide compds., in spite of their formal analogy, cannot be compared directly with each other. Thus, the complex mercaptides, when decompd. with NH_3 , behave abnormally; II gives, besides the NH_4 salt of III, the *mercuri-amine salt* (V), $\text{Hg}(\text{SC}_6\text{H}_4\text{CO}_2\text{HgNH}_2)_2 \cdot 2\text{H}_2\text{O}$. Possibly these compds. have the anhydride-like structure IV but at the same time valence forces between the Hg and S atoms of different mols. make their appearance with preformation of the skeleton of III and in passing from the solid state into an aq. soln. or a H_2O -sol. form, whether reaction will occur in the 1 or the other direction will depend upon which of the 2 forms persists. Extension of this view to EtSHgAc (VI) will explain its association in aq. soln., although the possibility is not excluded that the mols., insofar as they are present in the dimeric form, have the structure assigned to them by Smith and Semon. The mol. wt. of VI was found to increase from 435.4 for 0.2651 g. in 19.886 g. freezing H_2O to 763.3 for 4.1197 g. (calcd. for the dimeric form, 641.5). *Mercuribisthiosalicylic acid* (III), m. 256° . *Di-K and di-NH₄ salts*. *Cu salt*, amorphous, yellow, turned blue-green by alkalis. *Hydroxymercurithiosalicylic anhydride* (IV), amorphous, sensitive to light, sometimes crysts. when allowed to stand a long time under the alc. mother liquors; it can be obtained in pure form in yellowish microrodlets in 50% yield from I in alc. treated to incipient turbidity with H_2O , then slowly with 1.5 mols. $\text{Hg}(\text{OAc})_2$ in H_2O ; the resulting ppt. is boiled out with alc., then treated with $\text{NH}_4\text{OH} \cdot (\text{NH}_4)_2\text{CO}_3$ until the ppt. which sometimes forms redissolves, filtered and treated hot with AcOH to incipient turbidity. V decomps. 206° . C. A. R.

Action of halogens on 2,4-dimethylbenzoyl chlorides. WM. H. PERKIN, JR. AND J. F. S. STONE. *J. Chem. Soc.* 127, 2275-97(1925).—2,4- $\text{Me}_2\text{C}_6\text{H}_3\text{Ac}$ is best prepd. by warming a mixt. of 100 g. FeCl_3 , 100 g. $m\text{-C}_6\text{H}_4\text{Me}_3$ and 84 g. AcCl until evolution of HCl ceases. Oxidation of this at 0° with NaOBr gives a good yield of 2,4- $\text{Me}_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$; if the temp. is allowed to rise, some 6-Br deriv. is formed. *Me ester*, m. -2 to -1° , b_{760} $232-3^\circ$. The chloride b_{15} $113-5^\circ$, b_{760} $234-6^\circ$, m. 25.5° ; bromination in the sunlight or in ultra-violet light gives about 50% of 2-bromomethyl-4-methylbenzoyl bromide (I), b_{15} $169-71^\circ$ (this probably contains some 4- BrCH_2 deriv.); it decomps. rapidly in moist air. Anhyd. HCO_2H and I at 15° give the free acid, m. $143-5^\circ$ (decompn.); *Me ester*, m. $62-3^\circ$, from I and MeOH ; its vapor is very irritating and causes prolonged

sneezing. Upon boiling the ester, it loses MeBr, giving 4-methyl-1,2-phthalide, m. 117-8°; soln. in NaOH followed by acidification gives 2-hydroxymethyl-4-methylbenzoic acid, m. 132-3°, with regeneration of the phthalide. If the crude I is converted into the Me esters and boiled, the pure I seps. as the phthalide, and the filtrate yields the isomeric 4-Br ester, m. 55-6°. This is hydrolyzed by boiling KOH, giving 4-hydroxymethyl-2-methylbenzoic acid, m. 141-2°; there is also formed a small amt. of 4,4'-dicarboxy-3,3'-dimethyldibenzyl ether, m. 221-2° (loss of 11H₂O from 2 mols. acid); mol. wt., 317 (Rast's method). Bromination of 2,4-Me₂C₆H₃COBr at 150-90° in the light of a Hg lamp, gives 40-50% of 2,4-di[bromomethyl]benzoyl bromide, viscid, green sirup, b₁₆ 223-8°; the acid (II), m. 158°; the Me ester, m. 83-4°; its vapors are very pungent, cause sneezing and burn the skin. Upon boiling, the Me ester gives 4-bromomethyl-1,2-phthalide, m. 159°; boiled with CaCO₃ and H₂O, it yields 4-hydroxymethyl-1,2-phthalide (III), m. 124-5°, which, warmed with NaOH, gives 2,4-di[hydroxymethyl]benzoic acid, m. 145-6°. III, (CO₂H)₂ and EtOK give Et 4-hydroxymethyl-1,2-phthalideoxalate, m. 169-70°; in MeOH, FeCl₃ gives a deep violet color. II and KCN in dil. EtOH give 4-cyanomethyl-1,2-phthalide, m. 123-4°, which is transformed by H₂O₂ and NaOH into 1,2-phthalide-4-acetamide, m. 218-9° (slight decompn.), and is hydrolyzed by concd. H₂SO₄ to 1,2-phthalide-4-acetic acid, m. 161-2°. On adding PhNHNH₂ to the mother liquor of III, there results a yellow compd., m. 179-80°, probably the phenylhydrazone of CHOC₆H₃MeCO₂H. Chlorination of 2,4-Me₂C₆H₃COCl at 180-210° in ultra-violet light gives a const. b. mixt. (b₁₆ 184-6°) of the di- and tetra-Cl derivs., from which the following derivs. were prepd.: 4-Chloromethyl-1,2-phthalide, m. 143-4°. 2,4-Dialdehydobenzoyl acid (IV), m. 138-9°, by boiling with chalk and H₂O; there also is formed (10%) 4-aldehydo-1,2-phthalide, m. 159-60° (phenylhydrazone, lemon-yellow, m. 171-2°). Alkali gives 2-hydroxymethylterephthalic acid, which, heated at 100° for 1 hr., gives 4-carboxy-1,2-phthalide, m. 279-80°. Chlorination at 200-20° gives 60-70% of 2,4-di[dichloromethyl]benzoyl chloride (V), b₁₀ 192-3°; the free acid (VI), m. 159-60°; anilide, m. 159°; Me ester, b₁₂ 186-8°; on boiling it gradually loses MeCl, yielding 4-dichloromethyl-1,2-chlorophthalide, b₁₃ 297°. Boiling V with chalk and H₂O gives IV, m. 140-1° (70% yields); dianilino deriv., m. 208°; condensation of VI with PhNH₂ gives anhydro-2,4-dialdehydobenzoic acid diphenylhydrazone, canary-yellow, m. 264-6°. VI and p-O₂N-C₆H₄NHNH₂ in EtOH give 4-aldehydo-1,2-hydroxyphthalide p-nitrophenylhydrazone(?), m. 221-3°, then 236-7° and, after solidifying, at 180°. In AcOH, there appears to be formed an Ac deriv. of the above, orange, m. 235°. In hot PhNO₂ there appears to be formed the orange dinitro deriv. of the anhydrodiphenylhydrazone, O₂NC₆H₄N₂H:CHC₆H₃:CH:N.N(C₆H₄NO₂) N CO, m. 295° (decompn.). The forma-

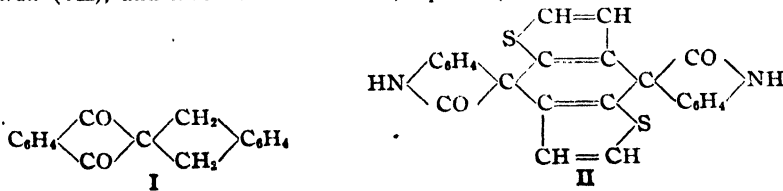

tion of 65-70% of pentachloro-2,4-dimethylbenzoyl chloride, b₁₄ 191-2°, is complete after 3.25 hrs. at 220°. Boiled with chalk, this gives 2-aldehydoterephthalic acid (VII), m. 242°, which is converted by boiling 25% NaOH into 4-carboxy-1,2-phthalide. Anhydro-2-aldehydoterephthalic acid phenylhydrazone, m. 326-7°. NH₂OH gives with VII the oxime, decomp. 136° and gives the imide of trimellitic acid. The filtrate from VII contained 2,4-(CHO)₂C₆H₃CO₂H, trimellitic acid and 4-aldehydo-1,2-phthalic acid, isolated as the phenylhydrazone, m. 174°, whose hydrate, yellow, m. 118°; heating to 115° converts this into the anhydride, orange-red, m. 216-7°. 2,4-Di[trichloromethyl]benzoyl chloride (VIII), b₁₅ 192-6°, does not fume in moist air, and reacts slowly with HCO₂H to give the acid, m. 170-1°; anilide, m. 202-3° (decompn.); amide, m. 175-6° (evolution of HCl). Me ester, b₁₅ 210°, pungent and lachrymatory on warming. 4-Trichloromethyl-1,2-phthalyl chloride, b₁₂ 186-7°. Dianilide, m. 220°. While VIII is very resistant to HCO₂H, it is readily hydrolyzed by boiling with chalk and H₂O, giving almost quant. trimellitic acid, whose Ca salt crysts. in feathery needles, sparingly sol in boiling and almost insol. in cold H₂O.

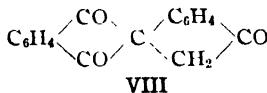

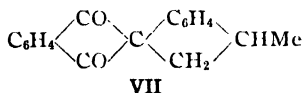

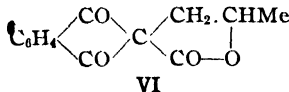

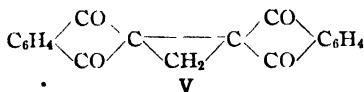

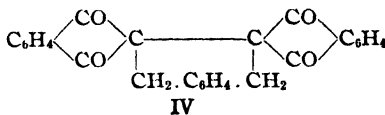

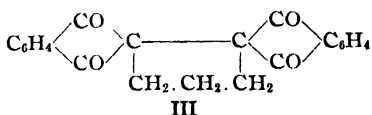

Acetylmandelyl chloride. F. K. THAYER. *Organic Syntheses* IV, 1-2 (1925).—PhCH(OH)CO₂H is treated with AcCl and then with SOCl₂, giving 79-83% of PhCH(OAc)COCl.

β-Methylesculetin (6,7-dihydroxy-4-methyl-1,2-benzopyrone). E. B. VLIET. *Organic Syntheses* IV, 45-6 (1925).—AcCH₂CO₂Et and 1,2,4-C₆H₃(OAc)₃, heated with 75% H₂SO₄ at 80°, give 92% of β-methylesculetin.

Phthalimide. W. A. NOYES and P. K. PORTER. *Organic Syntheses* II, 75-7 (1922).—C₆H₄(CO)₂O and NH₄OH or (NH₄)₂CO₃ give 94-5% of C₆H₄(CO)₂NH.

The constitution of phthalhydrazide. DAN RADULESCU and VICTOR GEORGESCU. *Bull. soc. chim.* 37, 881-90 (1925).—By the action of N₂H₄·H₂O (I) on phthalimide (II) in EtOH, Rothenburg (*Ber.* 29, 694 (1894)) obtained a substance, m. 250-6°, to which he assigned the formula III. Forsterling (*J. prakt. Chem.* [2] 51, 371 (1895)) obtained

M. A. YOUTZ

Nitration of phthal- and succin-*p*-tolil. O. L. BRADY, WM. G. E. QUICK AND W. F. WELLING. *J. Chem. Soc.* 127, 2264-7 (1925).—The system 2- and 3-nitro-*p*-toluidine shows the following f. ps., % of the 3-isomer being given: 0, 74.8°; 10.5, 69.0°; 18, 64.1°; 23.5, 60.3°; 29, 56.3°; 49.7, 74°; 55, 78.4°; 100, 116.7°; eutectic, 33.1, 56.1°; 38.7, 56.2°. Nitration of phthal-*p*-tolil by adding it to 10 times its wt. of HNO₃ (d. 1.5) at 0° and hydrolysis give a product contg. 76% 2,4-O₂N(H-N)C₆H₃Me. Since the eutectic was at 55.1°, there may be present small amts of di-NO₂ derivs. The main constituents were sepd. as the Ac derivs. The yield of mixed amines from succin-*p*-tolil was poor; it contains 84% of the 2-NO₂ deriv. Soln. of phthal-2-nitro-*p*-tolil in warm NaOH gives *phthal-2-nitro-p-toluidic acid*, decomp. about 160°. The corresponding *succin* deriv., m. 163°, if warmed above 50° with alkali, this undergoes further hydrolysis. 3-Nitrophthal-*p*-tolil, yellow, m. 149°; nitration gives a small yield of a mixt. of toluidines, contg. 83.5% of the 2-NO₂ deriv. *Tetrachlorophthal-p-tolil*, pale yellow, m. 145°, on nitration and hydrolysis, gives a product contg. 81.5% of the 2-NO₂ deriv. Nitration of succin- and phthalanil gives only *p*-O₂NC₆H₄NH₂. C. J. W.

Constituents of *Myoporum laetum*, Forst (the "ngaio"). I. P. H. McDOWALL. *J. Chem. Soc.* 127, 2200-7 (1925). Mannitol is present in the leaves of *Myoporum laetum*, Forst, to the extent of 0.2% (calcd. on the wt. of the green leaves), in the berries, which also contain HCO₂H, and in the wood to the extent of 0.25%. The leaves and terminal branchlets, distd. with superheated steam, give 0.12-0.30% of a volatile oil (varying with season and sample), from which, at -20°, there seps. C₃₂H₆₆ or C₃₄H₇₀, m. 62-3°, mol. wt. in C₆H₆, 470 (yield, 0.01% of the crude oil). The clear oil was reddish brown, with a sweet malt-like odor, d₂₀²⁰ 1.0203, [α]_D -26.54°, n_D²⁰ 1.4823, sapon. value, 17.9°. Repeated distn. gave *ngaione* (I) ("ny-one"), C₁₆H₃₄O₃ (analyses of derivs. agree closely with C₁₅H₃₂O₃), b₂₇ 182-3°, d₂₀²⁰ 1.0276, [α]_D -26.2°, n_D²⁰ 1.4804, mol. wt. in C₆H₆ and C₇H₄Br₂, 250. *p*-Nitrophenylhydrazones, bright yellow, m. 103°; the *thiosemicarbazone* is a thick reddish brown oil, which gives a yellow Ag salt. The I recovered from the salt analyzes for C₁₅H₃₂O₃, b₂₉ (cor.), d₂₀²⁰ 1.0273, n_D²⁰ 1.4794, [R]_L_D 69.10. I slowly reduces NH₄OH-AgNO₃ and Fehling soln., does not affect Schiff's reagent, gives a bright green fluorescence with *m*-C₆H₄(NH₂)₂ 2HCl in EtOH, but does not give a solid NaHSO₃ compd. *Oxime*, lemon-yellow, viscous oil, b₂₇ 201°, d₂₀²⁰ 1.0640, [α]_D -13.51° (10% in CHCl₃), n_D²⁰ 1.5008, [R]_L_D 73.37. *Semicarbazone*, m. 120-2° (decompn.). The phenylhydrazones and *p*-bromophenylhydrazones are liquid. I is probably a ketone, since it does not react with the usual aldehyde reagents. Na and EtOH reduce I to *ngaio* (II), C₁₅H₃₄O₃, b₂₉ 195-6° (cor.), d₂₉²⁰ 1.0163, [α]_D -25.00°, n_D²⁰ 1.4784, [R]_L_D 70.28, mol. wt. in C₆H₆, 260. CrO₃ does not regenerate I. II gives a mobile, light yellow liquid *Me xanthate*. The *acetate* b₂₉ 190-2°, d₂₀²⁰ 1.0337, n_D²⁰ 1.4720, [R]_L_D 79.60. *Me ether*, light yellow oil, b₂₉ 182° d₂₀²⁰ 0.9913, n_D²⁰ 1.4701, [α] -16.82°. MeI does not react with the K salt of this ether. C. J. WEST

Action of metals on dipentene dihydrohalide. Preparation of a synthetic diterpene. K. C. ROBERTS. *J. Chem. Soc.* 127, 2451 (1925). -EtOH solns. of *cis*- and *trans*-dipentene di-HBr and of *trans*-dipentene di-HCl were shaken with mol. Ag and finely divided Cu at room temp. until reaction was complete. In no case was metal halide formed. The dipentene formed polymerized to a *diterpene*, highly viscous liquid with a faint terpene-like odor, b₁₃ 173-83°, n_D²⁰ 1.5170, d₂₀²⁰ 0.9361, I value 103. C. J. W.

Borneol in spruce turpentine. A. S. WHEELER AND C. R. HARRIS. *J. Am. Chem. Soc.* **47**, 2836-8(1925); cf. *C. A.* **19**, 3087.—The residue of spruce turpentine after distg. the *p*-cymene fraction contains about 2% of borneol, isolated by cooling the fraction b_3 70–80° to –10°; from its $[\alpha]_D^{20}$ of –13.64° it is calcd. to contain about 36% of *l*-borneol; since the value is const. in different solvents, the product is free of isoborneol. Borneol obtained from a similar source in northern Europe contained 14–22% *l*-borneol.

C. J. WEST

Action of formic acid on certain sesquiterpenes. J. M. ROBERTSON, C. A. KERR AND G. G. HENDERSON. *J. Chem. Soc.* **127**, 1914-6(1925).— β -Caryophyllene, $b_{9.7}$ 118–9°, n_D^{17} 1.5009, d_4^{17} 0.9052, heated with an equal amt. of HCO₂H for several days, gives about 35% of *caryophyllene formate*, C₁₅H₂₆O₂, b_{110} 141–5°, d_4^{17} 1.22, n_D^{20} 1.4967, $[\alpha]_D^{17}$ –10.46°; the other fractions, b_{110} 115–30°, consisted mainly of hydrocarbons. Cadinene and HCO₂H give an unsatd. *hydrocarbon* (or a mixt.), C₁₅H₂₄, b_9 118–24°, d_4^{17} 0.9086, n_D^{14} 1.5010, which does not form a stable HCl salt, and unchanged cadinene. Cedrene gives an unsatd. *hydrocarbon*, C₁₅H₂₄, b_9 114–8°, d_4^{20} 0.9333, n_D^{21} 1.4988, some unchanged cedrene and a small fraction of higher b. p., in which the presence of alc. compds. is suspected.

C. J. WEST

Carboxycamphoronic acids. MAHIN SINGH AND RAM SINGH. *J. Chem. Soc.* **127**, 1966-8(1925).—Camphoric anhydride and the H₂NC₆H₄CO₂H (equal amts.) are heated with fused AcONa. *2'-Carboxycamphoronic acid*, (125–30° for 3 hrs.), crystals with 3H₂O, m. 75–80°, solidifies and then m. 199–200°, $[M]_D$ MeOH, c 0.0798, 18°, –584°; EtOH, c 0.0974, 17°, –574°; Me₂CO, c 0.1624, 17°, –551°; MeEtCO, c 0.1294, 17°, –390°. The *3'-deriv.* (160°, 3 hrs., quant. yield), is an amorphous powder, m. 249°; $[M]_D$ MeOH, c 0.1309, 19°, 466°; EtOH, c 0.0962, 17°, 431°; Me₂CO, c 0.1084, 412°; MeEtCO, c 0.0714, 17°, 313°. The *4'-deriv.* (140–5°, 4 hrs., 95% yield), amorphous mass with 11H₂O, m. 149–50°, then 212°; $[M]_D$ MeOH, c 0.0744, 19°, 860°; EtOH, c 0.1155, 17°, 722°; Me₂CO, c 0.1016, 17°, 709°; MeEtCO, 0.0820, 17°, 555°. The rotatory power is lowest in the solvent which has the lowest dielec. const.

C. J. W.

Derivatives of *m*- and *o*-dicresols. WILHELM STEINKOPF, ERICH ZEMISCH, HILDEGARD WINKLER AND GERHARD POHL. *J. prakt. Chem.* **110**, 354-8(1925).—Diazotized *m*-tolidine, heated with concd. HNO₃, gives 97% of *3,5,3',5'-tetranitro-4,4'-dihydroxy-2,2'-diolyl(?)*, yellow, m. 299°; NH₄ salt, dark yellow; Na salt, reddish yellow. Reduction by HCl and Sn gives the *tetraamino deriv.*, isolated as the *chlorostannate*, C₂₈H₃₀N₈ 8HCl SnCl₄, yellowish white, which gives with AcO the *tetraacetylamino deriv.*, crystals with 2H₂O. Di[nitro-*o*-cresol], reduced by HCl and Sn, gives *3,5'-diamino-4,4'-dihydroxy-3,3'-diolyl-HCl*, decomps 230°. PhNH₂ HCl SnCl₄ and α -C₁₀H₁₇NH₂ HCl SnCl₄ may be diazotized; the diazo compds. behave normally.

C. J. WEST

Di-*p*-tolylethane (unsym.). J. S. REICHERT AND J. A. NIEBUWLAND. *Organic Syntheses* **IV**, 23-5(1925).—A soln. of 700 cc PhMe, 70 cc. concd. H₂SO₄ and 7 g. HgSO₄, treated with C₂H₂, gives 60–4% of (MeC₆H₄)₂CHMe.

C. J. WEST

Benzilic acid. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses* **I**, 29-32 (1921).—Prepn. of Ph₂C(OH)CO₂K from Bz₂ and KOH.

C. J. WEST

Diphenylacetic acid. C. S. MARVEL, F. D. HAGER AND E. C. CAUDLE. *Organic Syntheses* **III**, 45-6(1923).—Ph₂C(OH)CO₂H is reduced by red P and I in glacial AcOH, giving 94–7% Ph₂CHCO₂H.

C. J. WEST

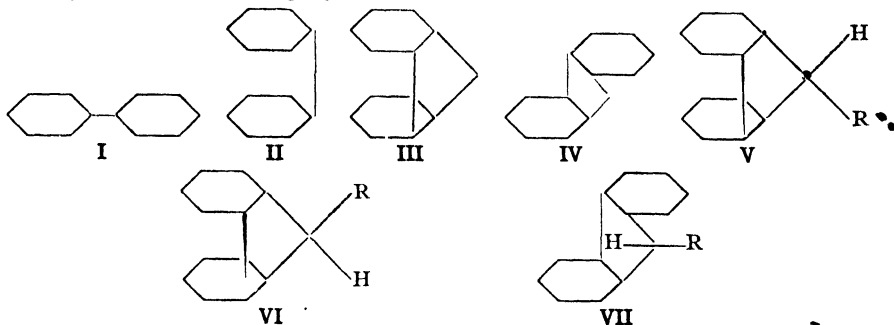

***p*-Dimethylaminodiphenylacetic acid.** DALIP SINGH. *J. Chem. Soc.* **127**, 2445-9 (1925).—Vorlander and Siebert (*Ber.* **39**, 1024(1906)) found that on distn. of (PhCHCO₂)₂Ba there resulted, among other products, Ph₂C:C:CPh₂; Me₂NC₆H₄CHPhCO₂H (I) was therefore prepd. since this might give rise to Me₂NC₆H₄CHPh:C:C(C₆H₅NMe₂)Ph, which would be a suitable material for testing van't Hoff's view of the mol. asymmetry of compds. of the substituted allene type. Me₂NC₆H₄COCO₂Et (2.5 mols.) and PhMgBr, if the product is worked up immediately, give the *Et ester*, m. 96–7°, of *p*-dimethylaminobenzilic acid (II), m. 50–5°, which is unstable and changes to yellow and then green on standing. A by-product of the ester, especially if a large excess of PhMgBr is used, is *p*-dimethylaminotetraphenylethyleneglycol, m. 193–4°. Reduction of II with HI and red P gives *p*-dimethylaminodiphenylacetic acid (I), m. 104–5°. Dry distn. of its Ba salt in a high vacuum gives *di-p*-dimethylaminobenzohydril ketone, m. 190°, and Me₂NC₆H₄CH₂Ph. No allene deriv. was found. (CO₂Et)₂. 4-C₆H₄NCH₂Ph and EtOK give about 33% of *Et phenyl-4-pyridylpyruvate* (III), yellow, m. 123–4°. The free acid is unstable and difficult to purify; the product obtained turned green at 100° and m. indefinitely at 110°; its *oxime HCl salt*, m. 52–3°. The Na salt is oxidized by H₂O₂ to Na phenylpyridylacetate; the free acid immediately decomps. into C₆H₄N-

CH_2Ph and CO_2 . **III** and $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ give *2- α -pyridylbenzyl-3-quinoxalone*, m. 294-5°. C. J. WEST

p-Toluy-*o*-benzoic acid. L. F. FIESER. *Organic Syntheses* **IV**, 73-5(1925).— $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ and PhMe are condensed by AlCl_3 , giving 96% of *p*- $\text{MeC}_6\text{H}_4\text{COC}_6\text{H}_4\text{CO}_2\text{H}$ (*o*). C. J. WEST

Stereochemistry of aromatic compounds; isomerism of the 9-aminofluorenes. RICHARD KUHN AND PAUL JACOB. *Ber.* **58B**, 1432-40(1925).—Cotton and Mouton have shown that certain isotropic liquids (especially C_6H_6 and its derivs.) are doubly refractive in a magnetic field, while aliphatic and hydroaromatic compds. show such a phenomenon either not at all or only very weakly; this peculiarity of aromatic compds. is probably to be explained by the existence of a magnetic moment and by a property of the mols. of easily arranging themselves in certain directions. It is as yet not possible to formulate definite conceptions as to the nature of the forces which, in the absence of powerful external fields, will lead to the arrangement in certain directions of the mols. of C_6H_6 derivs. but it may be assumed that the tendency to assume such directions with respect to each other is not limited to C_6H_6 nuclei of different mols. but is also present when the 2 nuclei are in one and the same mol. As regards the existence of geometrical isomers in the aromatic series there are then 2 possibilities: (1) The C_6H_6 nuclei repel each other, i. e., the axes perpendicular to the plane of the ring stand as far apart as possible from each other; the plane arrangement of the mols., as represented in our classical formulas (**I**), is retained and there are no isomers. (2) The C_6H_6 nuclei attract each other, i. e., the axes perpendicular to the plane of the ring approach each other, which is possible only if the mol. is deformed and the coplanar arrangement of the nuclei is abandoned. Formula **II** shows the closest possible approach of the 2 nuclei to each other; the axes perpendicular to the ring plane coincide. This holds on the assumption that the diphenyl union, corresponding to the ethane union, can rotate freely either about an axis in the plane of one of the nuclei or about an axis perpendicular to it. If this rotation is for any reason impeded or prevented the final configuration will depend on the resistance which the mol. **I** will have to overcome in its effort to pass into **II**. Just as the diphenyl may be compared with the ethane union, so a double union between C_6H_6 nuclei, as in diphenylene, fluorene, dihydroanthracene, etc., may be compared with the ethylene union, i. e., *cis-trans* isomers of fluorene, e. g. (**III** and **IV**), may be expected. All C_6H_6 -nucleus monosubstitution products of **III** or **IV** may exist in optically active antipodal forms, while disubstitution products with the same substituent in the 1,8-, 2,7-, 3,6- or 4,5-positions are identical with their mirror images, and the same is true of tetra-, hexa- and octasubstitution products with the same substituents in the above positions, but if the substituents in these positions are different the mirror images will again not be identical. Of the 9-substitution products, however, 2 non-resolvable forms (**V** and **VI**) can be derived from **III** and one resolvable form (**VII**) from **IV**. There are, therefore, 5 theoretically possible stereoisomeric 9-derivs., 2 *cis*- and 1 racemic and 2 optically active *trans*-forms. These views also hold when the C_6H_6 nuclei are not parallel to each other; if the angles between the planes of the 2 nuclei and the plane of the union between them are both greater or smaller than 90° the compd. will not be resolvable, but if 1 angle is greater, the other smaller than 90°, the compd. will be resolvable. The resolvability of the *trans*- and non-resolvability of the *cis*-forms is, moreover, independent of whether or not the 5-ring is plane, and 9 derivs. which also have a substituent in one C_6H_6 nucleus are likewise resolvable even when the 2 C_6H_6 nuclei lie in the same plane, as the 9-C atom is then asym. To test the above views, K. and J. have undertaken a study of 9-aminofluorene (**VIII**), which should exist in 3 inactive forms (**V-VII**). Reduction of fluorenone oxime according to Schmidt and Stutzel (*C. A.* **2**, 2232) gives a 9-aminofluorene (**IX**), m. 64°, probably identical with their α -compd. for which they give 53-5° as the m. p.; when pure, it dissolves in cold concd. H_2SO_4 without the slightest green color and melts colorless. A pure β -compd., m. 123°, could not be obtained by the S. and S. method; the 120-6° fraction of the crude bases contains CO_2 and gives with HCl and Me_3NCOCl derivs. identical with those obtained from **IX**. Kerp's compd. (**X**), m. 161° (*Ber.* **29**, 231 (1896)), was obtained in a single instance by extg. the crude bases with AcOEt and is apparently a *carbamnic acid*, $(\text{C}_6\text{H}_5)_2\text{CHNHCO}_2\text{H}$, corresponding to γ -9-aminofluorene (**XI**); with HCl it evolves CO_2 and gives a HCl salt entirely different from that of **IX** and having the m. p., 216°, of Wieland's **VIII**. HCl (*C. A.* **5**, 3414); with $\text{C}_6\text{H}_5\text{N}$ and Ac_2O , **X** likewise loses CO_2 and gives the *Ac deriv.*, m. 245.5-6.0°, of **XI**; with concd. NH_4OH , **X** gives **XI**, m. 60°, prisms which absorb CO_2 with exceeding rapidity and which have, therefore, not yet been obtained pure. **XI** reacts with AcOH considerably more easily than **IX** and is therefore obtained in considerable amts. as its *Ac deriv.* when the fluore-

none oxime or ketazine is reduced in boiling AcOH with Zn; in the reduction of the oxime with Na-Hg it is not formed. Its Ac deriv. gives fluorene on distn. with Zn dust, and with HNO_3 (d. 1.35) yields the same 1,8-dinitrofluorene, m. 196–7°, as S. and S. obtained from IX. IX and XI both give the same color reaction with triketohydrindene hydrate and a blue color with hot concd. H_2SO_4 but differ characteristically from each other in their behavior towards CO_2 and AcOH. IX. HCl, m. 255°; Ac deriv., m. 262° (cor.); α -N,N-dimethyl-N'-9-fluorenylurea, from IX and Me_2NCOCl in Et_2O , m. 158–9°, colored blue by even cold concd. H_2SO_4 .

Triphenylmethane. J. F. NORRIS. *Organic Syntheses* IV, 81–3(1925).— C_6H_6 , CCl_4 and AlCl_3 give the complex $\text{Ph}_3\text{CCl} \cdot \text{AlCl}_3$, which is decompd. by Et_2O to give 68–84% Ph_3CH C. A. R.

“Triphenylcarbinol hydrochloride.” BURCKHARDT HELFERICH AND HANS DEHE *Ber.* 58B, 1605(1925).—The substance $\text{C}_{19}\text{H}_{17}\text{OCl}$, m. 174°, obtained by the action of H_2O on Ph_3CCl in $\text{C}_6\text{H}_5\text{N}$ (C. A. 19, 2479) is also formed when HCl gas is passed into Ph_3COH in $\text{C}_6\text{H}_5\text{N}$; yield, 5 g. from 5 g. Ph_3COH . The “basic” properties of the O in the carbinol must therefore be quite pronounced. C. J. WEST

Reactions of compounds of triphenylmethyl and triphenylsilyl in liquid ammonia. C. A. KRAUS AND RAPHAEL ROSEN *J. Am. Chem. Soc.* 47, 2739–48(1925).—Na and K derivs of Ph_3C are salts; for 0.05 and 0.08 N, the equiv. cond. in liquid NH_3 is 64 and 32, resp. Ph_3CH does not conduct appreciably in liquid NH_3 . $(\text{Ph}_3\text{C})_2\text{O}$ and Na_2O or K_2O are obtained as final products after oxidation of the corresponding salts in liquid NH_3 . There is evidence of the existence of intermediate products. $\text{Na}(\text{K})\text{-CPh}_3$ are formed by the action of the corresponding amide on Ph_3CH in liquid NH_3 . The reaction is reversible and hydrolysis of the salts is obtained under suitable conditions. The K salt crysts. free from NH_3 and the Na salt with 1 mol. NH_3 . Ph_3CH is a sensitive indicator in liquid NH_3 , being red in alk. and colorless in acid soln. Ph_3CCl is slightly hydrolyzed in liquid NH_3 . The reaction is reversible and Ph_3CCl is formed by the action of NH_4Cl on Ph_3CNH_2 . Ph_3CCl is hydrolyzed to the amine and NH_4Cl on evap. an NH_3 soln. of the compd. and on treating the compd. with NH_3 vapors at higher temps. Ph_3CCl forms an addn. compd. with 1 mol. $\text{C}_6\text{H}_5\text{N}$, m. 173–4°, and with PhNH_2 , m. 189–90°. Ph_3CNH_2 does not react with KNH_2 . With K it yields Ph_3CK and KNH_2 . The Ph linkage is broken down when Ph_3SiCl is reduced with metallic Na in liquid NH_3 ; definite compds. could not be isolated. Ph_3SiCl hydrolyzes in liquid NH_3 with the formation of Ph_3SiNH_2 and NH_4Cl . The sp. cond. of Ph_3SiCl in the fused condition is 2.2×10^{-6} reciprocal ohms. C. J. WEST

Absorption spectra of benaurin. W. R. ORNDORFF, R. C. GIBBS AND S. ALICE McNULTY. *J. Am. Chem. Soc.* 47, 2767–77(1925).—The exptl. method used in measuring absorption spectra and the precautions taken to insure accurate and reliable data are outlined. Curves showing the absorption spectra of solns. of benaurin in neutral EtOH , EtOH-HCl , 93% H_2SO_4 , EtOH-alkali and 33% aq. alkali and of $(p\text{-HOCH}_2)_2\text{-CHPh}$ in neutral EtOH are recorded and discussed. It is suggested that the absorption spectra of benaurin in neutral alc. are due to the presence of a quinonoid hydrate form of benaurin, in acid soln. to a benaurin salt of the acid, in the alk. (KOH) soln. to the quinonoid K salt and in the strongly alk. (33% KOH) soln. to the di-K salt of the carbinol. A table showing the position of max. absorption, expressed in frequency nos., for all the bands in each of the solns. studied, is given. C. J. WEST

Benzoïn. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses* I, 33–4(1921).—Prepn. of $\text{PhCH}(\text{OH})\text{Bz}$ from BzH and NaCN . C. J. WEST

Benzil. ROGER ADAMS AND C. S. MARVEL. *Organic Syntheses I*, 25-7(1921).—Prepn of Bz₂ from PhCH(OH)Bz and HNO₃. C. J. WEST

Cleavage of ring systems. JAKOB MEISENHEIMER. *Ber.* 58B, 1491-2(1925).—Reply to Kuhn and Ebel (*C. A.* 19, 2477). C. A. R.

Novel inversion phenomena. J. BÖRSEKEN. *Ber.* 58B, 1470-3(1925).—Remarks on the paper of Kuhn and Ebel, *C. A.* 19, 2477. C. A. R.

Stability of hexasubstituted ethanes. A. P. GRAY AND C. S. MARVEL. *J. Am. Chem. Soc.* 47, 2796-802(1925).—Dicyclohexylphenylchloromethane, m. 122° in 67-70% yields from the carbinol and AcCl. Shaken with mol. Ag in PhMe for 35 hrs., it gives 75% of sym-tetracyclohexyldiphenylethane (I), b_{1.75} 170-1°, n_D²⁵ 1.6710, mol. wt. in boiling C₆H₆, 506, 470; it forms a faintly yellow, viscous liquid, stable in the air and showing no oxidation at 330° for 30 min. It does not solidify at 0° and does not absorb H in the presence of Pt. An excess of cyclohexyl-MgBr and Et hexahydrobenzoate gave dicyclohexylcarbinol and cyclohexene. Tri-tert-butylethynylchloromethane, m. 170-1°, in 28-44% yields from the carbinol and PCl₃ in PhMe; it is unstable and turns yellow or red on standing a few days, even in the dark; EtOH or H₂O accelerates the change. Heating in PhMe gives a yellow solid, m. 210-20°. With mol. Ag, Hg, Na-K, Zn or Mg in C₆H₆ or Et₂O, no reaction occurs, but in PhMe at 100°, Ag gives a product which absorbs about 50% of the calcd. amt. of O to form a peroxide, thus indicating the existence of a purely aliphatic free radical. The stability of I and the existence of tri-tert-butylethynylmethyl are in accord with Lewis' explanation of the existence of free radicals. C. J. WEST

Infra-red absorption spectra of molten naphthalene. F. K. BELLE. *J. Am. Chem. Soc.* 47, 2811-6(1925).—A simple elec. heating device for the examn. of the infra-red absorption of solids in the molten state is described. The infra-red absorption spectrum of C₁₀H₈ at 95° and of C₆H₆ have been examd. as far as 12.0μ. A comparison of these spectra reveals a pronounced similarity in the region of the shorter wave lengths as far as 5.5μ and beyond this point shows increasing dissimilarity as the longer wave lengths are approached. C. J. WEST

The stereoisomeric forms of decahydronaphthalene. WALTER HÜCKEL. *Ber.* 58B, 1449-52(1925).—In view of the large differences in the phys. consts. of the prepn. of trans-decalin (I) of Eisenlohr and Polenske (*C. A.* 19, 498) and those of H. (*C. A.* 19, 1269), H. has prepd. I like E. and P. by the Wolff method, starting with about 3 times as much trans-β-decalone semicarbazone and thoroughly purifying the I with concd. H₂SO₄. His product (about 4 g from 21 g semicarbazone) shows d₄²⁰ 0.8685, n_D²⁰ 1.4691, M_D 44.28, heat of combustion 10824 cal./g., in good agreement with his other prepn. and with that obtained by Zelinskii (*C. A.* 19, 1262) from com. decalin. The exply. detd. consts. are: b. 185°, d₄²⁰ 0.8703, n 1.46728, 1.46994, 1.47572, 1.48060 for α, D, β and γ at 18.2°. The extreme values of the consts. of H.'s numerous prepn. of cis-octalin, all prepd. by longer or shorter heating of cis-β-decalol with KHSO₄, are. d₄²⁰ 0.917 and 0.913, n_D²⁰ 1.4986 and 1.4911, M_D 43.55 and 43.32, EM_D 0.04 and -0.19. His homogeneous trans-Δ²-octalin m. -24°, d₄¹⁹ 0.8936, n_D¹⁹ 1.48429, M_D 43.64, EM_D 0.13. The discrepancies between the results of E. and P. and those of H. are ascribed to the fact that the Wolff, like the Clemmensen, method gives products contaminated with O-contg. substances, which must be purified with concd. H₂SO₄, moreover, in the trans-series E. and P. used too small amts. of material. C. A. R.

α-Bromonaphthalene. H. T. CLARKE AND ETHEL SCHRAM. *Organic Syntheses I*, 35-7(1921).—Prepn. of α-C₁₀H₇Br from C₁₀H₈ and Br₂. C. J. WEST

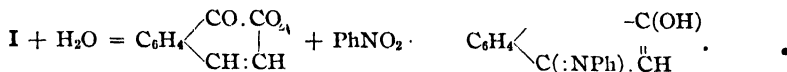

Nitroso-β-naphthol. C. S. MARVEL AND P. K. PORTER. *Organic Syntheses II*, 61-2(1922).—Technical β-C₁₀H₇OH with HNO₂(NaNO₂ and H₂SO₄) give 99% of 1,2-C₁₀H₆(OH)NO. C. J. WEST

1,4-Aminonaphthol hydrochloride. J. B. CONANT, R. E. LUTZ AND B. B. CORSON. *Organic Syntheses III*, 7-10(1923).—α-C₁₀H₇OH is combined with PhN₂Cl and then reduced, giving 65-74% of 1,4-C₁₀H₆(OH)NH₂·HCl. C. J. WEST

1,4-Naphthoquinone. J. B. CONANT AND S. A. FREEMAN. *Organic Syntheses V*, 79-82(1925).—1,4-C₁₀H₆(OH)NH₂·HCl, oxidized by Na₂Cr₂O₇ and H₂SO₄, gives 50-81% of 1,4-C₁₀H₆O₂. C. J. WEST

The preparation and properties of the arylaminonaphthoquinones. R. LANTZ AND A. WAHL. *Bull. soc. chim.* 37, 890-901(1925); cf. *C. A.* 19, 2487. —α-Halo-β-naphthols react readily with PhNH₂ to give phenylimino-1-hydroxy-2-naphthalene (I), which in Me₂CO is readily oxidized by the air and by oxidizing agents. In alk. alc. it is oxidized by dil. NaOCl at 5° to green crystals of 1-phenylimino-2-naphthoquinone (II), m. about 100° (yield, nearly 100%), identical with the reaction product of PhNO

on β -C₁₀H₇OH. It is reduced by Al-Hg to I. Similarly was obtained 1-*o*-methoxy-phenylimino-2-naphthoquinone and 1-*p*-acetylaminophenylimino-2-naphthoquinone. In soln. the blue-green colors of these substances fade, especially in presence of acid or alkali. If HCl is added to a soln. in Me₂CO and then AcONa, there is formed a red ppt. of 2-hydroxy-4-phenylimino-4-naphthoquinone:

PhNH₂ and II in Me₂CO give 1-phenylimino-4-phenylamino-2-naphthoquinone (III), brown crystals, and simultaneously more of II is reduced to 1-phenylimino- β -naphthol. III, also represented by its tautomeric form, 2-hydroxy-1,4-diphenylimino-1,4-naphthoquinone (IIIa), is changed by boiling in excess AcOH for 0.5 hr. to anilidonaphthoquinone-anilide (IV). III can be obtained directly from I without isolating II and in better yield by treating I with excess PhNH₂, adding Cu(OH)₂, and stirring with a current of air. This gives the Cu salt of the IIIa form, which is purified by recrystn. from PhNO₂. By treating II (40 g.) with 50–60 cc. of NaHSO₃ soln. (36° B \acute{e} .), finally with Na₂CO₃, filtering and acidifying, is produced 1-phenylamino-2-hydroxynaphthalenesulfonic acid (V). 1-*p*-Tolylamino-2-naphthoquinone behaves similarly but the acid formed (VI) is less stable and the salts are more sol. By sulfonating I is obtained an isomer of V. Similarly the 1-*p*-tolylamino-2-hydroxynaphthalene was sulfonated to give an acid isomeric with VI.

M. A. Youtz

Reaction of 2-benzylhydrindone phenylhydrazine with phenylhydrazine. HERMANN LEUCHS and KURT WINZER. *Ber.* 58B, 1520–7 (1925).—It was found (C. A. 7, 3329) that 2-benzyl-1-hydrindone (I) with excess of PhNHNH₂ at 130° gives a compd. C₂₈H₂₅N₃ (II). On treatment with Ac₂O, II loses a PhNHNH residue and yields a di-Ac compd. C₂₆H₂₃O₂N (III), in which one Ac group is firmly held while the other is so loosely bound that it is split off as AcOH by boiling with alics., forming the MeO and EtO derivs., C₂₆H₂₅O₂N (IV) and C₂₆H₂₅O₂N (V), of a mono-Ac compd.; reacylation of these compds. cannot be effected, but HCl, AcOH or even PhNHNH₂ hydrolyzes them to the same hydroxymonoacetyl compd., C₂₄H₂₁O₂N (VI), in which the HO group reacts with neither alics. nor Ac₂O and which contains no group reacting with PhNHNH₂; the Ac group remaining is, therefore, probably not attached to a C atom in ketone combination but to the N and the labile AcO group in III is part of an enolized C:O group in which it has replaced a PhNHNH residue, i. e., the following non-reversible reactions take place: C₂₁H₁₇(:NH)(:CNHNHPh) (II) (+ Ac₂O) \longrightarrow C₂₁H₁₇(:NAC)(COAc) (III) (+ MeOH) \longrightarrow C₂₁H₁₇(:NAC)(COMe) (IV) (+ HCl) \longrightarrow C₂₁H₁₇(:NAC)(COH) (VI). VI easily forms monohalogen derivs. in which the halogen is bound aromatically. II behaves with Bz₂O in the same way as with Ac₂O, but with C₆H₄(CO)₂O gives a monomol. compd. C₃₀H₂₁O₂N (VII) in which a new ring must have been formed; in order not to make it necessary to assume too large a ring, the \equiv C:O— and =N— residues in VII must be adjacent. This cyclic structure is probably the cause of the stability of VII towards HCl-AcOH and towards boiling MeOH, by which it is not attacked at all. With hot concd. HCl, II gives in good yield the HCl salt of a base C₂₂H₁₇N (VIII),

in whose formation it must be assumed that intramol. alkylation has occurred: Cl.C.

NH \longrightarrow C:N.HCl. VIII and its salt seem to have a tendency to add H₂O or HCl loosely at the double bond, which certainly can bind other mols. firmly. Thus, VIII with Ac₂O forms III, with C₆H₄(CO)₂O it gives VII in small part and with PhNHNH₂ at 130° it smoothly yields II. Boiling HCl smoothly converts the phenylhydrazone (IX) of I into VIII. HCl, and there can, therefore, be no doubt that when IX is heated with PhNHNH₂ at 130° there occurs a kind of indole synthesis and that the primary product immediately adds PhNHNH₂ to form II. It has not been possible up to the present to effect similar reactions with other than benzyl derivs. of hydrindone and it is, therefore, assumed that the ring formation occurs not through the tertiary α -C atom in IX but through the CH₂ group of the PhCH₂ residue, VIII being α,β -[*o*-benzylene]- γ -phenyl- β,γ -dihydroquinoline. II, m. 190–2°, from I and 4 parts PhNHNH₂ heated 8 hrs. at 130°, gives

an emerald-green soln. with $\text{H}_2\text{SO}_4\text{-FeCl}_3$, is unchanged by NH_3 in boiling MeOH, while boiling alc. NaOH converts it into products m. 190–206°. **III** (2.3–2.5 g. from 3 g. **II**), m. 155–7°, gives no color with alc. FeCl_3 . **IV**, m. 164–6°, dissolves in H_2SO_4 with a faint green-yellow color discharged by AcOH, gives no color with alc. FeCl_3 . **V**, m. 125–7°. **VI**, m. 196–8°. *Br deriv.* of **VI** (obtained from **III**, **IV** or **VI** with Br in AcOH through a reddish *perbromide*, m. about 170° (decompn.)), sinters 246°, m. 251–3°, insol. in alkalis. With Cl in AcOH, **III** gives, depending on the length of treatment, a *mono-* or a *di-Cl deriv.*, m. 238° and 265°, resp. *Di-Bz compd.*, $\text{C}_{26}\text{H}_{27}\text{O}_2\text{N}$, from **II** with Bz_2O and NaOBz at 100°, m. 191–3°, insol. in hot 2 N NaOH, sol. in H_2SO_4 with a yellow color turned faintly green by FeCl_3 (yield, 2.1 g. (together with 2.1 g. $(\text{PhNBz})_2$) from 3 g. **II**), converted by boiling MeOH into the *monobenzoylmethoxy compd.*, m. 163–4°. *Monobenzoyl compd.*, $\text{C}_{29}\text{H}_{23}\text{O}_2\text{N}$, m. 160–1°; *Br deriv.*, m. 208–9°, unchanged by boiling NaOEt. *Monophthalyl compd.* (**VII**) (0.23 g. from 2 g. **II** with $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ and NaOAc at 130°), m. 256–8°, sol. in H_2SO_4 with yellow color turned greenish by FeCl_3 . **VIII**, HCl (4 g. from 5 g. **II**), m. 206–8° (gas evolution); free **VIII**, prisms with H_2O from petroleum ether, m. 110–5° and, anhyd., 123–4°.

C. A. R.

Mesothianthracene derivatives. **II. Dianthranyl disulfide and dianthranyl tetrasulfide.** WM. H. COOKE, I. M. HEILBRON AND G. H. WALKER. *J. Chem. Soc.* 127, 2250–5(1925); cf. *C. A.* 17, 1465–9, 10- $\text{C}_{14}\text{H}_8\text{Br}_2$ and excess of NaHS (9 g. Na in 1000 cc. AmOH, sated with H_2S), boiled 12 hrs., give 40% of dianthranyl disulfide (**I**); if the stream of H_2S is continued during the boiling, the yield is less. The mother liquors contain *dianthranyl oxide*, straw-colored, m. 213°, which on reduction yields $\text{C}_{14}\text{H}_{10}$ and anthranol. The conditions for its formation are not sharply defined. If less than 1 equiv. of NaSH is used, there results 80–90% of dithioheptacyclene (**II**). Heating with a considerable excess of Na_2S gave only a little **I**, but on heating in an autoclave for 2 hrs. at 150°, there results a quant. transformation into **II**. Na_2S_2 in BuOH gives about 60% of **I**; with AmOH resin formation decreases the yield. Heating in an autoclave at 200° for 4 hrs. gives *ms-dibromodheptacyclene disulfide*, yellow amorphous product, which is resistant to EtOH-KOH. Na_2S_2 in AmOH, heated 2 days, gives 33% of *dianthranyl tetrasulfide*, m. 190° (previously termed dithiodianthrone disulfide); boiling with EtOH-NaOH for 3 hrs. converts it into **I**, 9-anthranyl mercaptan being an intermediate product.

C. J. WEST

Action of nitrogen dioxide on anthracene derivatives. E. DE B. BARNETT. *J. Chem. Soc.* 127, 2040–4(1925)—1- $\text{C}_{14}\text{H}_9\text{Cl}$ and NO_2 give an addn. product which, with cold $\text{C}_6\text{H}_5\text{N-EtOH}$, gives 1-chloro-9(or 10)-nitroanthracene, Au-yellow, m. 155°. 2- $\text{C}_{14}\text{H}_9\text{Cl}$ gives a viscous oil which yields a mixt. of NO_2 derivs. with $\text{C}_6\text{H}_5\text{N}$. 1,5-Dichloro-9,10-dinitro-9,10-dihydroanthracene, turns yellow on heating and m. 156° (evolution of gas); cold $\text{C}_6\text{H}_5\text{N-EtOH}$ give 1,5,9- $\text{C}_{14}\text{H}_7\text{Cl}_2\text{NO}_2$. The addn. compd. from 1,8- $\text{C}_{14}\text{H}_9\text{Cl}_2$ contains 1.5 CHCl_3 , m. 215° (evolution of gas). 9-Bromo-9,10-dinitro-9,10-dihydroanthracene, turns yellow and sinters at about 115°; $\text{C}_6\text{H}_5\text{N}$ and EtOH give 9,10- $\text{C}_{14}\text{H}_8(\text{NO}_2)_2$. 9,10- $\text{C}_{14}\text{H}_8\text{Br}_2$ and NO_2 give 9-bromo-9-nitroanthrone, sinters 116°. 9,10-Dichloro-9,10-dinitro-9,10-dihydroanthracene, extremely unstable and decomps. on boiling with CHCl_3 , giving $\text{C}_{14}\text{H}_8\text{O}_2$. The 1,5,9-tri-Cl deriv., yellow, decomps. 156° and yields with $\text{C}_6\text{H}_5\text{N}$ and EtOH 1,5-dichloro-9,10-dinitroanthracene, pale yellow, m. 277°. 2,3,9-Tribromo-9-nitroanthrone, evolves brown fumes on heating with PhMe and gives 2,3- $\text{C}_{14}\text{H}_6\text{Br}_2\text{O}_2$. Neither *meso-* nor *bz-*substituents have any appreciable influence on the ease with which addn. to the "bridge" takes place; *bz-*substituents do not increase the stability of the compds. formed by the addn. of NO_2 groups to the "bridge," whereas in the case of addn. of halogen atoms, the presence of Cl atoms in α -positions results in an enormous increase in stability; *ms-*substituents appear to decrease the stability of the addn. products.

C. J. WEST

9,10-Dibromoanthracene. I. M. HEILBRON AND J. S. HEATON. *Organic Syntheses* **III**, 41–3(1923).—Bromination of $\text{C}_{14}\text{H}_{10}$ in CCl_4 gives 83–8% 9,10- $\text{C}_{14}\text{H}_8\text{Br}_2$. C. J. W. **β -Methylanthraquinone.** L. F. FIESER. *Organic Syntheses* **IV**, 43–4(1925).—*p*- $\text{MeC}_6\text{H}_4\text{COC}_6\text{H}_4\text{CO}_2\text{H}$ (o), heated with fuming H_2SO_4 (20% SO_3), gives 86–95% of β - $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3\text{Me}$.

C. J. WEST

Furfural. ROGER ADAMS AND V. VOORHEES. *Organic Syntheses* **I**, 49–52(1921).—Prepn. of furfural from corn cobs, 10% H_2SO_4 and NaCl.

C. J. WEST

4-Ethylcyclopentane-3,5-dione. G. T. MORGAN AND A. E. RAWSON. *J. Soc. Chem. Ind.* 44, 462–3T(1925).—*Na acetylacetonone* (**I**) was prepd. in a 93% yield by adding CH_2Ac_2 to EtONa, cooling, washing and drying. 3-Ethylacetylacetonone (**II**) was prepd. in 60% yield by heating **I** with 6 times its wt. of EtI in an autoclave at 140–50° for 3 hrs. **II** was then refluxed with TeCl_4 in CHCl_3 ; on evapn. an 88% yield

of the 4-ethylcycloelluropentane-3,5-dione 1,1-dichloride (III) was obtained, blackening 185–90°. III was reduced at 0° with KHSO_5 in H_2O , yielding 96% of crude 4-ethylcycloelluropentane-3,5-dione, m. 141–2° after recrystn. from C_6H_6 . T. S. CARSWELL

Isatin. C. S. MARVEL AND G. S. HERS. *Organic Syntheses* V, 71–4 (1925).— PhNH_2 , NH_2OH and $\text{Cl}_3\text{CH}(\text{OH})_2$ with Na_2SO_4 give 80–91% of PhNHCOCH:NOH which, with concd. H_2SO_4 , yields about 70% isatin. C. J. WEST

4- and 6-Methylisatin. FRITZ MAYER AND RUDOLF SCHULZE. *Ber.* 58B, 1465–9 (1925).—As stated by Sandmeyer (*C. A.* 13, 1840), *m*- $\text{MeC}_6\text{H}_4\text{NHCOCH:NOH}$ (I) heated with concd. H_2SO_4 gives a mixt., m. about 143°, of 4- and 6-methylisatin (II and III, resp.), which M. and S. have now succeeded in sepg. into its components. On pouring it into H_2O without cooling, impure II first seps. and, later, impure III. Their degree of purity and their constitution can be detd. by degradation to the corresponding 6,2- and 4,2-Me(H_2N) $\text{C}_6\text{H}_3\text{CO}_2\text{H}$ (IV and V). True to rule, IV cannot be esterified with alc. and HCl while V can. Moreover, in their prepn from II and III with alk. H_2O_2 the 2 acids behave quite differently; V seps. on acidification of the soln. and is completely pptd. on further addn. of NaOAc , while IV can be isolated only as its Cu salt. The highest melting prepn. of II obtained m. 189° and on oxidation gave only pure IV, while no prepn. of III melting higher than 147° (softening 140°) could be obtained; this on oxidation gave a V contg. approx 10% IV. There seems to be no doubt, therefore, that Fincklee's product, m. 169° (*Ber.* 38, 3551 (1905)), was pure III. Bauer claims that his compd., m. 182°, gives *m*-homoisatoic acid on oxidation and is therefore III (*C. A.* 3, 2450), but M. and S. find that their method of oxidation yields both IV and V, so that B.'s substance is really impure II. C. A. R.

The (non-catalytic) hydrogenation of thionaphthene. R. FRICKE AND G. SPILKER. *Ber.* 58B, 1589–601 (1925); cf. *C. A.* 19, 1412.—The cor. const. for the new compds. obtained in the reduction of thionaphthene (I) with Na and alc., as described in the earlier paper, are: *o*- $\text{EtC}_6\text{H}_4\text{SH}$ (II), b_{768} 210.1–0.9°, d_4^{20} 1.0349; *o*- $\text{EtC}_6\text{H}_4\text{SMe}$ (III), b_{777} 228.2–8.6°, d_4^{20} 1.0253. Further study of the dark brown substance obtained from the Et_2O ext. of the reaction product has shown that it is a mixt. of unchanged I and 2,3-dihydrothionaphthene (IV), b_{768} 233.3–4.5° (cor.), d_4^{20} 1.1125, mol. wt. in freezing C_6H_6 125–9. They are sepd. from each other by removing the I as the picrate or by isolating the IV as the HgCl_2 compd., yellow, m. 128–9°. On further reduction IV gives II; it was also identified by conversion in AcOH with H_2O_2 into the sulfone, $\text{C}_8\text{H}_8\text{O}_2\text{S}$, m. 91.5–2.0°. II in AcOH with Cl gives *o*- $\text{EtC}_6\text{H}_4\text{SO}_2\text{Cl}$, converted by concd. NH_4OH into the amide (V), m. 126–6.5° (given in the literature as 97–100°); sulfonation of PhEt, followed by chlorination and treatment with NH_4OH , gave a mixt., sepd. by fractional crystn. of V, likewise m. 126°, and the *p*-isomer, m. 109°. The II was still further identified by prepg. it from *o*- $\text{EtC}_6\text{H}_4\text{SO}_2\text{Cl}$ with Sn and HCl . Reduction of I with Na in MeOH and (fermentation) AmOH gave practically the same results, as regards IV, as in EtOH , in MeOH 70 g. I yielded 8 g. IV and 10 g. II, in AmOH 12 and 22 g., resp. Two expts. were made on the reduction of solid I with H under pressure (in an autoclave which is described); in the 1st the initial pressure at room temp. was 50 atm. and reached 111 atm. at the max. temp. (438°), and in the 2nd the initial pressure was 70 atm. and reached 159 atm. at the max. temp. (425°). The results in the 2 expts. were almost the same; the products were H_2S , CH_4 and its homologs, C_6H_6 , PhMe, PhEt, II, I, IV and anthracene, the yield of IV being so small (about 10 g. from 200 g. I) as to make this method impracticable for the prepn. of IV; 12–5 g. II was obtained and about 40 g. I was recovered unchanged. C. A. R.

2-Amino-4,5-dimethylglyoxaline. RICHARD BURTLES AND F. L. PYMAN. *J. Chem. Soc.* 127, 2012–8 (1925).—2-*p*-Bromobenzenazo-4,5-dimethylglyoxaline, light brown, m. 213–4° (all m. ps. are cor.); it seems to cause irritation of the skin and swelling of the eyelids; HCl salt, orange-yellow, decomp. 135°. Reduction by Sn and HCl gives 69% of 2-amino-4,5-dimethylglyoxaline- HCl , m. 289°; carbonate, with H_2O , m. 114°; picrate, yellow, m. 245°. The amine reacts sluggishly with HNO_2 in dil. or concd. HCl or 25% AcOH , giving no cryst. products, but the solns. give deep colors on treatment with NaOH . It gives deeply colored solns. with $\text{Na}_2\text{Fe}(\text{CN})_6$ and aq. NaOH or with AmNO_2 and EtONa in EtOH . *Ac* deriv., m. 270°; after treating with HCl and NaNO_2 , it gives no color with $\beta\text{-C}_{10}\text{H}_7\text{ONa}$; it instantly decolorizes aq. KMnO_4 . The NH_2 deriv. does not give a benzylidene deriv. 2-*p*-Bromobenzenazo-4(5)-methylglyoxaline (I), yellow, m. 225–6°. 5(4)-*p*-Bromobenzenazo deriv., brown, m. 238°; HCl salt, yellow needles or yellow-red prisms, m. 188°. The yield of these 2 compds. is about 47 and 12%. The constitution of I was established by its reduction by Zn and AcOH to alacreatinine; this is also obtained with SnCl_4 and HCl , together with about 10% of the 2-amino deriv., analyzed as the picrate, brownish yellow, m. 186–7° C. J. WEST

Heterocyclic derivatives of substituted *o*-aminophenols. A. KORCZYNSKI AND ST. OBARSKI. *Bull. soc. chim.* **33**, 1823-32(1923).—All halogenated *o*-aminophenols (I) studied are oxidized by chloranil (II) to the corresponding substituted aminophenoxazone. For characterization of I certain Ac derivs. were prepd., corresponding benzoxazoles were prepd. using AcNH_2 at 220–50°, and mercaptobenzoxazoles with CSCl_2 , and the aminophenoxazones by refluxing with 0.5 mol. II in alc. 4,2-Cl(H_2N) $\text{C}_6\text{H}_3\text{OH}$, prepd. in 70% yield by electrolytic reduction of the NO_2 compd.; Ac deriv., m. 185°; di-Ac deriv., m. 201°; from it were prepd. as above 2-methyl-5-chlorobenzoxazole, m. 63°; 2-mercapto-5-chlorobenzoxazole, m. 275°. 4,2-Br(H_2N) $\text{C}_6\text{H}_3\text{OH}$, similarly prepd., gives 2-methyl-5-bromobenzoxazole, m. 70°; 2-mercapto-5-bromobenzoxazole, m. 283°; and 3-amino-6-bromophenoxazone, m. above 300°, difficultly sol., blue in concd. H_2SO_4 and becoming red on diln. 4,6,2-ClBr(H_2N) $\text{C}_6\text{H}_3\text{OH}$ gives 2-methyl-5-chloro-7-bromobenzoxazole, m. 117°; 2-mercapto-5-chloro-7-bromobenzoxazole, m. 228°; and 2-amino-3-chloro-1,8-dibromophenoxazone, m. above 300°, violet in concd. H_2SO_4 and pptd. on diln. 4,6,2-Br $_2$ (H_2N) $\text{C}_6\text{H}_3\text{OH}$ gives 2-methyl-6,7-dibromobenzoxazole, m. 127°; 2-mercapto-5,7-dibromobenzoxazole, m. 235° (ABSTRACTOR'S NOTE. Apparently an error in numbering of 1 of the 2 foregoing compds.); and 3-amino-1,6,8-tribromophenoxazone, m. above 300°. 4,6,2-I(H_2N) $\text{C}_6\text{H}_3\text{OH}$ gives 3-amino-1,6,8-triodophenoxazone, m. above 300°, blue in concd. H_2SO_4 and showing neither color change nor pptn. on diln.

WM. B. PLUMMER

The simplest *O*-alkyl ethers of benzoylacetone, and methylphenylisoxazole. C. WEYGAND. *Ber* **58B**, 1473-82(1925) — PhCHBrCHBrCOMe and alk. KOH give $\text{PhC}(\text{OEt})\text{:CHCOMe}$ (I), the *b*-ether of BzCl_2Ac (II), i. e. the *O*-ether of the benzoyl-enol form of II (Ruhemann and Watson. *J. Chem. Soc.* **85**, 1180(1904)). Claisen from II with $\text{HC}(\text{OEt})_3$ and FeCl_3 obtained an ether (III) (C. A. **2**, 94) to which he assigned the *a*- or acetyl enol structure, $\text{PhCOCH C}(\text{OEt})\text{Me}$, because, according to him, it gives with NH_2OH an isoxazole (IV), m. 12°, different from the methylphenylisoxazole (V), PhC:CH CMe N O , m. 68°, obtained from II or PhC CCOMe with NH_2OH .

Repetition of C.'s work has shown, however, that the product is really I; with $\text{NH}_2\text{OH} \cdot \text{HCl}$ it always gives chiefly V, and although the mother liquors from V contain lower melting products (about 50°), no substance m. 42° could ever be isolated. I behaves in exactly the same way with $\text{NH}_2\text{OH} \cdot \text{HCl}$. Further to confirm these observations, and furthermore to obtain, if possible, a true *a*-ether, W. prepd. Me ethers of II by 5 methods: (1) from PhCHBrCHBrCOMe and NaOMe ; (2) from PhC CCOMe and MeOH ; (3) from II and CH_2N_2 ; (4) from II and $\text{HC}(\text{OMe})_3$; and (5) from the Na salt of II and Me_2SO_4 . In every case the product was the *b*-ether $\text{PhC}(\text{OMe})\text{:CHCOMe}$ (VI). All these ethers (both Me and Et) are lemon-yellow oils of a faint characteristic odor hydrolyzed to II slowly in the air, almost instantly by mineral acids; only the very first preps. by the C. method were colorless oils which, however, agreed in all their other properties with the remaining preps. and could never again be obtained. If instead of $\text{NH}_2\text{OH} \cdot \text{HCl}$ a neutral or faintly alk. soln. of NH_2OH is used the reaction proceeds differently; from the aq. alc. reaction mixt. can be isolated a very viscous yellowish oil smelling intensely of V and giving with FeCl_3 an unstable emerald-green color (which V alone does not do), but treatment with acids again gives V. After standing for months over CaCl_2 the oil suddenly deposits crystals which, after crystn. from petroleum ether, yield a substance, m. 79–80°, smelling exactly like V, giving no color with FeCl_3 and distg. apparently without decompn.; the distillate completely solidifies after several days and then m. 81–2°, but on again crystg. from MeOH the m. p. suddenly falls to 50° and a homogeneous material can no longer be obtained. After this expt. had been carried out several times it could no longer be successfully repeated, the oil (which, however, always gave the green FeCl_3 reaction) now yielded crystals of V after some weeks. The ether obtained from II and CH_2N_2 gave with O_3 in CCl_4 an ozonide which on decompn. with H_2O yielded BzOMe , further confirming the *b*-structure VI. C.'s IV was finally obtained by treating PhC CCOMe with NH_2OH in faintly alk. soln.; it m. 42°, b. 234° and has the compn. $\text{C}_{10}\text{H}_9\text{ON}$ but whether it has the structure MeC:CH.CPh:N.O cannot be stated with certainty. The yellowish com II

is easily purified by fractionation *in vacuo*; it then b_1 135°, b_2 161°, solidifies 55.5° (thermometer in the liquid, which is undercooled 1–2°), m. 56° on slow, 61° on rapid heating.

C. A. R.

Aminobenzothiazoles. I. 1-Anilinobenzothiazole and its tolyl homologs. R. F. HUNTER. *J. Chem. Soc.* **127**, 2023-8(1925).—1-Anilinobenzothiazole, m. 159° (Ac deriv., m. 158°) gives a tetra-Br deriv., m. 117° (Hugershoff, *Ber.* **36**, 3121, gives 136°)

which, exposed to the air for 2–3 days, loses Br, giving a yellow *tribromide*, sinters 120°, m. 125° to red liquid. 1-*o*-Toluidino-3-methylbenzothiazole, m. 135° (Ac deriv., m. 77°); the *hexabromide*, red, loses Br at 60° and m. 76–8°; the *tribromide*, yellow, turns orange at 205°, red-brown at 240° and m. 250° (decompn.). Either deriv., boiled with EtOH, gives the *HBr salt*, m. 280° (decompn.), of the *di-Br deriv.*, m. 205°. 1-*p*-Toluidino-5-methylbenzothiazole, m. 162° (Ac deriv., m. 158°), gives a *tetrabromide*, sinters 130°, m. 145°, and a *tribromide*, orange, m. 148° (decompn.). Boiling EtOH gives the *HBr salt*, turns yellow 240°, pale brown 240°, and m. 256–8°, of the *di-Br deriv.*, pale cream, m. 159–60°. 1-*m*-Toluidino-*m*-toluthiazole, m. 184–6°; the *hexabromide HBr salt*, red, crumbles to a semi-cryst. mass at 110°, becomes orange and crystals at 187°, pale yellow at 197° but does not m. 200°. Exposure to the atm. gives the *tribromide HBr salt*, yellow, softens 136°, sinters 190°. It is uncertain whether this is the 4- or 6-Me deriv. II. **Naphthylaminonaphthothiazole derivatives.** *Ibid* 2270–4. —Di- α -naphthylthiocarbamide (I) (2 g.) and 2 cc. Br in 20 cc. CHCl₃ give 2- α -naphthylamino- β -naphthothiazole *tetrabromide*, brilliant vermilion, becomes yellow at 200° and colorless at 260°; on exposure to the air, it loses 1 Br, giving the yellow *tribromide*, which becomes colorless at 280°. Using 1 g. I and 1 cc. Br in CHCl₃, there is formed a heptabromide, bright red, which becomes yellow at 160°. These bromides, boiled with EtOH and then treated with warm 2 *N* NaOH, give *dibromo-2- α -naphthylamino- β -naphthothiazole*, sinters 180°, becomes yellow at 240° and m. 270–2°. I (1 g.) and 1 cc. Br in 6 cc. warm CHCl₃ yield a red *tribromide* of II, becomes orange at 180°, yellow at 190°, pale ocher-yellow at 215°, softens at 260° but does not m. 280°. Reduced with H₂SO₃, any of these bromides yields 2- α -naphthylamino- β -naphthothiazole (II), m. 221°; bromination in CHCl₃ gives a *hexabromide*, bright red, showing color changes at 238°; 2- β -Naphthylamino- α -naphthothiazole *hexabromide*, dark red, softens 210°, decomp. 216°; if the soln. is shaken to induce sudden crystn., a purplish red form, m. 196°, results. The *tribromide*, vermilion, m. 245°. 2- β -Naphthylamino- α -naphthothiazole, m. 223°; bromination gives the purple-red *hexabromide*, m. 198°. C. J. WEST

Action of sulfurous acid upon aromatic amino and hydroxyl compounds. XI. Action of phenylhydrazine-bisulfite mixtures upon azo dyestuffs. HANS TH. BUCHERER AND FRITZ STICKEL. *J. prakt. Chem.* 110, 309–53 (1925); cf. *C. A.* 16, 1950.—Orange II heated with NaHSO₃, gives the addn. product 1,2-HOC₁₀H₆N(SO₂Na)NHC₆H₄SO₂Na (I), yellow-orange needles; on continued heating with NaHSO₃ or PhNH₂ and NaHSO₃, there results a good yield of 1,2,4-C₁₀H₃(NH₂)(OH)SO₃H. PhNHNH₂-NaHSO₃ and Orange II give the yellow dye 1,2-PhNHNHC₁₀H₆N(SO₂Na)NHC₆H₄SO₂Na (II), also obtained from I and PhNHNH₂. II is stable towards NaHSO₃ but on heating with alkalis there results a red *hydrazinoazo compd.*, PhNHNHC₁₀H₆N:NC₆H₄SO₂Na (III). Acids decomp. II, yielding *p*-H₂NC₆H₄SO₃H, and a brown product, partly sol. in H₂O. III, with NaNO₂ and excess HCl, gives phenylpseudo-azimidisulfonic acid, C₆H₅N₃-SO₃Na, needles, easily sol. in H₂O but pptd. by acid, and PhN₂Cl. NaNO₂ and excess AcOH give HO₂CC₆H₄N₂X and phenylpseudoazimide. III is oxidized by HNO₃ in the presence of an excess of NaNO₂ to an *o*-disazo dye or *osotetrazone* (IV), light brown needles; this dye is also formed by oxidation by the air in alk. soln., by H₂O₂ and similar oxidizing agents. HCl, even in the cold, yields a violet dye (brown Na salt), which may be a semidine compd., and a small amt. of 8-aminophenonaphthazine, red-brown. Its diazo soln. gives a red dye with R-salt. Heating III with NaHSO₃ gives a yellow addn. product, which resembles but is not identical with II. IV is easily reduced to III; heating with HCl decomp. it, forming principally PhNH₂ and phenylpseudoazimidisulfonic acid. NaNO₂ and excess AcOH or mineral acid, at ordinary temp., give pseudoazimide and its SO₃H acid. NaHSO₃ gives *p*-H₂NC₆H₄SO₃H and an isomeric *pseudoazimide-4-sulfonic acid*. C. J. WEST

Synthesis of datiscetin. JAN KALFF AND ROBERT ROBINSON. *J. Chem. Soc.* 127, 1968–73 (1925).—2-*o*-Methoxybenzylidene-4,6-diacetoxycoumaranone, yellow, m. 174°, results in 55% yields from *o*-MeOC₆H₄CHO, 4,6-dihydroxycoumaranone and Ac₂O. The *dibromide*, m. 163°, gave no trace of a flavonol upon treatment with alkali. With MeOH, HBr is eliminated, giving the compd., C₁₉H₁₂O₆Br(OMe), yellow, m. 192–3°. *o*-Methoxyphloracetophenone, *o*-MeOC₆H₄CO₂Na and (*o*-MeOC₆H₄CO)₂O give 3,2'-dimethoxy-5,7-dihydroxyflavone (datiscetin di-Me ether), m. 218–9°; the yellow concd. H₂SO₄ soln. gradually acquires a weak green fluorescence; alc. FeCl₃ gives a blackish green color; *di-Ac deriv.*, m. 141.5–2.5°. With HI this yields datiscetin, pale yellow, m. 276°, identical with the natural product. The tetra-Ac deriv., m. 141°, the Bz deriv. 191–2°. 3,7,2'-Trimethoxy-5-hydroxyflavone, m. 111–2.5°; FeCl₃ gives a dull brownish green color. 3-Methoxy-5,7-dihydroxy-2-methylchromone, pale yellow, m. 223–4°, results from *o*-methoxyphloracetophenone, (*o*-AcOC₆H₄CO)₂O and *o*-AcOC₆H₄CO₂Na.

$\text{H}_2\text{CO}_2\text{Na}$ or from the ketone, Ac_2O and AcONa . The datiscetin isolated by Schunck and Marchlewski (*Ann.* 277, 266) contains some galangin. C. J. WEST

Synthesis of certain 2-styrylchromonol derivatives. ROBERT ROBINSON AND JUNZO SHINODA. *J. Chem. Soc.* 127, 1973-80(1925).—These products have been prepd. because of the possibility that they may be found in nature. 7-Hydroxy-3-methoxy-2-styrylchromone (I), pale yellow, m. 250° , gives no color with FeCl_3 , a deep yellow soln. with vivid green fluorescence in concd. H_2SO_4 , results in 4.5 g. yield from 4 g. α -methoxyresacetophenone (II), 7.5 g. $\text{PhCH}:\text{CHCO}_2\text{Na}$ and 16 g. $(\text{PhCH}:\text{CHCO})_2\text{O}$. Boiling H_2O gives 3,7-dihydroxy-2-styrylchromone, bright yellow, m. 257° ; the yellow concd. H_2SO_4 soln. has a green fluorescence. $\text{EtOH}-\text{FeCl}_3$ gives a dark brownish green color. The dyeing properties with various mordants are compared with those of 3,7-dihydroxyflavone, which crysts. with H_2O , pale yellow, m. 258° (cf. Kostanecki and Stoppani, *Ber.* 37, 1180(1904)). β -Phenylpropionic anhydride (III), b₄ $216-7^\circ$. Reduction of I by H and Pd or condensation of II and III with $\text{PhCH}_2\text{CH}_2\text{CO}_2\text{Na}$ gives 7-hydroxy-3-methoxy-2- β -phenylethylchromone (IV), m. $186-7^\circ$; the yellow concd. H_2SO_4 soln. has a blue fluorescence. Demethylation of IV gives 3,7-dihydroxy-2- β -phenylethylchromone, m. 169° ; the yellow H_2SO_4 soln. has a blue fluorescence; $\text{EtOH}-\text{FeCl}_3$ gives a dark violet color; it has no mordant dyeing properties. 3-Methoxy-5,7-dihydroxy-2-styrylchromone, yellow, m. 241° ; the orange-yellow EtOH soln. is colored brown by FeCl_3 ; the yellow H_2SO_4 soln. has a green fluorescence. Demethylation gives 3,5,7-trihydroxy-2-styrylchromone, yellow, m. 249° (tri-Ac deriv., m. $215-6^\circ$); its dyeing properties are recorded. 4-Methoxycinnamic anhydride, m. $119-20^\circ$. With II this gives 3,4'-dimethoxy-5,7-dihydroxy-2-styrylchromone, deep yellow, m. 228° ; the orange H_2SO_4 soln. gives a greenish yellow fluorescence; $\text{EtOH}-\text{FeCl}_3$ gives a brown color. The 3,7,4'-tri-HO deriv., bright yellow, m. 156° ; it is quite insol. even in boiling aq. NaOH . The EtOH soln. gives a yellowish brown color with FeCl_3 . 3,4-Dimethoxycinnamic anhydride, m. $174-5^\circ$. With II it yields 3,3',4'-trimethoxy-5,7-dihydroxy-2-styrylchromone, orange, with H_2O , becoming yellow on drying and m. $233-4^\circ$; the orange H_2SO_4 soln. exhibits a weak green fluorescence; the FeCl_3 color is brown; alk. solns. are orange-yellow. 3,7,3',4'-Tetramethoxy deriv., yellow, m. $203-4^\circ$. 3,4'-Dimethoxy-5,7-dihydroxyflavone, pale yellow, m. 234° . FeCl_3 gives a violet color. The yellow H_2SO_4 soln. exhibits a bright bluish green fluorescence. Demethylation gives kaempferol, m. $276-7^\circ$. C. J. WEST

Synthetical experiments in the isoflavone series. I. WILSON BAKER AND ROBERT ROBINSON. *J. Chem. Soc.* 127, 1981-6(1925).—While derivs. of 2-phenylchromone (flavone) are widespread in nature, the occurrence of derivs. of 3-phenylchromone (isoflavone) has not been definitely proved in any single instance, though it has been suggested that prunetin is the Me ether of a trihydroxyisoflavone. The synthesis of this compd. has been undertaken. Isoflavones substituted in position 2 are easy to prep. but the contrary is the case when it is desired to leave this position unsubstituted. 2,4-(HO)₂C₆H₃COCH₂Ph (or its di-Ac deriv.), Ac_2O and AcONa give 90% of the Ac deriv., m. 162° , of 7-hydroxy-2-methylisoflavone, pale brownish yellow, m. 240° ; the aq. NaOH and concd. H_2SO_4 solns. exhibit weak blue and bluish violet fluorescence, resp. Me ether, m. 135.5° . $\text{PhCH}_2\text{COCH}_2\text{CO}_2\text{Et}$ and $m\text{-C}_6\text{H}_4(\text{OH})_2$ with concd. H_2SO_4 give 7-hydroxy-4-benzylcoumarin, faintly brown, m. $225-6^\circ$; the yellow NaOH soln. has a blue, and the colorless H_2SO_4 soln. a bluish violet fluorescence. 5,7-Dihydroxy-2-methylisoflavone, faintly yellowish brown, m. 228° ; di-Ac deriv., m. 169° ; 7-Me ether, m. $186-7^\circ$, and gives a bluish green color with FeCl_3 . 7-Hydroxy-3-phenylflavone (7-hydroxy-2-phenylisoflavone), pale yellow, m. $270-1^\circ$; the pale yellow H_2SO_4 soln. exhibits a bluish green fluorescence. On heating with aq. KOH is obtained a greenish yellow soln. which sets to a clear gel on cooling; a 1% soln. sets to a stiff gel, while even a 0.1% soln. gives a weak gel. Ac deriv., pale yellow, m. $208-9^\circ$. 7-Cinnamylxy-2-styrylisoflavone, pale yellowish brown, m. $213-4^\circ$; the deep yellow H_2SO_4 soln. exhibits green fluorescence. Heated with KOH and then methylated, there results 7-methoxy-2-styrylisoflavone, pale yellow, m. $203-4^\circ$, which is oxidized by KMnO_4 and then heated until CO_2 is no longer evolved, giving 7-methoxyisoflavone, m. 155° ; the H_2SO_4 soln. shows a blue fluorescence. C. J. WEST

Formation of chromones. A criticism. WILSON BAKER. *J. Chem. Soc.* 127, 2349-58(1925); cf. preceding abstr.—B. and R. state that the products described by Jacobson and Ghosh (*C. A.* 9, 2222, 2762; 10, 1031) as γ -benzopyrones or chromones are really the isomeric α -pyrones or coumarins; of the 24 fundamental compds. concerned, 13 of the true chromones have been prepd. The only safe criterion of the production of a chromone and not the coumarin is the formation on hydrolysis of a HO ketone. The correct names of the compds. prepd. by J. and G. are given with their properties. Ben-

zylresacetophenone, Bz_2O and $BzONa$ at $170-80^\circ$ for 6 hrs. give 7-hydroxy-3-benzyl-2-phenylbenzo- γ -pyrone, m. $272-4^\circ$; the aq. $NaOH$ soln. shows a slight bluish green fluorescence; Bz deriv., m. 167° ; Ac deriv., m. 150° ; in concd. H_2SO_4 they show a weak blue fluorescence. $PhCH_2CH_2CN$ and $1,3,5-C_6H_3(OH)_3$ in Et_2O , satd. with HCl , give benzylphloracetophenone, crystg. with $1H_2O$, m. $139-40^\circ$. With Ac_2O and $AcONa$ this gives 5,7-dihydroxy-3-benzyl-2-methylbenzo- γ -pyrone, m. $200-1^\circ$, the intermediate *di-Ac* deriv., m. 112° ; the concd. H_2SCl solns. show a weak blue-green fluorescence. With Bz_2O and $BzONa$ there results the 2-*Ph* deriv., pale yellow, m. $202-3^\circ$; *di-Ac* deriv., pale yellow, m. 126° . The pale yellow solns. in concd. H_2SO_4 show a weak blue-green fluorescence. Benzyloracetophenone, m. 118.5° , from β - $PhCH_2CH_2CN$. With Ac_2O there results 7-hydroxy-3-benzyl-2,5-dimethylbenzo- γ -pyrone, m. $294-5^\circ$, through the intermediate *Ac* deriv., m. $138-9^\circ$; Me_2SO_4 gives a *Me* deriv., m. 109° . These compds. in concd. H_2SO_4 show a blue fluorescence. 7,8-Dihydroxy-3-phenyl-2-methylbenzo- γ -pyrone, m. $219-20^\circ$; *Ac* deriv., m. 111.5° . The corresponding 2,3-*di-Ph* deriv., m. 297° ; its *di-Ac* deriv., m. $177-8^\circ$. 7,8-Dihydroxy-3-benzyl-2-methylbenzo- γ -pyrone, m. $203-5^\circ$; *di-Ac* deriv., m. 126° . 7,8-Dihydroxy-3-benzyl-2-phenylbenzo- γ -pyrone, pale yellow, m. $275-6^\circ$; *di-Ac* deriv., m. $175-6^\circ$. C. J. WEST

Experiments in the chromone and 1-thiochromone series. F. ARNDT WITH W. FLEMMING, E. SCHOLZ, V. LÖWENSOHN, G. KALLNER, B. MISTERT. *Ber.* **58B**, 1612-32 (1925); cf. C. A. **18**, 2167.—Br substitution in the thiochromanones (I) occurs stepwise, so that any degree of substitution can be effected at will by varying the amt. of Br, but further substitution of an already brominated deriv. is much more difficult than the introduction in 1 operation of the same total amt. of Br into the unsubstituted I. The 1st Br atom always enters position 3 and the resulting mono-Br derivs. all show the typical burning action on the skin characteristic of α -haloketones. 6-Methylthiochromanone (II) gives only a 3-*Br* (III) and a 3,3-*Br_2* deriv. (IV); IV is S-yellow and considerably more difficultly sol. than II or III. Thiochromanone (V), on the other hand, yields colorless 3-*Br* (VI) and 3,3-*Br_2* derivs. (VII), not materially different from each other, and an intensely yellow and difficultly sol. 3,3,6-*Br_3* deriv. (VIII). 6-Bromothiochromanone (IX) (prepd. from p - BrC_6H_4SH) forms a 3,6-*Br_2* deriv. (X) and, on further bromination, VIII. Color and difficult soly. therefore appear in the 3,3-*Br_2* compds. only when position 6 is also occupied by Me or Br. Similar relationships are found in the thioflavanones (XI); these, if the 3- and 6-positions are all occupied, can also still add 4 Br atoms (on the S). Dil. alc. alkalies or, better, C_6H_5N , easily eliminate HBr from the 3-*Br* derivs. of I and XI, with formation of the corresponding thiochromones (XII) and thioflavones (XIII); the XII and XIII not brominated in the pyrone ring can also be obtained directly from the corresponding I and XI with PCl_5 (Löwenbein, C. A. **19**, 288). The Br in the brominated XII and XIII is held very firmly. The action of Br on the XII and XIII does not result in substitution but in addn. of Br at the double bond; the resulting dibromides of the XIII are brown-red while those of the XII show a peculiar yellow-red color dimorphism and are very difficultly sol. in HO -free mediums. Chromone (XIV) itself with Br gives, insofar as it does not form the yellow bischromone hydrotribromide (XV), a colorless dibromide (XVI) (undoubtedly 2,3-dibromochromanone) easily sol. in HO -free solvents; whether the dibromides of the XII are analogous 2,3-*Br_2* derivs. of the I is left an open question for the present. With alc., etc. the dibromides of the XII give 3-*Br* derivs. of the XII, identical with those obtained from the 3,3-*Br_2* derivs. of the I. The dibromides of the XIII with alc., etc. regenerate the XIII, their 3-*Br* derivs. being formed only when an excess of Br is present at the same time. The 3-*Br* deriv. (XVII) of 6-methylthioflavone (XVIII) thus obtained from the dibromide (XIX) is a labile form of that obtained from the 3,3-*Br_2* deriv. (XX) of 6-methylthioflavanone (XXI) and changes into its stable isomer (XXII) only after seeding. The same isomerism is found in the sulfone of XVII but in this case it is the compd. obtained from the flavanone which is the labile form. The S of the I and XI is easily oxidized by H_2O_2 - $AcOH$ even in the cold. Little H_2O_2 , acting a short time, gives a mixt. of sulfoxides and sulfones; the sulfoxides cannot be obtained alone with the calcd. amt. of H_2O_2 nor has it been possible to effect their sepn. from the sulfones. Their presence can be detected by the intense red-violet color which they give with hot dil. (best alc.) alkali; this color soon disappears, the end result of the reaction being the elimination of H_2O and the formation of the corresponding XII or XIII. On longer action in the cold or shorter action in hot soln., H_2O_2 gives sulfones exclusively (except with the 3-*Br* derivs. of the I, where the oxidation stops at the sulfoxide stage). With alkalies, these undergo deep-seated decompn. without color changes; the sulfones of the XI yield BzH (but in far smaller amt. than that corresponding to the Ph present originally), and in all cases the alk. soln. contains an amorphous, strongly acid, S-contg.,

non-homogeneous substance (apparently a mixt. of SO_3H or SO_2H acids). In concd. H_2SO_4 the sulfones dissolve entirely without color. Oxidation of the **XII** and **XIII** is much more difficult, the **XIII** not being attacked at all in the cold and the **XII** only very slowly. The sulfones of the **XII** and of **XVIII** are colorless, that of thioflavone (**XXIII**) is light yellow. Towards alkalis they are much more stable than those of the **I** and **XI**. The sulfones of the **XII** dissolve in concd. H_2SO_4 with yellow, those of the **XIII** with strong orange-red color. Those of the **XII** add Br at the double bond rapidly, those of the **XIII** more slowly. The dibromide (**XXIV**) of 6-methylthiochromonesulfone (**XXV**) with boiling alc. loses HBr and forms a 3-Br deriv. (**XXVI**) of **XXV**. Bromination of 6-methylthiochromonesulfone (**XXVII**) gives a 3-Br deriv. (**XXVIII**) which with $\text{C}_6\text{H}_5\text{N}$ yields **XXV**, and condensation of the **XXVII** with BzH gives the same (colorless) 3-benzal deriv. (**XXIX**) as is obtained by oxidation of the (intensely yellow) 3-benzal deriv. (**XXX**) of **II**. Furthermore, bromination of 6-methylthioflavanonesulfone (**XXXI**) gives a 3-Br deriv. (**XXXII**) which with alkalis splits off BzH. Further bromination of **XXXII** gives a 3,3-Br₂ deriv. (**XXXIII**). **XXVI** is also obtained by oxidation of 3-bromo-6-methylthiochromone (**XXXIV**), which is prepd. from **IV** with $\text{C}_6\text{H}_5\text{N}$. **III**, from **II** and 2 atoms Br in AcOH, m. $60-1^\circ$, sol. in concd. H_2SO_4 with deep violet-red color; **IV**, obtained with 4 or more atoms Br, m. 155° (decompn.), sol. in H_2SO_4 with violet color. **VI**, from **V** and 2 atoms Br in CHCl_3 , m. 76° ; **VII**, obtained with 4 atoms Br, m. 97° , sol. in concd. H_2SO_4 with violet color. β -[*p*-Bromophenylmercapto]propionic acid, from *p*-Br $\text{C}_6\text{H}_4\text{SH}$ and $\text{ClCH}_2\text{CO}_2\text{H}$, m. 119° , converted by concd. H_2SO_4 into **IX**, m. 70° , sol. in H_2SO_4 with crimson color, gives with 2 atoms Br in CHCl_3 **X**, m. $109-10^\circ$, sol. in H_2SO_4 with crimson-violet color. **VIII**, m. 171° , insol. in H_2SO_4 . 3-Bromo-6-methylthioflavanone, m. 120° , sol. in H_2SO_4 with deep red color and violet dichroism; 3,3-Br₂ deriv. (**XX**), yellow, m. 138° , sol. in H_2SO_4 with violet color. 3-Bromothioflavanone, m. 135° ; 3,3-Br₂ deriv., oily; 3,3,6-Br₃ deriv., yellow, m. 157° (decompn.). 2-Bromothiochromonol, from thiochromonol and 2 or more atoms Br in AcOH, light yellow, m. 195° , forms an intensely yellow, difficultly sol., stable Na salt with dil. NaOH. 2-Bromo-6-methylthiochromonol, light yellow, m. 179° ; 2-Cl analog, from 6-methylthiochromonol (**XXXV**) in CHCl_3 with Cl in CCl_4 , brownish yellow, m. $175-6^\circ$; 2,2-Cl₂ deriv., from **XXXV** in CHCl_3 treated with Cl until the evolution of HCl ceases or from **XXXV** and SOCl_2 on the H_2O bath, yellow, m. $138-9^\circ$. 3-Benzalthiochromanone, from **V** in BzH satd. with HCl, faintly yellow, m. $105-6^\circ$, sol. in H_2SO_4 with dark brown-red color and only faint green dichroism. 6-Methyl-1-thiochromone, from **III** and boiling $\text{C}_6\text{H}_5\text{N}$ or NaOH in hot alc. or (in 70% yield) from **II** with PCl_5 in boiling C_6H_6 , m. $61-2^\circ$, easily becomes pink or light brownish, sol. in H_2SO_4 without color but with strong blue fluorescence; 3-Br deriv. (**XXXIV**), m. $117-8^\circ$. 1-Thiochromone, m. 78° ; 3-Br deriv., m. $142-3^\circ$; 6-Br deriv., m. 157° ; 3,6-Br₂ deriv., m. 178° . **XXII**, m. $117-8^\circ$. 3-Bromo-1-thioflavone, m. 136° ; 3,6-Br₂ deriv., m. $195-6^\circ$. **XIV**, m. 59° , which has hitherto been difficultly accessible, is obtained in 50% yield from chromanone with PCl_5 in boiling C_6H_6 . 6-Methylthiochromone dibromide, brown-red cryst. ppt. becoming yellow on standing; from AcOH the red ppt. generally seps. first in a yellow form which then changes to the red and back again to the yellow form which m. sharply $142-3^\circ$ to a red liquid and forms a red-yellow soln. in AcOH; the red form (from AcOH contg. an excess of Br) sinters 120° , m. 142° , changes into the yellow form on cautious heating. 3-Br deriv., unstable red crystals. 1-Thiochromone dibromide, seps. first as the yellow form, m. 141° ; the red form m. $130-5^\circ$. **XIX**, m. $121-3^\circ$ (decompn.). **XVII**, m. $98-9^\circ$. 1-Thioflavone dibromide, m. $111-2^\circ$; 3-bromo-6-methyl deriv. (**XXXVI**), m. $97-9^\circ$, from **XVII** or **XXII**, regenerates **XXII** on standing in the air or heating with alc. 3,3-Dibromo-6-methylthioflavanone tetrabromide, from **XX** in CS_2 with 4 or more atoms of Br, orange yellow, begins to sinter 120° , m. $127-9^\circ$, decomps. $137-40^\circ$; in the air or more quickly in hot C_6H_6 it loses HBr and Br with formation first of **XXXVI** and then of **XXII**. Bromination of **XIV** in concd. CS_2 soln. gives **XVI** almost exclusively, in more dil. CS_2 soln. or in CHCl_3 considerable **XV** also, in AcOH almost only **XV**. **XVI**, m. $104-5^\circ$ to a red liquid, converted by boiling its solns. (e. g. in alc.) into 3-bromochromone, m. $65-6^\circ$. **XV**, $(\text{C}_6\text{H}_5\text{O}_2)_2$. HBr Br₂, m. 127° to a red liquid, easily sol. in cold alc. with yellow color, decompd. by heating above its m. p. or with solvents. β -[*p*-Tolylsulfonyl]propionic acid, from $\text{MeC}_6\text{H}_4\text{SCH}_2\text{CH}_2\text{CO}_2\text{H}$ and 1 mol. H_2O_2 in cold AcOH, m. $147-8^\circ$; its H_2SO_4 soln. becomes red to blue-violet on heating. In boiling AcOH is obtained the sulfonyl compd., m. $112-3^\circ$, sol. without color in concd. H_2SO_4 . [*p*-Tolylsulfonyl]hydrocinamic acid, m. $200-1^\circ$, unchanged by hot POCl_3 or H_2SO_4 . 6-Methylthiochromanonesulfoxide, could not be sepd. from the sulfone (**XXVII**) which, obtained almost quant. by long action of H_2O_2 in cold AcOH or short boiling, m. 163° and dissolves in H_2SO_4 with no or only faintly yellowish color. Thiochromanonesulfone, m. $131-2^\circ$, sol. in H_2SO_4 without

color. 6-Methylthioflavanonesulfoxide (contg. some of the sulfone (XXXI)), m. 177–8° to a red liquid. XXXI, m. 177–8° (only partially on slow heating, then resolidifying and finally m. 191–2°), sol. in H_2SO_4 without color, slowly sol. in cold alc. alkalies with faint yellow color and reprecipitated by acids, insol. in cold aq. alkalies and decomposed on heating. XXVIII, m. 165°; sulfoxide, from III and $\text{H}_2\text{O}_2\text{-AcOH}$, m. 158°. 3-Bromothiochromanonesulfone, m. 199–200°. XXXIII, m. 198°, sol. in H_2SO_4 without color; sulfoxide, from IV and $\text{H}_2\text{O}_2\text{-AcOH}$, m. 166°. XXXII, decomps. 238–9°, difficultly sol. in H_2SO_4 with faint yellowish color; 3,3- Br_2 deriv., decomps. 232–9°. 3-Bromothioflavanonesulfone (given as chromanone in the original.—ABSTR.), m. 175–6° to a red liquid. XXIX, colorless to faintly yellowish, m. 204–5°, sol. in H_2SO_4 with light orange color. XXV, m. 146°, sol. in H_2SO_4 with greenish yellow color. Thiochromanonesulfone, m. 144°, sol. in H_2SO_4 with yellow color. XXIV, m. 192° (decomps.), sol. in H_2SO_4 without color. XXVI, from XXIV and $\text{C}_6\text{H}_5\text{N}$, XXXIII and boiling alc. or XXXIV and $\text{H}_2\text{O}_2\text{-AcOH}$, m. 216–7°. 6-Methylthioflavanonesulfone (XXXVII), m. 156–7°, quite stable towards boiling alkalies. Thioflavanonesulfone, light yellow, m. 132–3°. Dibromide of XXXVII, faintly yellowish, m. 221°. 3-Br deriv. of XXXVII, from the 3,3- Br_2 deriv. of XXXI with boiling $\text{C}_6\text{H}_5\text{N}$, faintly yellowish, m. 175–6° on rapid heating; on slow heating it sinters and changes, after repeated melting and resolidification (180–95°) into a stable form, m. 206–7°, which is obtained directly by oxidation of XVII or XXII. O-Me ether of XXXV, obtained with Me_2SO_4 , m. 108–9°, insol. in alkalies. Benzoate of XXXV, m. 181°. The 2,2- Cl_2 deriv. of XXXV is decomposed by boiling H_2O into 5-methylthiouraphthenequinone, m. 145°, and 3-methyl-6-mercaptobenzoic acid, m. 221°, easily sol. in Na_2CO_3 with yellowish color; S-Me ether of the acid, m. 134°. C. A. R.

Pyrone problem. 1-Thiopyranes and 1-thiopyranones. F. ARNDT, P. NACHTWEY AND J. PUSCH. *Ber.* 58B, 1633–44 (1925); cf. preceding abstr.—The term *pyranones* is suggested, in analogy with chromanones, for tetrahydropyrans. Thiopyranones (I) can be obtained by simple addn. of H_2S to α,α' -diolefinketones in very faintly alk. soln. Under such conditions $\text{CO}(\text{CH}:\text{CHPh})_2$ (II) smoothly yields the colorless 2,6-diphenylthiopyranone (III), also obtained from $\text{CO}(\text{CHBrCHBrPh})_2$ (IV) with alc. Na_2S or NaSH . III seps. sometimes in rhombic, sometimes in lower melting triclinic crystals of the same compn. and mol. wt. The former are formed predominantly in solns. of lower, the latter in solns. of higher alkalinity. The difference in m. p. persists in all derivs. which still contain the hydrogenated ring but disappears as soon as the ring is ruptured or dehydrogenated. Thus the 2 sulfoxides or sulfones of III give III with dil. alkalies; dehydrogenation of the two III yields the same 2,6-diphenyl-1-thiopyrone (V); the two 3,5-Br₂ sulfones form, on elimination of HBr, the same diphenylthiopyranonesulfone (VI). There can be no doubt, therefore, that the 2 isomeric series differ from each other in the *cis*- or *trans*-position of the Ph groups to the plane of the ring. A direct conversion of the 1 stereoisomeric series into the other was never observed. The ring system in the I is quite stable towards alkalies and acids but sensitive to oxidizing agents. The I show a distinct tendency to condense with BzH and $p\text{-ONC}_6\text{H}_4\text{NMe}_2$ but form amorphous products of high mol. wt.; in general, loading of the 3- and 5-positions so increases the unsaturation of the whole system that it becomes "resiniferous." $\text{H}_2\text{O}_2\text{-AcOH}$ in the cold gives directly the sulfones, which sep. first as H_2O_2 addn. products. Oxidation in hot soln. ruptures the ring. The sulfoxides are obtained with Br in Et_2O in the presence of H_2O or in $\text{AcOH-C}_6\text{H}_5\text{N}$ and are converted into the sulfones by H_2O_2 . The sulfoxides and sulfones are very sensitive to alkalies, smoothly giving II while the S is changed partially into sulfide and partially into sulfite or sulfate. The action of Br on the I is difficult to control; HBr is always evolved, to be sure, indicating substitution in positions 3 and 5, but the above mentioned tendency to resinification when these positions are loaded manifests itself, and moreover the Br simultaneously attacks the ring S and ruptures the ring. With more than 4 atoms of Br, IV and S₂Br₂ are smoothly formed; with 4 atoms, IV is also often obtained in part; otherwise amorphous masses of high mol. wt. are formed. In 3 of many trials, with the high melting form of III and in 1 with its isomer there was obtained a small amt. of a hydrotribromide-like substance sepg. from alc. in yellow, halogen-free needles, which with Br at first instantly add it but then evolve HBr; the yellow substance is believed to be 2,6-diphenyldihydro-1-thiopyrone (VII); "mild" bromination methods have no definite products. The sulfones of III, on the other hand, are smoothly converted into V with 4 mols. PCl_5 in C_6H_6 , but at the same time is formed a 3-Cl deriv. (VIII) of V (sometimes VIII is the chief product). The colorless V with Br in CHCl_3 , AcOH or CS_2 gives a red dibromide (IX) which can be crystd. from abs. alc. but with hot aq. alc. regenerates V. V does not react with NH_4OH . CH_3Ac , with P_2S_5 in boiling C_6H_6 gives 40% of triiodiacetylacetone

cyclodisulfide (?), S. CMe:CH. CS. CH: CMe. S, orange m. 183-4°, mol. wt. in camphor

176 80 **III**: A-form, m. 113-4°, mol. wt. in camphor 268-74; B-form, m. 87-8°, mol. wt. in camphor 264-8. Both immediately become intensely crimson in contact with concd H_2SO_4 and slowly dissolve with intense dark red color. *Phenylhydrazones*: A, m. turbid 155-6°, decomp. 190°; B, m. 142-5° (decompn.). *Semicarbazones*: A, m. 206-7° (decompn.); B, crystals with difficulty. *Sulfones*: A, m. 235°, seps. first as the H_2O_2 addn. product, m. 134-5° (decompn.); B, m. 196° (H_2O_2 compd., m. 123°). *Sulfoxides*: A, m. 196-8°, mol. wt. in camphor 283 1-6.7, sol. in H_2SO_4 with light orange color; B, m. 136-7°. *3,5-Br₂ sulfones*: A, m. 247°; B, m. 231-5°. **V**, m. 132-3°, sol. in H_2SO_4 with faint yellowish color and faint greenish fluorescence (yield, 15-25%); *HCl salt* **VIII**, m. 119 20°; *HCl salt* **IX**, m. 171°, sol. in alc. with light yellow color. **VI**, also obtained from **V** with $AcOH-H_2O_2$, yellow, m. 141-5°, sol. in H_2SO_4 with red-violet color. *2,6-Diphenyl-3-chloro-1-thiopyrone-sulfone*, from **VIII** with H_2O_2 - $AcOH$ or from **VI** in $CHCl_3$ or CCl_4 , light yellow, m. 163°, sol. in H_2SO_4 with intense red color. The results of Hellthaler on the action of Cl on **II** (C. A. 9, 56) could not be reproduced; no tetrachloride was obtained but only a dichloride, m. 128-9°, sol. in H_2SO_4 with light orange-red color and converted by boiling alc. KOAc into the light yellow PhCH₂-CHCOCl CHPh, m. 78-9°. *Oxime* of **VI**, light yellow, begins to decomp. 165°, m. 186-7°; of **VIII**, faintly yellowish, begins to decomp. 180°, m. 211°. **VII**, m. 142°, sol. in H_2SO_4 with orange-red color. Condensation of $CO(CH_2CO_2H)_2$ with BzH and HCl and pptn. of the product from Na_2CO_3 with acids gave not only Petrenko-Kritschenko's 2,6-diphenylpyranone, needles, m. 130° (*J. prakt. Chem.* 60, 150(1899)), but also in 1 expt a stereoisomeric form, plates, m. 174-5°, both smoothly give **II** with dil. alc. HCl. *2,6-Diphenylpyrone dibromide*, from the pyrone and less than 2 atoms Br in $CHCl_3$ or from the yellow tetrabromide (which is obtained with more than 2 atoms Br) gently warmed under its mother liquor, brown-red, m. 165-6°, slowly dissolves in boiling abs. alc., the orange bispyrone hydrotribromide, m. 174-5°, sepg. on cooling. C. A. R.

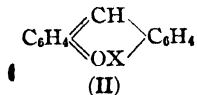

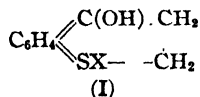

Conversion of 4-thiopyrones into dipyrlylenes. Dithiopyrylenes. F. ARNDT, P. NACHTWEY AND J. PUSCH. *Ber.* 58B, 1644-6(1925), cf. Schonberg, C. A. 19, 1424. *Dithioflavone* (**I**), like xanthione, is not altered by heating alone, but neither can any definite product be obtained with Cu. The "dipyrlylene reaction," if it occurs at all, seems to give definite products only when the original substance is sym. with respect to the C:S group. Thus, while 2,6-diphenyl- (**II**) and 2,6-diphenyl-3-chlorodithiopyrone (**III**) both undergo spontaneous transformation on heating, only **II** gives a well-defined product which can be isolated, viz., tetraphenyldithiopyrylene (**IV**). **I**, from 1-thioflavone and 2 parts P_2S_5 in boiling C_6H_6 , dark brown, m. 112-3°, sol. in alc. with brown, in C_6H_6 and Et_2O with deep green color. **II**, from diphenyl-1-thiopyrone (**V**) (preceding abstr.) as already described for 4-thiodiphenylpyrone (C. A. 19, 515), dark brown leaflets with strong green dichroism, m. 129 30°, sol. in alc. with brown color, in C_6H_6 (concd. soln.) with red color by transmitted light and green color by incident light; the dil. soln. in C_6H_6 is green and the soln. in concd. H_2SO_4 yellow-red with green fluorescence. **III**, brown-red needles with bluish luster, m. 155°, sol. in C_6H_6 with red-green dichroism, when it is heated at 165-70°, the melt soon becomes deep brown-red but does not solidify and the deep brown-red solns. in hot C_6H_6 or $C_6H_4Me_2$ yield no crystals on cooling. **II**, boiled a long time in alc. with aq. $NH_2OH \cdot HCl$ and Na_2CO_3 gives H_2S and 83% of diphenyl-1-thiopyrone oxime, $C_{17}H_{13}ONS$, light brown-yellow, m. 197-8°, sol. in H_2SO_4 with light lemon-yellow color; **V** similarly treated is recovered unchanged. **IV**, from **II** heated at 145° (only 1 min. elapses between the melting and resolidification), dark brown-red, almost black needles with strong green surface luster, m. 312-3°. C. A. R.

Question of the existence of indigoid dyes with a hydrogenated six-ring. F. ARNDT AND J. PUSCH. *Ber.* 58B, 1646-7(1925) - Herzog and Kreidl (C. A. 17, 1463) obtained from α -tetralone with α -isatin anil and α -thionaphthenequinone anil (**I**) indigoid dyes which they considered to be 2-dihydronaphthalene-2'-indole-indigo and -2'-thionaphthene-indigo, resp., formed by simple condensation. Later Friedländer and Sander concluded, from the absorption of the former dye, that it is really 2-naphthalene-2'-indole-indigo, i. e., that dehydrogenation accompanies the condensation. To throw possible light on the question, A. and P. tested the ability to condense of thiochromanones, which are analogous to the tetralones in many respects but in which a dehydrogenation corresponding to the above cannot come into play; the results of their expts indicate in their totality that the question at the head of their paper is to be answered in the negative. Alk. 6-methylthiochromonol (**II**) does not react at all with

cold $K_2Fe(CN)_6$ but on boiling slowly deposits dark red flocks of 5,5'-dimethylthioindigo and the filtrate evolves CO_2 in abundance on acidification. Mol. amts. of II or 6-methylthiochromanone (III) and I in boiling Ac_2O deposit no dye, the soln. merely gradually becoming a dirty dark brown. Mol. amts. of III and 2,2-dibromohydroxythionaphthene (V) in boiling $AcOH$ evolve HBr and soon deposit ordinary thioindigo (also obtained from 6-bromothiochromanone and V); i. e., the III is not a component of the dye. II and V likewise evolve HBr and yield thioindigo almost quant., but, on cooling, the soln. further deposits 3-bromo-6-methylthiochromonol (cf. 3rd abstr. preceding); i. e., the II and V mutually interchange a H for a Br atom and the resulting bromohydroxythionaphthene, by spontaneous loss of HBr , gives thioindigo. The reverse interchange occurs when the 2,2- Cl_2 deriv. of II is boiled in $AcOH$ with hydroxythionaphthene; HCl , thioindigo and the 2- Cl deriv. of II are formed. A. and P. believe that the dyes obtained by H. and K. are not derived from α tetralone but from α -naphthol.

Halochromism of hydrogenated pyrone and thiopyrone systems. F. ARNDT AND J. PUSCH. *Ber.* 58B, 1648-54 (1925); cf. preceding abstrs.—All 1-thiobenzopyrone derivs. contg. the hydrogenated hetero-ring (thiochromanones, thioflavanones and their substitution products) dissolve in concd. H_2SO_4 with intense color while their sulfones dissolve without color. In the dehydrogenated systems (thiochromones and thioflavones), on the other hand, it is the sulfones which form colored solns. That these color reactions of the hydrogenated compds. are really due to halochromism has now been shown definitely, for the thiochromanones, by the isolation of definite colored salts regenerating the org. component unchanged on hydrolysis. These salts are undoubtedly sulfonium salts to which might be assigned a structure (I) corresponding to that (II) given by Werner to the salts of xanthidrol and thioxanthidrol. If the chromophore resides in the *o*-quinonoid C_6H_4 ring, completely hydrogenated pyrone and thiopyrone rings not condensed with a C_6H_4 ring should not show halochromism, but as a matter of fact 2,6-diphenylthiopyranone (III) dissolves in H_2SO_4 with deep red color and di-Me 2,6-diphenylthiopyranone 3,5-dicarboxylate (IV) with strong yellow color. In these non-condensed systems, however, it has not been possible to obtain the decisive proof that they are the org. components of colored salts; in fact, their behavior, especially that of 2-phenyl-6,6-dimethylthiopyranone (V), is more in harmony with the view that these systems as such form colorless, unstable salts and that the color is due to the halochromism of a transformation product which is formed to a very small extent from the original substance by the action of the acid and is contained also in the decolorized product of hydrolysis. What the nature of this transformation is it has not yet been possible to establish. Since it can by no manner of means effect a ring condensation, the chromophore in the benzo series cannot be sought for in the C_6H_4 ring. A. and P. believe that in all these color reactions the hetero-ring atom itself plays a much greater role in the light absorption than has hitherto been ascribed to it. The chroman- and thiochroman-4-ols obtained by the action of $MeMgI$ on chromanones, thiochromanones and thioflavanones dissolve in H_2SO_4 at first with a blue color which, however, is quickly replaced by a dirty brown, probably as the result of a change into the chromenes. 6-Methylthiochromanone (VI) heated with 70% $HClO_4$ until it has dissolved clear with intense red color yields on cooling the perchlorate, VI. $HClO_4$, orange-red leaves, stable in the air for some time, longer if protected from moisture, deflagrates violently on heating, decolorized and converted into VI by shaking with H_2O . Thiochromanone dissolves in $HClO_4$ even in the cold with red color but the salt is very sol. and could not be obtained in cryst. form. Chromanone dissolves with a dark yellow color. The yellow soln. of VI in dry C_6H_6 satd. with HCl , treated in the absence of moisture with $SnCl_4$ in C_6H_6 , becomes intensely red and soon deposits deep red crystals, 2VI. H_2SnCl_6 , rapidly decompd. by moisture, and even in dry air losing HCl and changing into the yellow cryst. compd. 2VI. $SnCl_4$, which is also obtained from VI and $SnCl_2$ in C_6H_6 and yields the preceding red compd. on treatment with HCl in C_6H_6 . Chromanone likewise forms a faintly yellowish compd. ($C_6H_5O_3$), $SnCl_4$ and a dark yellow hexachlorostannate, which, however, changes very easily into the $SnCl_4$ compd. With Me_2SO VI does not yield a H_2O -sol. addn. compd. but the mixt. dissolves in H_2SO_4 with considerably fainter color than the VI alone. III does not dissolve in cold 70% $HClO_4$ and on warming decomp. into a brown oil; on shaking in cold $CHCl_3$ with the $HClO_4$, however, it yields crystals which are at first colorless and, after drying *in vacuo*, contain 20-30% $HClO_4$. If the III is shaken in C_6H_6 at about 60° with the $HClO_4$, the C_6H_6 layer quickly becomes deep violet and on cooling deposits deep violet crystals stable in a dry atm. but decolorized and dissolved by hot alc., H_2O pptg. III. V, obtained in 80% yield from benzalmesityl oxide, $NaOAc$ and H_2S in 90% alc., m. 42°, b_p 175-6°, dissolves

in cold concd. H_2SO_4 at first almost without color, but within 1–2 min. the soln. becomes crimson and with H_2O gives a yellow oil. *4-Methyl-4-chromanol*, m. 107° . *4,6-Dimethyl-4-thioflavanol*, m. $115-6^\circ$, gives with hot HClO_4 yellow crystals.

C. A. R.

Thiochromanones and transformation products. II. F. KROLLPFEIFFER, WITH H. SCHULTZE, E. SCHLUMBOHM AND E. SOMMERMEYER. *Ber.* **58B**, 1654–76 (1925); cf. C. A. **18**, 230 and preceding abstrs.—A report on the development of methods for detg. the constitution of the thiochromanones obtained from $\text{RSCH}_2\text{CH}_2\text{CO}_2\text{H}$ ($\text{R} = \text{aryl}$) and concd. H_2SO_4 . β -[Arylmercapto]propionic acids: *p*-Chlorophenyl (58 g. from 45 g. *p*- $\text{ClC}_6\text{H}_4\text{SH}$), m. $90-1^\circ$; *p*-methoxyphenyl, m. $81-2^\circ$; 1-tetralyl, m. 95° . β -[Arylmercapto]butyric acids: *Ph*, thick oil, b_{10} 185° (yield, about 60%); *p*-tolyl, b_{10} 193° , m. $44-5^\circ$ (yield, about 75%). Thiochromanones: 6-*Cl*, m. $67-9^\circ$ (yield, quant.); 6-*MeO*, obtained in 40% yield from $\text{MeOC}_6\text{H}_4\text{SCH}_2\text{CH}_2\text{CO}_2\text{H}$ with H_2SO_4 and in 65% yield by distn. of the acid *in vacuo* over P_2O_5 (POCl_3 gave the thiochromone), b_{12} $185-6^\circ$, m. $29-30^\circ$ (semicarbazone, m. 212° (decompn.) on slow heating, 221° when plunged into a bath at 205° and then rapidly heated); 7,8-tetrahydrobenzo, m. $60-1^\circ$, sol. in H_2SO_4 with pure red color, (semicarbazone, m. 232°); tetrahydrobenzo, from β -[tetralyl-2-mercapto]propionic acid, m. $60-1^\circ$ (semicarbazone, m. 255° ; the semicarbazone m. 224° described in the earlier paper proved to be a mixt. of the above, m. 255° , and an isomer, m. $238-40^\circ$, which when decompd. gave an almost colorless, very viscous oil, b_{14} 223°). 2-*Me* (yield, about 60%), viscous oil, b_{13} 152° , m. $18-9^\circ$ (semicarbazone, m. $167-8^\circ$); 2,6-*Me_2* (yield, about 65%), b_{20} 179° , m. $64-5^\circ$ (semicarbazone, m. $205-6^\circ$). 6-Methylthiochromanone perbromide, $\text{MeC}_6\text{H}_4\text{COCH}_2\text{CH}_2\text{SBr}_2$, from

6-methylthiochromanone (I) and 1 mol. Br_2 in cold CS_2 , CHCl_3 or AcOH , dark red crystals similar to red P, quickly loses HBr in the air or in a desiccator with formation of the 3-*Br* deriv. (II) of I, regenerates I with boiling PhNI_2 , gives with cold NaOEt an orange product sol. in alc. aq. NaOH with KMnO_4 -like color, the soln. dyeing cotton a violet-red which changes to yellow on moistening with AcOH . Sulfoxide of I, from the perbromide shaken with H_2O , m. 110° (yield, 3 g. from 5 g. I), also obtained from I and H_2O_2 - AcOH , gives II when evapd. with HBr , regenerates I with $\text{Zn-H}_2\text{SO}_4$ and gives with cold NaOEt 2 compds. m. 195° and 243° , resp. 2,6-Dimethylthiochromanone sulfoxide (from the scarlet perbromide with H_2O), m. $97-8^\circ$; yield, 60%. The following 3-bromothiochromanones, obtained with the calcd. amt. of Br in CS_2 , are faintly yellow, produce violent burning on the skin and dissolve in H_2SO_4 with violet-red color: *unsubstituted*, m. $76-7^\circ$; 6-*Me* (II), m. $60-1^\circ$; 2,6-*Me_2*, m. $101-2^\circ$; 6-*Cl*, m. $111-2^\circ$; 6-*MeO*, semi-solid. 3,3-Dibromothiochromanones, prepd with the calcd. amt. of Br in AcOH , are pale yellow: 6-*Me*, m. 156° (decompn.); 2,6-*Me_2*, m. $111-2^\circ$; 5,6-benzo, m. $115-6^\circ$. Boiling PhNMe_2 converts the above 3-*Br* derivs. into the thiochromones (and their 3-*Br* derivs.), sol. in H_2SO_4 with strong blue or green fluorescence: 6-*Me* (III), b_{12} 194° , m. $69-70^\circ$ (3-*Br* deriv., m. 117° , sol. in H_2SO_4 with pale yellow color); 6-*Cl*, b_{12} $205-10^\circ$, m. $143-4^\circ$; 6-*MeO* (also obtained from $\text{MeOC}_6\text{H}_4\text{SCH}_2\text{CH}_2\text{CO}_2\text{H}$ boiled with POCl_3), m. $110-1^\circ$; 2,6-*Me_2*, m. $120-1^\circ$ (3-*Br* deriv., obtained in 78% yield, m. $134-5^\circ$); 3-bromo 5,6-benzo (2 g. from 4 g. of the 2,3- Br_2 compd.), m. $168-9^\circ$. When boiled in alc. with concd. aq. NH_4OH , II loses HBr and forms III, but with NH_3 in abs. alc., best in the cold, it gives 80% of 3-amino-6-methylthiochromanone, greenish yellow, m. $67-8^\circ$ with loss of NH_3 , insol. in alkalies, sol. in H_2SO_4 at first with a yellow color which is replaced by a strong blue fluorescence, gives with hot HCl III. HCl , always forms III, with loss of NH_3 , in acetylation expts. (even in $\text{C}_6\text{H}_5\text{N}$). II refluxed in aq. alc. NaOH gives 70–5% 4,2-MeAcC₆H₃SH, b_{12} $144-6^\circ$, whose alkali-sol. semicarbazone, m. $199-200^\circ$ and corresponding disulfide, $\text{C}_{18}\text{H}_{18}\text{O}_2\text{S}_2$, m. $173-4^\circ$. The decompn. of the II proceeds quite smoothly and the reaction affords a convenient means of prepg. *o*-acetothiophenols, hitherto only difficultly available. No 2-mercapto-5-methylbenzoic acid could ever be detected among the products of the reaction of NaOH on II but it is obtained in 54% yield from 2,6-dimethyl-3-bromothiochromanone; it m. $155-7^\circ$ and gives with FeCl_3 a transient blue color; *Me ether*, m. $140-1^\circ$; disulfide, from the HS acid and $\text{K}_3\text{Fe}(\text{CN})_6$, m. 291° . With NaOEt at room temp., 2 g. III gives 1 g. 5-methyl-3-hydroxythionaphthene-2-aldehyde (IV), faintly yellowish green, m. $126-7^\circ$, sol. in alkalies with yellow color. $\text{K}_3\text{Fe}(\text{CN})_6$ pptg. the corresponding thioindigo from concd. solns.; alc. solns. are turned

olive-green by FeCl_3 ; boiling acids partially split off the aldehyde group with formation of 3-hydroxy-5-methylthionaphthene-2-aldehyde-5'-methylthioindogen. *Phenylhydrazones* of IV, golden yellow, m. 143° , easily sol. in alkalis. IV is also obtained by NaOEt cleavage of 2-indole-2'-thionaphthene-indigo. 4,5-Benzo-3-hydroxythionaphthene-2-aldehyde (0.7 g. from 1.5 g. 3-bromo-5,6-benzothiochromone and NaOEt , or 3 g. from 5 g. 4,5-benzo-3-hydroxythionaphthene (V) in dry CHCl_3 with HCN and HCl at room temp. and subsequent hydrolysis with boiling NaOH), yellow, m. 147° , forms with hot acids a red condensation product sol. in alc. alkalis with blue-green color; in aq. alkalis with $\text{K}_3\text{Fe}(\text{CN})_6$ it gives the red-brown bis-2,1-naphthothioephene-indigo. The V is obtained in 0.5 g. yield from 5 g. 2- $\text{C}_{10}\text{H}_7\text{SMe}$ with ClCH_2COCl and AlCl_3 . II (5 g.) refluxed 1 hr. in 50 cc. alc. with 10 g. crystd. NaOAc , gave 80% III, while 45 min. refluxing in 10 parts AcOH with 8 g. anhyd. NaOAc yielded 17.5% 6,6'-dimethyl-3,3'-dithiochromanolene, $(\text{CH}_2.\text{S}.\text{C}_6\text{H}_3\text{Me}.\text{CO}.\text{C}=\text{C})_2$, (VI), m. $151-2^\circ$, mol. wt. in C_6H_6 ,

349-80; attempts to prep. it by condensation of I with 6-methylthiochromonol *p*-dimethylaminoanil in the presence of Ac_2O gave 91% of the Ac deriv. of the tautomeric form of the anil, viz. 3-[*N*-dimethylaminophenyl-*N*-acetylamino]-6-methylthiochromone (VII), almost colorless, m. 193° , mol. wt. in CHCl_3 370-405, does not react with $\text{H}_2\text{NCO}.\text{NHNH}_2$, hydrolyzed by boiling 50% H_2SO_4 to 6-methylthiochromonol and *p*- $\text{H}_2\text{NC}.\text{H}_2\text{NMe}_2$ whose *picrate*, yellow, m. 139° ; *N*-propionylamino homolog of VII, obtained in 93% yield with $(\text{EtCO})_2\text{O}$ as the condensing agent, almost colorless, m. $157-8^\circ$. 3,3'-Dithiochromanolene, from 3-bromothiochromanone and $\text{Ac}_2\text{O}.\text{AcOH}$ (yield, 7%), faintly yellowish, m. $170-1^\circ$. 6,6-(MeO)₂ deriv. (yield, 23.5%), yellow, m. $168-9^\circ$. 3-Bromo-6-chlorothiochromanone gave no dimol. compd., but only 6-chlorothiochromone; likewise, 3-bromo-6-methylchromanone yielded only 6-methylchromone, and β -bromo- α -tetralone, m. $40-1^\circ$ (described by Strauss, C. A. 15, 1896, as an oil), yielded α -tetralone and α - and β -naphthol. Dibromide of VI (0.8 g. from 0.6 g. VI in AcOH with the calcd. amt. of Br), yellow, darkens about 130° , m. $290-5^\circ$ (carbonization), reddens on standing and, with loss of HBr , on boiling a short time with AcOH or high boiling solvents (PhNO_2). These dibromides boiled a short time with $\text{C}_6\text{H}_5\text{N}$ or quinoline yield the corresponding 3,3'-dithiochromones (also obtained, although less pure, from the dithiochromanolenes with concd. H_2SO_4): unsubstituted, brown-red; 6,6'- Me_2 , brown-red needles, traces of which impart a blue-red fluorescence to CS_2 or CHCl_3 and which dissolve in H_2SO_4 with yellow color changed to green by absorption of H_2O , while the NaOH suspension forms with $\text{Na}_2\text{S}_2\text{O}_4$ a yellow vat dyeing cotton in faint blue-red shades; 6,6'-(MeO)₂, blue-red. 3-Benzylidene-6-methylthiochromanone (VII), best obtained from I and 1.5 mols. BzH treated hot with a few drops of concd. $\text{AcOH}.\text{HBr}$, gives in CS_2 with 1 mol. Br_2 a dibromide, light yellow, m. 167° (loss of HBr), regenerates VII when boiled with PhNMe_2 ; the monobromide (phenyl-[6-methylthiochromonyl-3]-bromomethane), which is obtained when the dibromide is heated at its m. p. and the resulting resin is crystd. from Et_2O (3.7 g. from 9 g. of the dibromide), m. $115-6^\circ$. If the resin is recrystd. from MeOH there is obtained phenyl-[6-methylchromonyl-3]carbinyl *Me ether*, m. $118-9^\circ$; *Et ether*, m. $124-5^\circ$; *acetate*, from the bromide with boiling $\text{AcOH}.\text{NaOAc}$, m. $120-1^\circ$. The bromide with $\text{C}_6\text{H}_5\text{N}$ in C_6H_6 forms a pyridinium salt, $\text{C}_{22}\text{H}_{18}\text{ONBrS}$, m. $137-8^\circ$, and with PhSH a thiophenol ether, m. $129-30^\circ$. The above *Et ether*, cautiously added to concd. H_2SO_4 , produces a blue-red soln. which becomes colorless on standing and H_2O ppts. a substance, possibly a di-ether of the carbinol, insol. in all the usual solvents except CHCl_3 , does not m. 290° . The thiochromanones are reduced by the Clemmensen method to the thiochromans which with the calcd. amt. of KMnO_4 give the corresponding sulfones: Thiochroman, b_{10} $124-5^\circ$ (sulfone, m. $87-8^\circ$); 6-*Me deriv.*, b_{12} 137° (sulfone, m. 81°); 6,8-*Me*₂ deriv., b_{12} $146-7^\circ$ (sulfone, m. 101.2°). The thiochromanolens were prepd. from the thiochromanones with organo-Mg compds. and converted into the α -chromenes by vacuum distn. over P_2O_5 ; both dissolve in H_2SO_4 with deep blue color; the latter are oils of characteristic odor which resinify on standing, especially in the air. Thio- α -chromanols (% yields in parentheses): 4-*Me*, m. $109-10^\circ$ (65); 4,6-*Me*₂, m. $119-20^\circ$ (80); 4,6,8-*Me*₃, m. $46-9^\circ$; 4-ethyl-6-methyl, m. $52-3^\circ$, b_{11} $159-60^\circ$; 4-phenyl-6-methyl, m. $112-3^\circ$. α -Thiochromenes: 4-*Me*, b_{12} 138° (85%); 4,6-*Me*₂, b_{12} $145-6^\circ$ (80); 4,6,8-*Me*₃, b_{12} $155-7^\circ$; 4-ethyl-6-methyl, b_{12} $158-60^\circ$; 4-phenyl-6-methyl, b_{12} 211° , m. $47-8^\circ$. C. A. R.

Spectrochemistry of the thiochromans, α -thiochromenes and thiochromanones. F. KROLLPFER. Ber. 58B, 1677-80 (1925).—The values given below are, resp., t° (temp. at which the measurements were made), d_n , n for α , He, β and γ , and $E\lambda$ for α , D, β - α and γ - α (the last 2 expressed in %). Thiochromans: unsubstituted, 17.3° , 1.1267, 1.60943, 1.61610, 1.63289, 1.64835, 0.40, 0.41, 30, 32; 6-*Me*, 15.4° , 1.0907,

Quinoline derivatives. I. Synthesis of [2-phenyl-4-quinolylmethyl]amine. HANNS JOHN. *Ber.* 58B, 1489-91 (1925).—*N*-Phthalyl-[2-phenyl-4-quinolylmethyl]amine, from 14 g. o -H₂NC₆H₄COCH₂N(CO)₂C₆H₅ and 6 g. PhCOMe refluxed 8 hrs. in aq. alc. NaOH, seps. from H₂O or EtOH with solvent of crystn., m. 261°, converted by refluxing in concd. HCl into the *di-HCl* salt, m. 232-5° (decompn.), of [2-phenyl-4-quinolylmethyl]amine, which sometimes seps. in long needles soon changing in the air or in a desiccator to a reddish thick oil; usually, however, it seps. directly as an oil which cannot be made to solidify. *Mono-HCl* salt, gives with HgCl₂ a voluminous ppt. chang-

ing to druses of needles, with K_2CrO_4 , indistinct leafy crystals, with $K_3Fe(CN)_6$, rhombic platelets. In H_2SO_4 with I-KI the base yields a brown oil solidifying to needles. *Chloroplatinate*, orange, becomes gray 205°, black 220°, does not m. 287°. C. A. R.

2-Phenyl-3-methoxyquinoline-4-carboxylic acid [3-methoxyatophan]. W. DILTHEY and CL. THELEN. *Ber.* 58B, 1588-9 (1925).— $PhCOCH_2OMe$ boiled in aq. or alc. NaOH with isatin gives almost quant. *2-phenyl-3-methoxyquinoline-4-carboxylic acid*, almost colorless, m. 225°, easily sol. in alkalis and alkali carbonates and also in mineral acids, converted quant. by boiling in C_6H_6 with $AlCl_3$ into the 3-HO acid (I), m. 204-5°, which is amorphous when dry and very difficultly sol. in most solvents, but is easily sol. in hot $PhNO_2$ and seps. in a deep yellow amorphous form becoming lighter in color on standing (if the soln. is not quickly cooled, the I loses CO_2). Although I is a weak acid whose alkali salts have an alk. reaction, it dissolves quite readily in alkalis with light greenish fluorescence and mineral acids give after some days a light yellow ppt. of microneedles with $3H_2O$; both the color and the cryst. structure depend on this H_2O of crystn. *Base salt* of I, very faintly yellowish needles with $6H_2O$, loses $3H_2O$ easily, the next 2 less easily and the 6th mol. only with simultaneous loss of CO_2 . I on long boiling in $PhNO_2$, the 3-MeO acid with HCl at 160°, give 2-phenyl-1-hydroxyquinoline, m. 218-20°; HCl salt, m. 261° (Barginelli and Berlingozzi, C. A. 17, 2287, give 210-2° for the base, 243-5° for the HCl salt), insol. in carbonates but sol. in caustic alkalis with strong green fluorescence. C. A. R.

Homologs of 2,2'-diquinolyl. E. J. V. CONOLLY. *J. Chem. Soc.* 127, 2083-5 (1925).—6-Methylquinoline (70 g.) and 7 g. Na, heated 2 hrs. at 100° and 7-8 hrs. at 150-60°, give about 37 g. *6,6'-dimethyl-2,2'-diquinolyl* (I), m. 202.5-3°, mol. wt., 279 (Rast's method); *HCl salt*, minute needles; *picrate*, yellow, m. 282-3° (decompn.); *ethiodide*, m. 277-8° (decompn.). *7,7'-Dimethyl-2,2'-diquinolyl*, m. 208-9°; *picrate*, yellow, m. 285-6° (decompn.); *ethiodide*, Au-yellow, m. 274-5° (decompn.). The yield of *8,8'-dimethyl-2,2'-diquinolyl*, m. 147-7.5°, is very small; *picrate*, yellow, m. 264-5°; the ethiodide could not be obtained. 2-Bromo-6-methylquinoline, m. 117-8°, yields a yellow *picrate*, m. 140.5°, and an *ethiodide*, yellow, m. 110.1°. Attempts to prep. I from this by the Fittig-Wurtz or the Grignard reactions were unsuccessful. C. J. W.

Synthesis of substituted 4-keto-1,2,3,4-tetrahydroquinolines and an attempt to synthesize 4-keto-1,2,3,4-tetrahydroisoquinoline. G. R. CLEMO and WM. H. PERKIN, JR. *J. Chem. Soc.* 127, 2297-307 (1925); cf. C. A. 18, 3382.—*Toluene-p-sulfonyl-β-o-toluidinopropionic acid*, m. 127-8°, results in 28.5 g. yield from 52.2 g. $MeC_6H_4NHSO_3C_6H_4Me$ and 22 g. $ClCH_2CH_2CO_2H$ in 8% NaOH. Heated with $POCl_3$ at 100° for 15 min., there results *4-keto-8-methyl-1,2,3,4-tetrahydroquinoline*, yellow, m. 92°, gives solns. in H_2O or C_6H_6 with a green fluorescence and its *toluene-p-sulfonyl deriv.* m. 147-8°. The latter, allowed to stand overnight with H_2SO_4 , gives *β-o-toluidinopropionio-o-toluide*, m. 126°. *Toluene-p-sulfonyl-β-m-toluidinopropionic acid*, m. 103° (yield, 19 g.). $POCl_3$ gives a mixt. of *toluene-p-sulfonyl-3-chloro-4-keto-7-methyl-1,2,3,4-tetrahydroquinoline*, m. 138°, gives a deep violet soln. in concd. H_2SO_4 , and the corresponding *5-Me deriv.*, m. 98-100°. Hydrolysis with $AcOH-HCl$ gives *4-keto-7-methyl-1,2,3,4-tetrahydroquinoline*, bright yellow, m. 109° (*toluene-p-sulfonyl deriv.*, m. 98°), and the *5-Me deriv.*, yellow, m. 104-5° (*toluene-p-sulfonyl deriv.*, m. 136°). *Toluene-p-sulfonyl-β-p-toluidinopropionic acid*, m. 116-7°; treated with P_2O_5 and $C_6H_5Me_2$, it yields *toluene-p-sulfonyl-4-keto-6-methyl-1,2,3,4-tetrahydroquinoline*, m. 136-7°; $POCl_3$ gives the *3-Cl deriv.*, m. 176-7°. Either compd., on hydrolysis with acids, yields *4-keto-6-methyl-1,2,3,4-tetrahydroquinoline*, yellow, m. 85-6°. *3-Benzylidene deriv.*, yellow, m. 221-5°; this combines with 2 atoms of Br, and the dibromide boiled with $MeOH-KOH$, gives a *mono-Br deriv.*, m. 194-5°. The Cl deriv., refluxed with 20% $MeOH-KOH$, gives *4-methoxy-6-methylquinoline*, b₁₈ 195°, m. 51°. *Toluene-p-sulfonyl-β-p-anisidinopropionic acid*, m. 81-2°. P_2O_5 in $C_6H_5Me_2$ gives *toluene-p-sulfonyl-6-methoxy-4-keto-1,2,3,4-tetrahydroquinoline*, m. 124-5°; $POCl_3$ gives about 90% of this deriv. with 10% of the 3-Cl deriv.; hydrolysis gives *6-methoxy-4-keto-1,2,3,4-tetrahydroquinoline*, bright yellow, m. 112°. There is also formed by the action of $POCl_3$ a small amt. of a compd., $C_{17}H_{14}O_3NClS$, m. 235°, which may be *toluene-p-sulfonyl-3-chloro-6-methoxydihydroquinoline*; the concd. H_2SO_4 soln. shows an intense pale blue fluorescence. *Toluene-p-sulfonyl-β-p-phenetidinopropionic acid*, m. 97°. P_2O_5 gives a small amt. of *toluene-p-sulfonyl-6-ethoxy-4-keto-1,2,3,4-tetrahydroquinoline*, m. 114-5°; $POCl_3$ gives a mixt. of this deriv. with the 3-Cl deriv., yielding on hydrolysis the free quinoline, canary-yellow, m. 60°; the yellow solns. in org. solvents show a green fluorescence. *6-Hydroxy-4-keto-1,2,3,4-tetrahydroquinoline*, deep yellow, m. 163-4°, from the MeO deriv. and concd. HCl. *Toluene-p-sulfonylbenzylaminoacetic acid*, m. 137-8°; *ester*, m. 51°. C. J. WEST

Synthesis of *dl*-dicentrine. R. D. HAWORTH, WM. H. PERKIN, JR., AND JOHN RANKIN. *J. Chem. Soc.* **127**, 2018-23(1925).—*1-Veratryl-6,7-methylenedioxydihydroisoquinoline methiodide* (I), straw-yellow, m. 239-40°; the crude product probably contains some *6,7-methylenedioxy-3',4'-dimethoxy-1-benzoyl-3,4-dihydroisoquinoline methiodide*, amber-colored, m. 232-3° (decompn.). Crude I is transformed into the more sol. methochloride by AgCl, then reduced with Zn and dil. H₂SO₄ and finally electrolytically (5 amps. for 12 hrs.), giving *1-veratrylhydrohydrastinine* (II), oily; *HCl salt*, m. 215-6°; *III salt*, m. 180-2°; *picrate*, orange-yellow, m. 188-9°. HNO₃ in AcOH gives the *6'-nitro deriv.* of II, buff, m. 118°; *III salt*, pale yellow, m. 213°; *picrate*, lemon-yellow, m. 192°. The *6'-amino deriv.* is an oil, whose *di-HCl salt*, m. 250° (decompn.); FeCl₃ gives a deep blue color. The diazo soln. in 10% H₂SO₄, treated with Cu powder, gives *dl-centrine*, cream-colored, m. 178-9°; the colorless concd. H₂SO₄ soln. soon becomes reddish violet. The *HCl salt* darkens at 250° and m. 263-5° (decompn.); *methiodide*, m. 228-9°; *picrate*, orange, m. 188-9°. The synthetic base exhibits all those color reactions which are characteristic of the naturally occurring dicentrine. C. J. W.

Pyrimidines. CIII. The discovery of 5-methylcytosine in tuberculinic acid, the nucleic acid of the tubercle bacillus. T. B. JOHNSON AND R. D. COGHILL. *J. Am. Chem. Soc.* **47**, 2838-44(1925).—The base fraction of the hydrolytic products of tuberculinic acid pptd. by phosphotungstic acid contains, in addn. to cytosine, 5-methylcytosine, which is sepd. as the picrate; the orthorhombic Au-yellow crystals show parallel extinction between crossed nicols; they show a high birefringence, the 2 indices detd. being 1.44 and greater than 1.80. The crystallographic data for the monoclinic cytosine picrate are also given, the indices of this being 1.50 and greater than 1.80.

C. J. WEST

Condensation of amidines with ethoxymethylene derivatives of β -ketonic esters, β -diketones and cyanoacetic ester. P. C. MITTER AND NIRMALANANDA PALIT. *Quart. J. Indian Chem. Soc.* **2**, 61-70(1925); cf. *C. A.* **18**, 86.—The following derivs. of 4-*keto-5-cyano-1,4-dihydropyrimidine* were prepd: *2-Ph*, m. 295°, in a very poor yield from benzamidine-HCl and EtOCH₂:C(CN)CO₂Et; the corresponding acid, m. 271° (decompn.). *2-Tolyl deriv.*, m. 303-4°; the acid, m. 282°. *2-Anisyl deriv.*, m. 286°; the acid, m. 271°. *2- β -Naphthyl deriv.*, yellow, m. 305.6°; the acid, m. 291°. *Et 4-methyl 2-aminopyrimidine-5-carboxylate*, m. 222°, from guanidine and EtOCH₂:C(CN)CO₂Et; hydrolysis gives the free acid, m. 256-8° (decompn.). *Et 2-anisyl-4-methylpyrimidine-5-carboxylate*, m. 80°; the free acid, m. 232-3°. The *2- β -naphthyl deriv.*, m. 118° and gives an acid, m. 245-6°. *5-Acetyl-2-anisyl-4-methylpyrimidine*, m. 113-5°, from anisamidine and Ac₂C:CHOEt; *2- β -naphthyl deriv.*, m. 151-3°. *Et 4-keto-2-amino-1,4-dihydropyrimidine-5-carboxylate*, m. 285°, from guanidine and EtOCH₂:C(CN)CO₂Et; the free acid, m. 238° (decompn.); the intermediate product in the reaction is *Et ethoxymethylenemalonoguanidic acid*, m. 295°, which gives, with 50% HCl, *malonoguanidic acid*, m. 254° (decompn.). *Et 4-keto-2-anisyl-1,4-dihydropyrimidine-5-carboxylate*, m. 222-4°; the *2-naphthyl deriv.*, m. 213-5°.

C. J. WEST

Quinazolines from acetylated *o*-aminobenzohydrazides. GUSTAV HELLER, ERNST GÖRING, JOHANNES KLOSS AND WILLI KOHLER. *J. prakt. Chem.* **111**, 36-53(1925).—AcNH.C₆H₄.CO₂Et and N₂H₄ give 66% of 2-methyl-3-amino-4-quinazoline, m. 150°. *o*-Aminobenzacetylhydrazide (I), m. 181°; NaNO₂ and HCl give 3-acetaminobenzazimide, m. 206° (decompn.). Ac₂O transforms this into 2-methyl-3-acetamino-4-quinazoline, m. 174°. *o*-Benzoylaminobenzoic acid acetylhydrazide, m. 236° (decompn.), in 80% yield from I and BzCl; heated at 250° it gives 2-phenyl-3-acetamino-4-quinazoline, m. 122°. *o*-Aminobenzobenzoylhydrazide, m. 178° (70% yield); heated at 210-20°, it gives 2-phenyl-3-amino-4-quinazoline. 3-Benzoylaminobenzazimide, m. 205-6° (decompn.). *o*-Acetylaminobenzoic acid benzoylhydrazide, sinters 108°, m. 115° (decompn.); at 180° it yields 2-methyl-3-benzoylamino-4-quinazoline, m. 182°. The corresponding *o*-Bz deriv., m. 239° (decompn.), heated to 250°, gives 2-phenyl-3-benzoylamino-4-quinazoline, m. 202°. *o*-[*m*-Nitrobenzoyl]aminobenzoic acid acetylhydrazide, m. 205° (decompn.). 2-[*m*-Nitrophenyl]-3-acetamino-4-quinazoline, crysts. with 1H₂O, m. 183°. HCl splits off the Ac group, giving 2-*m*-nitrophenyl-3-amino-4-quinazoline, m. 222°. *o*-Aminobenzoic acid [*m*-nitrophenyl]hydrazide, m. 192°. [*m*-Nitrobenzoyl]aminobenzoic acid [*m*-nitrophenyl]hydrazide, pale yellow, m. 217°. 3-[*m*-Nitrobenzoyl]aminobenzazimide, m. 185° (decompn.). *o*-Acetylaminobenzoic acid [*m*-nitrophenyl]hydrazide, m. 167° (decompn.), giving 2-methyl-3-[*m*-nitrobenzoyl]amino-4-quinazoline, m. 231°. [*m*-Nitrobenzoyl]amino[benzoic acid benzoylhydrazide, decomp. 217°, forming 2-[*m*-nitrophenyl]-3-benzoylamino-4-quinazoline, m. 221°. Benzoylaminobenzoic acid [*m*-nitrophenyl]hydrazide, m. 236°; at 260° it gives 2-phenyl-3-[*m*-nitrobenzoyl]aminoquinazoline, m. 198°. Propionylaminobenzoic acid acetylhydrazide, m. 160° (decompn.), giving

2-ethyl-3-acetylaminquinazolone, m. 135°. *o*-Aminobenzoic acid propionylhydrazide, m. 137°; the triazine deriv., m. 181°. *o*-Acetylaminobenzoic acid propionylhydrazide, m. 167° (decompn.); 2-methyl-3-propionylaminquinazolone, m. 170°. Methylanthranilic acid hydrazide, m. 141–2°; yield, 70%. The Bz deriv., m. 192°. The Ac deriv., m. 152°. Methylacetylthranilic acid hydrazide, m. 234–5°; the HCl soln. with NaNO₂ gives an emerald-green compd., C₁₁H₁₂O₃N₄, decomp. at 250–60°. 3-Acetylphenoneaminobenzazimide, pale yellow, m. 168.5°. 1-Acetylaminobenzoic acid hydrazide, m. 202–3° (decompn.). 2-Methyl-3-acetylphenonamino-4-quinazolone, m. 195°. 3-Aminobenzazimide, gray, m. 152–3° (decompn.). Zn dust in AcOH gives benzazimide. C. J. WEST

Chemical reactivity and conjugation. II. The reactivity of the 2-methyl group in the 4-quinazoline series. I. M. HEILBRON, F. N. KITCHEN, R. B. PARKES AND G. D. SUTTON. *J. Chem. Soc.* 127, 2167–75 (1925); cf. C. A. 18, 267.—2,3-Dimethyl-4-quinazolone (I) contains a reactive Me group, the following condensation products being prepd.: 2-styryl-3-methyl-4-quinazolone, pale yellow, m. 167°; 4'-methoxy-2-styryl, bright yellow, m. 146°, giving an orange soln. in dil. HCl; 3',4'-dimethoxy-2-styryl, yellow, m. 208°; 3',4'-methylenedioxy-2-styryl, bright yellow, m. 185°; 4'-dimethylamino-2-styryl, orange-red, m. 175°. *o*-MeNHC₆H₄CO₂H gives a carboxy deriv., m. 108°. The acid in ClCO₂Et and AcCl gives quant. methylisatoic anhydride, m. 180°, which, with 0.88% NH₄OH, gives quant. *o*-MeNHC₆H₄CONH₂, m. 162°, from which Ac₂O gives an excellent yield of 1,2-dimethyl-4-quinazolone (II), m. 203°. 2-Styryl-1-methyl-4-quinazolone, cream-colored, m. 245°; 4'-MeO deriv., bright yellow, m. 94° (contains 2H₂O); anhyd., m. 156°; 3',4'-methylenedioxy deriv., yellow, m. 264°; 4'-dimethylamino deriv., orange, m. 274°. 5-Methoxyacetylthranil, m. 124°, in quant. yield from the acid and Ac₂O; with excess NH₄OH (0.88) there results 6-methoxy-2-methyl-4-quinazolone, m. 270°, and with MeNH₂ the corresponding 2,3-di-Me deriv., m. (with 1H₂O), 87°; anhyd., 133°; the latter does not condense with aromatic aldehydes. 5-Methoxymethylanthranilic acid, yellow, m. 163°; the amide, m. 145°, results by the action of NH₄OH upon 6-methoxymethylisatoic anhydride, m. 233°. 6-Methoxy-1,2-dimethyl-4-quinazolone, m. 220°; piperonal gives the 3',4'-methylenedioxy-2-styryl deriv., yellow, m. 284°. 7-Methoxy-1,2-dimethyl-4-quinazolone, m. 193° or with 1H₂O, m. 135°; 3',4'-methylenedioxy-2-styryl deriv., yellow, m. 280°; 4'-dimethylamino deriv., bright red, m. 266°. 7-Methoxy-2-methyl-4-quinazolone, m. 272°; Me₂SO₄ gives the 2,3-di-Me deriv., m. 149° or with 1H₂O, m. 80°; 3',4'-methylenedioxy-2-styryl deriv., yellow, m. 193°. 5-Chloro-2-amino-4-methoxytoluene, m. 112°; Ac deriv., m. 183–4°. The II appear to be more re-

active than the I, probably because of the presence of the conjugated system O:CN:CMe; a certain retardation of activity is found in the case of the 7-MeO deriv. of II, thus showing that neutralization effects, although not sufficient to prevent reaction, do nevertheless come into play. C. J. WEST

Dyes derived from oxalyldibenzyl ketone. I. Azine and azonium derivatives. G. C. CHAKRAVARTI. *Quart. J. Indian Chem. Soc.* 2, 71–6 (1925).—The following condensation products of oxalyldibenzyl ketone were prepd.: *o*-phenylenediamine, bright pink, m. 251°; concd. H₂SO₄ soln., deep pink, turning brown on diln.; dyes wool yellow from a neutral bath. 1,3,4-*o*-Tolylenediamine, yellow, m. 285°; dyes wool brown. 1,3,4,5-Bromotolylenediamine, ochre-colored, m. 300°; concd. H₂SO₄ soln., deep red; dyes wool pink. 1,2-Naphthylenediamine, deep yellow, m. 288°; concd. H₂SO₄ soln., violet; dyes wool gamboge shades. 1,2,3-*o*-Phenylenediaminesulfonic acid, yellow. 1,2-Diamino-8-naphthol-6-sulfonic acid, sparingly sol. in hot H₂O. 1,2,4-Naphthylenediaminesulfonic acid, yellow, amorphous ppt. 1,6,3,4-Chlorotolylenediamine, m. above 300°. 1-Amino-2-phenylaminonaphthalene, isolated as the HCl salt, brown, m. 195°; and the HNO₃ salt, scarlet-red, m. above 300°; H₂SO₄ soln., dark brown; dyes wool light brown.

Supposed formation of 1,2,4-oxadi-imine rings from nitroso compounds and methylene-arylamines. G. N. BURKHARDT, ARTHUR LAPWORTH AND E. B. ROBINSON. *J. Chem. Soc.* 127, 2234–6 (1925).—Polemical with Farrow and Ingold (C. A. 19, 978). C. J. WEST

The influence of chemical constitution on the thermal properties of binary mixtures. VI. Triazine and benzene derivatives. PAUL PASCAL. *Bull. soc. chim.* 37, 836–40 (1925).—The 5 binary systems:—(1) C₆H₅Ph₃-triphenyltriazine; (2) Et trimesate-Et triazinetricarboxylate; (3) methylidiphenyltriazine-triphenyltriazine; (4) methylidiphenyltriazine-C₆H₅Ph₃; (5) triphenyltriazine-Et triazinetricarboxylate were investigated. All the systems form solid solns. (complete diagrams given). M. A. YOUTZ

Lupine studies. IV. Isolation of *d*-lupanine from *Lupinus kingli* (S. Watson).

J. F. COUCH. *J. Am. Chem. Soc.* **47**, 2584-7(1925).—The abstract in *C. A.* **19**, 3271, should be corrected by eliminating the sentence: "Two other alkaloids were isolated and analyzed as the Au salts." These alkaloids are identical with *d*-lupanine.

C. J. WEST

The resins of lead. ROGER UZAC. *Bull. soc. chim.* **37**, 1194-6(1925).—The resins of Pb may be prepd. (1) by heating rosin with litharge, minium or white lead, or, (2) by double decompn. between an aq. soln. of a resinous soap and of a Pb salt; (1) gives an acid resin which is a liquid; (2) gives a neutral resin which appears as a gel or in the form of white flakes. By detn. of the *index of neutrality* the normal resin of Pb is shown to be alk. and the neutral or acid resins are probably contaminated with free resin which is acidic.

REYNOLD C. FUSON

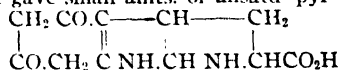

Cyamarin and strophanthidin. A. WINDAUS, G. REVEREY AND A. SCHWIEGER. *Ber.* **58B**, 1509-14(1925), cf. *C. A.* **9**, 2378; Jacobs and Collus, *C. A.* **19**, 1142.—In an investigation undertaken to det. whether the various plant glucosides with a digitalis action are closely related chemically and have structures similar to those of cholesterol and the bile acids, W. with Bandte (*C. A.* **17**, 3746) obtained from digitaligenin a hydroxylactone $C_{24}H_{38}O_3$ and a lactone $C_{24}H_{36}O_3$ and to Reverey was assigned the task of prep. from strophanthidin (cymarigenin) (I) the next lower homolog of hexahydro-digitaligenin, the hydroxylactone $C_{23}H_{36}O_3$ (II), which he succeeded in doing (*Diss. Göttingen*). Since then, Jacobs and his coworkers (cf. also Thoms and Unger, *C. A.* **19**, 379) have shown that the formula of I is $C_{23}H_{36}O_6$, not $C_{23}H_{30}O_6 \cdot H_2O$, and that the "anhydrostrophanthidin" (III) of W. and Hermanns, obtained by treating I in $CHCl_3$ with PCl_5 gas, shaking with H_2O to remove the HCl and crystg. the product from MeOH, is really dianhydrostrophanthidin Me hemiacetal, $C_{24}H_{36}O_4$ (IV). Schwieger has now found that the true dianhydrostrophanthidin (V) gives the same II as the III used by R. in the mistaken belief that it was V, as in the hydrogenation with AcOH and Pt sponge the hemiacetal is hydrolyzed. In the catalytic hydrogenation of V the compn. of the resulting mixt. depends greatly on the nature of the catalyst; with Pt previously treated with H there is obtained chiefly the *hexahydro deriv.* $C_{23}H_{34}O_4$ (VI), while Pt laden with O gives also the *octahydro* (VII) and the *desoxy deriv.* $C_{23}H_{36}O_3$ (VIII). VI, formed by satn. of the 3 double bonds, is a satd. hydroxyketolactone, and VIII, formed by the further addn. of 1 mol. H_2 at the C O group, is a satd. dihydroxylactone; on cautious oxidation with CrO_3 it smoothly regenerates VI, in which the C O group is reduced by the Clemmensen method to CH_2 ; the resulting alc. (VIII), from its resistance to oxidizing agents, is probably tertiary, i. e., is a satd. monohydroxylactone; it distills *in vacuo* without decompn. The above results show that I contains like cholesterol a tetracyclic system, is an unsatd. hydroxylactone like the genus of the digitalis glucosides but differs from them in contg., besides three HO groups, a C O group in addn., and also in having 1 atom less of C. VI, m. 208° , does not give the Liebermann-Burchard reaction. VII, m. $265-6^\circ$, also does not give the L.-B. reaction, *acetate*, m. 185° . VIII, m. 224° , gives no color with $Ac_2O \cdot H_2SO_4$.

C. A. R.

A chloroform-insoluble glucoside from digitalis leaves, gitoxin. A. WINDAUS AND G. SCHWARTE. *Ber.* **58B**, 1515-9(1925).—Kiliani (*C. A.* **9**, 1336) studied a glucoside, obtained in the Merck factory as a by-product in the prepn. of digitoxin, which, although originally sol. in $CHCl_3$, became insol. in the course of manuf. Although it showed the same slight soly. in alc., $CHCl_3$ and H_2O as Kraft's anhydrodigitalin (*C. A.* **6**, 1653) and gave the same very characteristic color reaction with Fe^{+++} salts and H_2SO_4 , Kiliani concluded, from differences in the compn. of the 2 substances, that they are not identical. These differences, however, were probably due only to his previous treatment of the material analyzed; he pptd. the Merck glucoside from MeOH- $CHCl_3$ with Et_2O , and as the 1st fractions were still contaminated with coloring matter, he analyzed only the last, colorless fraction which contains only the most sol. constituents and is relatively poor in the difficultly sol. main component. W. and S. have now carefully recrystd. both substances and obtained from each in good yield substances, m. 266° , almost insol. in most solvents and having the same compn.; no difference whatever could be detected between them and on hydrolytic cleavage both gave the same products, so that there is no doubt that they are identical; the name *gitoxin* (I) is suggested for the compd. Its compn. is C 62.22, H 8.15%; its mol. wt. could not be detd. on account of its insoly. but it titrates as a lactone with hot 0.1 N alkali, giving an equiv. wt. of about 770. The formula best agreeing with these results is $C_{42}H_{68}O_{13}$ or $C_{42}H_{66}O_{14} \cdot H_2O$, which is also rendered probable by a study of its decompn. products, *gitoxigenin* (II) and *digitoxose* (III). II, $C_{24}H_{36}O_6$, is obtained in 48% yield and III, $C_6H_{12}O_4$, in the proportion of about 3 mols. to 1 of II. II contains a lactone and three HO groups and a double bond; with cold concd. acids it loses 2 mols. H_2O and forms a triply unsatd. monohy-

droxylactone, *dianhydrodigitoxigenin*, $C_{24}H_{32}O_8$ (IV), identical with the digitaligenin (V) obtained from *Digitalinum verum*. The latter glucoside and I are therefore very closely related; both contain an aglycon, $C_{24}H_{36}O_8$, combined in the 1 case with glucose and digitalose, in the other with III; as with cymarín and strophanthin Kombé, the only difference between the 2 glucosides is probably in the sugar component. III m. 108–9°. II, m. 224–5° (decompn.), dissolves in about 500 parts AcOEt at 18°, gives with $FeCl_3 \cdot H_2SO_4$ a golden yellow, then violet-red color, does not react with NH_2OH , yields with $BzCl$ in C_6H_5N a *di-Bz deriv.*, m. 262°, mol. wt. in camphor 589–93. In AcOH with Pt sponge, II absorbs 1 mol. H_2 , giving a substance, m. 226°. IV, m. 209–10°, does not depress the m. p. of V; acetate, m. 208° (also when mixed with the acetate of V), mol. wt. in camphor 429. With H and Pt sponge in AcOH, IV gives hexahydrodigitaligenin, m. 186–7°; acetate, m. 156°. C. A. R.

The constitution of proteins. N. TROENSEGAARD. *Z. angew. Chem.* **38**, 623–6 (1925).—A paper giving various partly developed lines of evidence that proteins are probably not built up of amino acids as formerly supposed but largely of pyrrole, pyrrolidine and pyridine rings condensed into systems of 2, 3, or more, and contg. O as OH. Such substances would probably be easily split into amino acids. Against the older theory of their compn are several facts: (1) Hydrolysis of proteins often gives only a relatively small amt. of the N as amino acids. (2) While all proteins have nearly the same elementary compn., that of the amino acids varies greatly. (3) The proportions of the various acids are not such as to lead to any classification of the proteins from which they are derived or to any possible scheme of combination in the manner characteristic of polypeptides ($RNHCOR'$, etc.). (4) Ring compds. have been found among the amino acids, *i. e.* the glyoxaline ring in histidine, the pyrrolidine ring in pyrrolidinecarboxylic acid, and the indole group in tryptophan. Exptl. work was done using gliadin recrystd. from 60% EtOH, gelatin, casein and blood protein. Free NH_2 and NH groups in the products were detd. by the method of Van Slyke, using HNO_3 , followed by Sørensen's formol titration method. The difference gave the imino N. It was found possible to acetylate the proteins and obtain products which could be hydrolyzed to volatile bases with KOH in anhyd. MeOH. The hydrolysis products were sepd. into various basic and acid substances or fractions by distn., and by soly. differences in CS_2 , Et_2O and C_6H_6 . Some of the basic fractions from acetylgladin gave good yields of pyrrole upon distn. with 50% KOH. Reduction with Zn and HI or Mg and AcOH was too violent but Na and AmOH gave small amts. of unsatd pyrroles. An acid was sepd. to which the constitution

was tentatively assigned. It contained no aliphatic amino groups, was stable to acids, but was easily split up by alkalis. It reacted readily with MeI, adding to the N atoms and also some MeO compd being formed. No details are given but the original should be consulted for interesting descriptions of the above and other results M. A. Y.

Derivatives of *p*-cymene (SARGENT, HIBBARD) **25**. Catalytic splitting of acetoacetic acid by strong acids and bases (EULER, ÖLANDER) **2**. Study of the physical properties of nitromethane (WILLIAMS) **2**.

Tetraalkyl lead. W. S. CALCOTTE. U. S. 1,559,405, Oct. 27. Pb-Na alloy is treated with EtBr or other alkyl halide in the presence of triethylamine or dimethylaniline or other catalyst of the type used for the Grignard synthesis and the mixt. is subjected to the action of a sufficient quantity of a reducing agent such as nascent H formed by adding H_2O to effect reduction to a Pb dialkyl. The quantity of reducing agent used is substantially less than the equiv. of 4 atoms of nascent H for each mol. of Pb used. The Pb dialkyl thus formed is heated to produce tetraalkyl lead.

Lead tetraalkyls. K. WILLIAMS and H. W. DAUDT. U. S. 1,550,940, Aug. 25. Pb in the form of an alloy with Na is caused to react with an alkyl bromide, *e. g.*, EtBr, in the presence of a small quantity of H_2O , EtCN and pyridine at 83–85° for 8 hrs., and the reaction mass is mixed with a strong base, *e. g.*, a large quantity of NaOH soln.

Methanol, etc. A. MITTASCH, M. PIER and K. WINKLER. U. S. 1,558,559, Oct. 27. A mixt. of C oxides with at least about an equal vol. of H at a temp. of 200–600° and under a pressure of 50 atm. or higher is passed over a catalyst contg. an intimate mixt. of at least 2 oxides (non-reducible to metals under the conditions of the process) of metals belonging to different periodic groups such as Zn and Cr, Zn and U, Zn and V,

Zn and W, Mg and Mo, or Ce and Mn. The more basic oxide is used in larger proportion and Fe and Ni should be absent.

Methanol and other oxygenated organic compounds. M. PIER, W. RUMPF, F. LAPPE and G. STERN. Can. 254,987, Oct. 27, 1925. In the manuf. of MeOH by the catalytic reduction of CO at elevated temp. and pressure the app. used is lined with a metal or alloy resistant to CO at the temp. of working. Cu, Ag, Al and their alloys or special steel contg. Cr, Mn, W, Mo or V are specified.

Aldehyde-ammonia. F. W. SKIRROW and G. O. MORRISON. U. S. 1,551,176, Aug. 25. AcH or other "fatty aldehyde" and NH_3 , in approx. equimol. proportions, are passed into a satd. aq. soln. of aldehyde-ammonia at a temp. below 50° .

Alkali metal xanthates. R. B. CROWELL and G. F. BRECKENRIDGE. U. S. 1,559,504, Oct. 27. NaOH or other alkali metal hydroxide is caused to react with alc. and CS_2 in kerosene, gasoline, toluene or other liquid hydrocarbon medium which is chem. inert to the other ingredients.

Butyraldehyde composition containing iodine. C. BOGIN. U. S. 1,550,869, Aug. 25. Normal butyraldehyde is stabilized against oxidation by adding 0.01–0.25% of I, Cl, Br, hydroquinone, resorcinol or pyrogallol.

Styrolene and its homologs. NAUGATUCK CHEMICAL CO., I. OSTROMISLENSKY and M. G. SHEPARD. Brit. 232,909, April 24, 1924. Ethylbenzene and its homologs such as xylene, *o*-methylstyrene, *p*-methylstyrene, 1,3,5-dimethylstyrene or diethylbenzene are heated to 450 – 700° to split off H and form compds. of the type $\text{Ar}-\text{CH}=\text{CH}_2$. An app. for this purpose is described. Styrolene may be polymerized by heating for several hrs. at 180 – 200° with the optional addn. of an accelerator such as benzoyl peroxide. Homologs of benzene which have more than 2 C atoms in the side chain are heated to 500 – 700° . In treating cymene, CH_4 is split off and styrolene formed. Cinnamic acid and its homologs such as *o*- or *p*-methylcinnamic acids are heated to temps. of 250 – 650° (excluding, however, the temp. range of 300 – 500° within which anhydride of the acid and other products are formed). Styrolene obtained by these processes may be purified by shaking with alkali, distg. with steam and treating with CaCl_2 and finally with Na. Polymerization of styrolene or its homologs may be prevented by addn. of trinitrobenzene, quinone, mononitronaphthalene, TNT, PhNO_2 , dinitrobenzene, picramide "or other substances which act like mild oxidizing agents such as selenium." The nitro compds. retard polymerization at temps. below 170° but accelerate it above this temp.

Mono-alkylation of *m*-tolylenediamine. L. M. SHAFER. U. S. 1,550,749, Aug. 25. *m*-Tolylenediamine is warmed with dialkyl sulfate, without the addn. of an acid-binding material.

Observations on the mechanism of the tyrosine-tyrosinase reaction. R. A. GORTNER. *Proc. Soc. Exptl. Biol. Med.* **21**, 543–5 (1924).—Tyrosine oxidizes in the presence of tyrosinase and produces a change of colors from a deep rose-red to violet and finally a deposit of black pigment. Tyrosol, which has no amino group, did not oxidize beyond the rose-red color. An insol. tyrosinase was prepd. from the meal worm, *Tenebrio molitor*. Removal of the tyrosinase by filtration stopped the reaction. The red-black oxidation colors require the amino group and constitute a sep. reaction. C. V. B.

The non-uniformity of barley diastase. W. SYNIEWSKI. *Biochem. Z.* **158**, 87–120 (1925).—The non-uniformity in diastase action of enzyme preps. from different lots of barley is ascribable to differences in α -diastase and β -diastase, both of which contribute to the hydrolysis of starch. The products of the action of α -diastase on starch give a blue color with I. The products that give violet, red, brown or no color with I result from the action of β -diastase. Both the α - and β -diastases hydrolyze starch at the carbonyl or ether linkages of the starch mol. (cf. *Ann.* **324**, 212). F. A. CAJORI

Auxobody action. M. JACOBY and L. ROSENFELD. *Biochem. Z.* **158**, 334–6 (1925); cf. *C. A.* **19**, 1431.—Urease action in suitable concn. of EtOH (80%), though increased by such auxobodies as glycolcol, is diminished by KCN. F. A. CAJORI

The heat of combustion of pyrroacetic acid and its physiological significance.

H. BLASCHKO. *Biochem. Z.* **158**, 428-34(1925).—The heat of combustion of pyroracemic acid, detd. in a Berthelot bomb, was 279,140 cal. per mol., the heat of soln. 4566 cal. per mol., the heat of neutralization 11,400 cal. per mol. The heat of soln. of CH_3CHO was detd. as 4482 cal. The heat of reaction when pyroracemic acid is split by yeast carboxylase was detd.

F. A. CAJORI

The colloidal behavior of muscle proteins. I. The isoelectric point and conditions of stability of myogen. H. II. WEJER. *Biochem. Z.* **158**, 443-72(1925).—The isoelec. point of myogen of rabbit muscle is p_H 6.3, independently of the kind or concn. of the buffer present. Above a definite salt concn. the colloidal stability of myogen diminishes and pptn. occurs on the acid side of the isoelec. point, p_H 5.0. Anions cause a change in the elec. charge carried by the colloidal myogen as well as in its stability. The changes caused by anions are reversible and the myogen assumes its original condition when the anions are removed by washing. II. The isoelectric point and solubility of myosin. *Ibid* 473-90.—The point of max. pptn. of myosin by salts is at p_H 5.0. The isoelec. point of the muscle residue of rabbit muscle after removal of the press juice is p_H 5.1 to 5.2, indicating that there are different proteins in the residue from those in the press juice

Variations in phosphoric acid during glucolysis in the blood. GAETANO PIAZZA. *Arch. farm. sper.* **40**, 49-57(1925).—When freshly drawn blood is immersed in a water bath at 40° for 1 hr. the decrease in glucose is accompanied by an increase in inorg. P, which may amt. to as much as 0.94 mg. per 100 cc. This is attributed to hydrolysis of phosphatides. No relation was observed between the intensity of glucolysis and the amt. of inorg. P liberated. The importance of lactacidogen synthesis in the metabolism of carbohydrate is believed to have been overestimated.

A. W. DOX

Cozymase. VII. HANS V. EULER AND RAGNAR NILSSON. *Z. physiol. Chem.* **148**, 23-40(1925); cf. *C. A.* **19**, 81.—When glucose in the presence of phosphate is fermented at optimum acidity (p_H 6.0-6.5) the first 3rd of the total reaction occurs with const. velocity, then the fermentation curve flattens and the reaction proceeds at a considerably slower rate. Cozymase is put out of action in a reversible manner, presumably by combining reversibly with constituents of the dry yeast. In fresh yeast cozymase is bound entirely or for the most part to the protoplasm. Cozymase cannot be washed out from dried top yeasts but can be washed out completely or nearly so from dried bottom yeasts. Similar differences appear to exist with respect to the phosphate. Combined cozymase and free cozymase show different chem. behavior.

A. W. DOX

The kinetics of peptic action on fibrin. I. A. SMORODINTZEV AND A. N. ADOVA. *Z. physiol. Chem.* **149**, 179-83(1925).—With const. amts. of pepsin and fibrin the digestion of the substrate shows a linear relation, and in only 1 expt. with concd. artificial gastric juice does it follow the Schütz-Borissow law.

A. W. DOX

The maltase of barley and the specificity of the disaccharases. JESAJA LEIBOWITZ. *Z. physiol. Chem.* **149**, 184-94(1925).—The non-identity of barley maltase and yeast maltase is established by the fact that the former is inactive toward α -methylglucoside, does not catalyze the synthesis of α -ethylglucoside and does not hydrolyze β -methylmaltoside, while yeast ext. is active in all 3 instances. It must be assumed that yeast maltase attacks the glucoside portion and barley maltase the glucose portion of the maltose mol. Hence the 1st enzyme also hydrolyzes α -methylglucoside but the 2nd is unable to from the intermediate enzyme-substrate compd. and thus no cleavage can be effected. β -Methylmaltoside, although it contains the same 1,6- α -linkage as the free disaccharide, cannot be attacked by barley maltase because the glucose portion is essentially modified by the entrance of the Me group. This theory of localization of the

binding of disaccharases to definite parts of the substrate mol. is advanced in explanation of other instances of enzyme specificity and its modification by the introduction of substituent groupings. The stability optimum of barley maltase does not coincide with the activity optimum, the greatest stability being observed with citrate buffer at p_H 6.0.

A. W. DOX

The specificity of animal proteases. III. The specific actions of pancreatic trypsin and pancreatic erepsin. ERNST WALDSCHMIDT-LEITZ AND ANNA HARTENECK. *Z. physiol. Chem.* **149**, 203-20 (1925); cf. *C. A.* **19**, 3496.—Animal proteases may be classified into 4 groups: (1) peptidases, such as erepsin, which are sp. for simple di- and tripeptides, (2) enzymes of the type of non-activated trypsin, the action of which is demonstrated but has not yet been characterized by a strictly sp. substrate; (3) the activated trypsin type, e. g., trypsin + enterokinase, and (4) the pepsin type, the action of which is distinguishable from the others but cannot yet be definitely described. Among plant proteases, papain and its HCN compd. correspond to the 3rd and 2nd groups, resp. Numerous statements in the literature regarding the cleavage of protamines, histone and casein by erepsin are incorrect, and where such cleavage has been observed it must be attributed to contamination of the enzyme by trypsin. All of the dipeptides studied were hydrolyzed by erepsin but none of them was hydrolyzed by trypsin. The action of erepsin is limited to the simple peptides; peptic peptone, protamine, histone and proteins were not attacked by erepsin but were hydrolyzed by trypsin. Histone, protamine and peptone are hydrolyzed by non-activated trypsin, but for the cleavage of the high mol. proteins trypsin requires activation by enterokinase. Trypsin cannot, therefore, be considered as occurring in the pancreatic gland as an inactive zymogen. The activator functions merely as an accessory substance. The contention of Fischer and Aberhalden that the erepsin of the gland tissue and that of the secretion behave differently toward individual peptides could not be corroborated. Furthermore, the erepsin of the pancreas and that of the intestinal mucosa were found to be identical both qual. and quant. **IV. The spontaneous activation of trypsin.** *Ibid* 221-30.—By adsorption on $Al(OH)_3$ the activator can be removed from spontaneously activated trypsin and recovered in the elution. The exact detn. of activation performance of the substance formed by the gland is rendered difficult by the fact that the proportion of this substance to the tryptic enzyme cannot be controlled without a quant. sepn. and that its liberation from the gland material is accompanied by the formation of inhibitory substances. Its quant. characterization is possible only when it is sepd. in the form of its prokinase from the tryptic enzyme. After such sepn. by means of $Al(OH)_3$ adsorption the spontaneous activation of the trypsin in the mother liquor no longer occurs. The non-activated trypsin may then be activated by adding the elution. The formation of activator from its prokinase stage occurs spontaneously and is independent of the presence of trypsin. This activator functions under the same optimum conditions as the intestinal enterokinase and is identical with the latter. Whether its gradual formation from the prokinase stage is dependent on the erepsin which accompanies it in the sepn. from trypsin has not been detd. The identity of the pancreatic activator with enterokinase, as well as the presence of erepsin in both secretions, harmonizes with the view that the pancreatic gland is an evolutionary development from the intestinal mucosa.

A. W. DOX

The pectinase of *Sclerotinia cinerea*. G. W. MUHLEMAN. *Bot. Gaz.* **80**, 325-30 (1925).—*Sclerotinia cinerea* (the brown rot fungus) does not excrete pectinase in the culture media. The color of the felts of *Sclerotinia cinerea* is a good index of the activity of the pectinase solution which may be prepd.

B. H.

The cozymases of various fermentations. A. I. VIRTANEN. *Ber.* **58B**, 2441-5 (1925); cf. *C. A.* **18**, 3389; **19**, 2060.—Euler and Myrbäck's finding that insulin can replace the cozymase of lactic acid bacteria but not that of yeast has led to an investigation which has established the identity of muscle, yeast, lactic and propionic acid cozymases. Cozymase-free *Bacterium casei* ϵ was activated by yeast, muscle and propionic acid bacteria ext. and by insulin Wellcome in a 0.5 N phosphate soln. of p_H = 6.2 at 42°. The same insulin did not activate yeast. Since cozymase also catalyzes the zymophosphate formation it appears probable that the first stage of lactic and alc. fermentation is the same. There are, however, fermentation processes which do not require cozymase: the coli-aerogenes fermentation, the main end products of which are CO_2 , AcOH and succinic acid, and the succinic acid fermentation, which takes place concurrently with the propionic acid fermentation. The latter is catalyzed by cozymase and forms zymophosphate as may be observed from the amt. of free phosphate during the fermentation.

Labile albumin compounds. OSKAR LOEW. *Biol. Zentr.* **45**, 373-80(1925).—A discussion regarding the change from chemically labile compds. into relatively stable ones.

FRANCES KRASNOW

The regularity of the osmotic pressure effect of physiologically indifferent substances on unicellular animals. HANS FORTNER. *Biol. Zentr.* **45**, 417-45(1925).—The osmotic pressure effect of physiologically indifferent substances is dependent principally on the relative surface. The death of the cells is brought about by the withdrawal of water, and by the inhibition of the oxidative metabolism, together with the resulting autointoxication. The osmo-narcotic condition is a sequel to this autointoxication called forth by the insufficient oxidative metabolism. The oxidative metabolic end products cannot be excreted in sufficient quantity because of the withdrawal of water, hence paralysis sets in.

FRANCES KRASNOW

Radium influence on the colloidal state of protozoan cell contents. MARGARETE ZUELZER AND ERNST PHILIPP. *Biol. Zentr.* **45**, 557-72(1925).—Radium treatment brings about accelerated plasma flow. This effect is due to hydration of the protoplasmic colloids.

H. B. LEWIS

Studies on enzyme action. XXXIII. Lipase actions of extracts of the whole rat at different ages. K. G. FALK, H. M. NOYES AND K. SUGIURA. *J. Gen. Physiol.* **8**, 75-88(1925); cf. *C. A.* **19**, 1433.—The exts. were incubated 22 hrs. at 37-38° and the lipase activity was detd. by titration with 0.1 N NaOH soln. and phenolphthalein. The relative lipase actions were plotted on a scale on which Ph acetate or Me butyrate equaled 100 and the other esters as percentages of this action. Ten simple esters were used. Exts. of the embryos and young estrats gave curves resembling those given by Flexner-Jobling rat carcinoma (*C. A.* **18**, 1301); these curves changed with increasing age to a type characteristic of the adult rat and in the oldest rats appeared to revert to the embryonic type. The greatest increases in action with age were shown by the Me and Et butyrates; the smallest increase was shown by glyceryl triacetate. Expts. on protease activity, detd. by placing the exts. of whole rats of different ages with peptone, casein and gelatin at 38° for 22 hrs. and measuring the extent of the action by the formol titration method, did not parallel those for the lipase actions. This is because in the protease expts. the amt. but not the type of action is measured.

Is living protoplasm permeable to ions? W. J. V. OSTERHOUT. *J. Gen. Physiol.* **8**, 131-46(1925).—Expts. on the marine alga, *Valonia macrophysa*, show that almost no H₂S enters the cell sap except as undissociated mols.

C. H. R.

Theory of fermentation of amino acids. KANROKU KURONO. *J. Chem. Soc. Japan* **45**, 244-6(1925).—If the theory of alc. fermentation of amino acids of Neubauer and Fromherz (*C. A.* **5**, 1789) holds for all the amino acids, then the tertiary amino acids cannot be fermented by the yeast. Ehrlich (*Z. physiol. Chem.* **8**, 438(1908); cf. *C. A.* **2**, 1839) found, however, that *D*-isovaline is decompd. by the yeast, although no optically active BuOH could be isolated by fermentation of *DL*-isovaline. K. prepd. another tertiary α -amino acid, and tested N. and F.'s theory. Ten g. of *DL*-methyl-*n*-propyl- α -amino acetic acid, 300 g. cane sugar, 2250 cc. H₂O, and 150 g. yeast (No. 12) were incubated at 20-5° for 2 days. At the end of the incubation, K. isolated 2 g. of *DL*-methyl-*n*-propyl- α -aminoacetic acid, 0.5 g. of *L*-form ($[\alpha]_D^{20} = -8.37^\circ$), and the corresponding secondary alc., methylpropylcarbinol. The conclusion is that N. and F.'s scheme in assuming α -ketonic acid as an intermediate product of the amino acid fermentation does not hold for all the amino acids. The fermentation of this new leucine by

the yeast must probably go according to $\text{MePrC}(\text{NH}_2)\text{CO}_2\text{H} \xrightarrow{\text{NH}_2} \text{MePrCO} + \text{NH}_3 + \text{CO}_2 \xrightarrow{\text{H}_2} \text{MePrCHOH}$. The detailed method of identification of the various products of the fermentation and their chem. and phys. chem. characteristics are given. S. T.

The affinity of saccharase for different sugars. IV. KARL JOSEPHSON. *Arkiv. Kemi Mineral. Geol.* 9, No. 20, 1-5(1925) (in German); cf. C. A. 18, 2717.—No new work is reported (cf. C. A. 18, 2528). M. A. YOUTZ

The constitution of proteins (TROENSEGAARD) 10. Influence of alkali in hemolysis experiments on drug extracts (KARSMARK, KOFLER) 17.

B--METHODS AND APPARATUS

STANLEY R. BENEDICT

Chamber with thermostatic control and rotating table for plant cultures. S. F. TRELEASE. *Bull. Torrey Bot. Club* 52, 389-95(1925).—The chamber is $57 \times 34 \times 40$ inches, and can be kept at any temp. between 10° and 35° with a variation of 0.5° . It is equipped with a rotating table and thermostatic control made up from standard commercial appliances. JOSEPH S. CALDWELL

The groups responsible for the nucleal reaction and nucleal staining. II. Also remarks on the preparation of hydroxymethylfurfural. R. FEULGEN AND K. IMHÄUSER. *Z. physiol. Chem.* 148, 1-16(1925); cf. C. A. 18, 3069.—The contention of Steudel and Peiser (C. A. 19, 80) that the nucleal reaction is due to hydroxymethylfurfural (I) is refuted on the following grounds: (1) The color produced by I and fuchsin- SO_2 has a reddish tint resembling fuchsin soln. while that obtained in the nucleal reaction is bluish and resembles crystal violet soln. The 2 cannot be matched in a colorimeter. (2) The color produced by hydrolyzed thymonucleic acid and fuchsin- SO_2 is stable while the color from I and fuchsin- SO_2 rapidly fades and disappears completely. (3) The substance responsible for the nucleal reaction is extremely sensitive to heat while I is much more stable. (4) $\text{PhNH}_2 \cdot \text{AcOH}$ gives an orange color with I and a reddish color with furfural. At a diln. of 0.5% I reacts intensely with $\text{PhNH}_2 \cdot \text{AcOH}$ but not with fuchsin- SO_2 while the reverse is true of partially hydrolyzed thymonucleic acid. (5) I is sol. in EtOAc while the substance responsible for the nucleal reaction is insol. (6) The odor of bread noted by Steudel and Peiser in the hydrolysis of thymonucleic acid indicates that their hydrolysis was carried too far. When the reaction is properly performed no such odor can be detected. (7) An intense nucleal reaction is obtained with 0.5 mg of thymonucleic acid while the color from the same amt of I is subliminal. Sucrose, which yields 10% of I, is 10,000 times less sensitive to the nucleal reaction than thymonucleic acid under the same conditions. The prepn of I by Middendorp's method (C. A. 13, 2344) can be facilitated by collecting separately the few crystals which form in the beginning of the distn. and using these to seed the remainder of the distillate. A. W. DOX

Preparation of standards for the colorimetric determination of pepsin. I. A. SMORODINTZEV AND A. N. ADOVA. *Z. physiol. Chem.* 149, 173-8(1925).—For the colorimetric detn. of pepsin by the fibrin-diphenylrosaniline method it is important that the stained fibrin and the colorimetric standard be prepd. from the same fibrin and the same dye. The addn. of an equal vol. of glycerol prevents the development of turbidity and a standard thus prepd. undergoes no change when kept 8 months. At an acidity of 0.1% HCl the fibrin swells rapidly and is readily digested by very dil. enzyme. It is recommended that enzyme dilns. of 200-1000 be used and that color comparisons be made every 5 min. A. W. DOX

Improved micromethods. I. FRIEDRICH HOLTZ. *Klin. Wochschr.* 4, 1685-7(1925).—Essentially a detailed description of an ultra balance manufactured by the Paul Bunge Precision Balance Co., Hamburg. It is sensitive to 0.0000001 g. and has a capacity of 50 g. MILTON HANKE

Exact dosage of inhaled substances by means of an electro filter. HARRY SCHAFER. *Klin. Wochschr.* 4, 1765-7(1925). MILTON HANKE

Titration, estimation of the hydrogen-ion concentration and "titration of the indicator" in gastric juice. HEINZ KALK AND BERNHARD KUGELMANN. *Klin. Wochschr.* 4, 1806-10(1925).—"Titration of the indicator" (Sahli, cf. C. A. 19, 2680) and the old method of titration with dimethylaminoazobenzene give identical results with a test meal free from protein such as the alc. test meal and the Ewald-Boas meal. The old method is not an accurate index of the acidity when the gastric contents contain protein or lactic acid. In such cases the method of Sahli or actual p_H detns. by the indicator method will have to be resorted to. MILTON HANKE

A microchemical histological method for the differentiation of tissue by iron salt formation. ERWIN CHRISTELLER AND KARL KAISER. *Klin. Wochschr.* 4, 2193-4 (1925).—The freshly isolated tissue is immersed in an aq. soln. of an iron salt for 24 hrs. A number of ferric and ferrous salts were tried. The tissue is then either frozen and sectioned, or fixed in formalin and then frozen and sectioned. The sections are washed with water, immersed in a soln. of $K_4Fe(CN)_6$, washed and mounted. Connective tissue does not bind iron; it is almost colorless. The nuclei of all cells are pale blue, blood cells are dull green and serum is light green. The protoplasm of all epithelial cells is dark blue. Carcinoma cells are most intensely colored. Muscle fibers, both smooth and striated, are colored brilliantly blue. The differentiation can be sharpened by counterstaining with eosin, orange G, alum carmin or phenosafranin. MILTON HANKE

Delicate color reaction for the presence of vitamin A. OTTO ROSENHEIM AND J. C. DRUMMOND. *Biochem. J.* 19, 753-6 (1925).— $AsCl_3$ gives with cod-liver oil a brilliant ultramarine-blue color reaction. Like the H_2SO_4 test (*C. A.* 14, 2208; 16, 3550) it is characteristic for vitamin A. It has the advantage that the color persists sufficiently to allow a colorimetric comparison with a suitable standard. The reaction is carried out by adding 1 cc. of pure $AsCl_3$ to one drop of cod-liver oil, and shaking the test-tube at once. The oil dissolves immediately, forming a clear blue soln., and in the course of a few seconds assumes a purple tint and gradually fades. The reaction is characterized by a well-defined absorption band extending from λ 550 to 590. Under the above conditions, the band persists for about 5 mins. A 1% soln. (in light petroleum) of a highly growth-promoting Newfoundland cod-liver oil reacted intensely with 1 cc. $AsCl_3$ in amts. of 0.05 cc. (= 0.5 mg.) oil. The oil was saponified and the unsaponifiable portion freed from cholesterol by means of digitonin. The cholesterol-free fraction now gave the reaction in a diln. of 1:2,000,000. Like vitamin A, the chromogenic substance resists saponification and is coned. in the cholesterol-free unsaponifiable fraction of cod-liver oil; like vitamin A, the chromogenic substance can be destroyed when a current of air is passed through the oil at 100° (after 30 minutes' aeration the reaction is diminished and is no longer given after 60 min.). Tests on more than 30 oils and fats show complete agreement between color intensity and growth-promoting activity. The color reaction makes it possible to differentiate vitamin A from the antirachitic substance, since cholesterol, which was made highly antirachitic by irradiation with ultra-violet light, does not give the $AsCl_3$ test. Both vitamin A and the antirachitic substance diffuse through a rubber membrane. A number of substances which share with $AsCl_3$ the property of imparting a red color to cholesterol (such as Me_2SO_4 , Cl_3CO_2H , $AcCl$ and $BzCl$ —the last two only in the presence of $ZnCl_2$) also give the blue color with substances contg. vitamin A. Is vitamin A, therefore, related to the sterols? Vitamin A is also linked to the lipochromes in that these substances, particularly carotin (dissolved in light petroleum or chloroform), give a slate-blue color with $AsCl_3$, which is distinguished from cod-liver oil by being permanent. "In view of the possible relationship between sterols and lipochromes in their general association with vitamin A in plant tissues (Coward, *C. A.* 17, 2304), it is suggested that the $AsCl_3$ reaction is concerned with a substance derived from these types of synthetic plant products under the influence of sunlight." A suitable color standard for the $AsCl_3$ reaction is a mixt. of 100-cc. crystal violet soln. (1:10,000) with 50 cc. methylene blue soln. of the same strength (both in alcohol). Under the conditions chosen, the color produced by 20 mg. of a highly active Newfoundland oil (= 1 drop from a pointed glass rod of 3 mm. diameter) with 1 cc. $AsCl_3$ matches the standard dye soln. dild. in the proportion of 3:2. After prepg. a set of suitably dild. standard solns. in a test-tube of uniform diam., we found, after a little experience, no difficulty in ranging all the oils so far examd. in a series which agreed with their growth-promoting activity." BENJAMIN HARROW

Method for the estimation of iodine in the thyroid gland. F. A. PICKWORTH. *Biochem. J.* 19, 768-72 (1925). The method depends upon the destruction of org. matter by fusion with alkali and oxidation of the resulting iodide to iodate with permanganate soln.; excess of the latter is removed with animal charcoal, and after adding iodide, the liberated I is titrated with thiosulfate. *Method*—Weigh 0.2 g. finely powd. dry thyroid and introduce into a Ni crucible of 150 cc. capacity. Add 10 cc. 50% NaOH and mix by rotating the crucible; cover with a lid having a hole $1/8$ " in the center and heat slowly till the water is evapd. Next heat the crucible in an oven considerably below red heat but hot enough to give a clear fusion product in about 1 hr. Then heat over a large free flame protected so that the crucible and the lid can be rapidly raised to a dull red heat, which is maintained $1/2$ -1 min. Allow the crucible to cool, add 70 cc. water and place on warm plate for about 1 hr., when gentle stirring will bring the whole into soln., transfer to a 250 cc. Erlenmeyer flask and add 3 drops of 10% Na_2SO_3 soln.; acidify

with 50% H_2SO_4 from a buret; add 3 cc. in excess, cool and add 5 cc. approx. 0.1 N permanganate. After 3 min. add a suspension of charcoal; when decolorization is complete, filter and wash with a little water. Add a crystal of KI and titrate immediately with freshly prepd. 0.01 N thiosulfate. One cc. thiosulfate $\times 85$ gives the mg. of I in 100 g. of dried gland when 0.25 g. is taken for analysis. BENJAMIN HARROW

The differential estimation of fat in feces. G. A. HARRISON. *Brit. J. Exptl. Path.* **6**, 139-461 (1925).—Gross errors in the percentage of split fat in dried feces may result from hydrolysis of the soaps by acid alc. The mean mol. wt. of the fatty acids from 50 to 100 samples of pathological feces was 268. The factor 1 cc. of 0.1 N soda corresponds to 0.0268 g.; fatty acids are, therefore, suggested for calcg. the quantity of split fat. By using continuous extn. in a Soxhlet app. or the method of Holt, Courtney and Fales (*C. A.* **13**, 965), in duplicate estns. of the total fat, the av. variation from the means was $\pm 2\%$ and of the split fat $\pm 3\%$. HARRIET F. HOLMES

A useful preservative for whole blood. A. H. BAKER. *Brit. J. Exptl. Path.* **6**, 201-2 (1925).—Fowl blood will travel safely for several days through the post, and permit a satisfactory agglutination test on its arrival if the boric acid content of the tube be between $\frac{1}{100}$ and $\frac{1}{500}$. HARRIET F. HOLMES

A buffered solution for perfusion of isolated organs. R. N. CHOPRA AND SUDHAMOY. *Indian J. Med. Research* **13**, 7-10 (1925).—Proof is given to show that Fleisch's soln. is better for perfusion than either the Ringer or Tyrode soln. F. K.

Studies of acidosis. XXI. The colorimetric determination of the p_{H} of urine. A. BAIRD HASTINGS, JULIUS SENDROY, JR. AND WM. ROBSON. *J. Biol. Chem.* **65**, 381-92 (1925), cf. *C. A.* **19**, 86.—The method employs bicolor standards of bromocresol green, bromocresol purple and phenol red, covering a p_{H} range of 4.0 to 8.2, based on the assumption that the color of an indicator soln. is due to a mixt. of the acid and alk. forms of the indicator. The accuracy with all precautions employed is only 0.1 p_{H} as compared with 0.02 p_{H} of blood detns. (Hastings and Sendroy, *C. A.* **19**, 86). The accuracy of the colorimetric method has been increased by preventing loss of CO_2 and by allowing for the error introduced by the diln. of the urine. A. P. LOTHROP

A more specific reagent for the determination of sugar in urine. J. B. SUMNER. *J. Biol. Chem.* **65**, 393-5 (1925); cf. *C. A.* **19**, 1146.—A new reagent is described which appears to be almost completely specific for reducing sugars and figures obtained by its use are over 40% lower than those given by the previously described reagent and lower than those given by the Benedict-Osterberg method even after charcoal is used. *Method* Pipet 1 cc. of urine (dild. if necessary) into a Folin-Wu sugar tube and add 3 cc. of reagent. Mix and heat 5 min. in boiling water. Cool 3 min. in running water, dil. to 25 cc., mix, and compare in a colorimeter (within 30 min.) with a standard prepd. with 1, 0.5, or 0.25 mg. of glucose, according to the concn. of sugar in the urine. Concd. urines contg. over 0.18% or dil. urines contg. over 0.12% of sugar can be considered abnormal. The method is entirely satisfactory for the estn. of sugar both in normal and in diabetic urine. *Reagent*.—Add 22 cc. of 10% NaOH to 10 g. of crystd. PhOH, dissolve in a little H_2O and dil. to 100 cc. Add 6.9 g. of NaHSO_3 to 69 cc. of the alk. PhOH soln. Now add a soln. contg. 300 cc. of 4.5% NaOH, 255 g. of Rochelle salt, and 880 cc. of 1% dinitrosalicylic acid. Mix and keep tightly stoppered in well-filled bottles; the reagent will keep at least a month. A. P. LOTHROP

The sugar content of blood. B. K. HARNED. *J. Biol. Chem.* **65**, 555-60 (1925). When the proteins of blood are pptd. by acid $\text{Hg}(\text{NO}_3)_2$ the filtrate contains N only in the form of nitrate and is thus free from many, if not all, of the non-sugar blood components which interfere with the methods of detg. blood sugar. This method of pptn. has been employed in an endeavor to det. the absolute concn. of glucose in the blood. When the Folin-Wu method is applied to such filtrates the values obtained averaged 17-25% lower than those usually obtained and are in accord with those given by the new Benedict method (*C. A.* **19**, 2352) for blood sugar. The procedure is not recommended as a routine method because of the laborious and exacting technic involved. A. P. LOTHROP

A method for the determination of total sulfates in tissues. W. DENIS AND STELLA LECHE. *J. Biol. Chem.* **65**, 561-3 (1925).—Place 10 g. of finely divided tissue in a 25 \times 200 mm. Pyrex test-tube and add 50 cc. of N HCl. Cover the tube with a small watch glass held in place by a square of tin foil and heat in a chem. autoclave at 200° for 1 hr. or in a bacteriological autoclave at 150° for 2 hrs. Transfer quant. to a 100 cc. volumetric flask and fill to the mark. Mix thoroughly, transfer to two 50 cc. centrifuge tubes and centrifuge for 5 min. Filter by suction through a Gooch crucible provided with a thin asbestos mat. Transfer 40 cc. of the filtrate to a 250 cc. beaker and ppt. the sulfates by the addn. of 10 cc. of 5% BaCl_2 soln., added drop by drop from a buret. Heat

to boiling, allow to stand overnight and filter through a tared Gooch crucible. Wash, dry and ignite the BaSO_4 in the usual manner. No cystine S is transformed into SO_4 by this procedure and the results apparently represent only the preformed sulfates present in the tissue. The total sulfate contents of certain dog and beef tissues are as follows in mg. per 10 g. of tissue: dog: lung 1.0, liver 20.7 (av.), muscle 0.87, kidney 4.39, heart 1.58; beef: liver 2.3, muscle trace, kidney 3.8, brain, 11.1. A. P. L.

The colorimetric p_H test of water and unbuffered solutions. H. T. STERN. *J. Biol. Chem.* 65, 677-81(1925).—A bromothymol soln. for testing unbuffered solns may be satisfactorily prepd. by adding alkali until a pure dark green color is obtained but the soln. is not stable and shows a red translucence after about 2 months even though kept in paraffined Nonsol flasks. p -Nitrophenol is a more reliable indicator and the soln. that will show a neutral reaction in pure H_2O is prepd. as follows: Titrate 5.0 cc. of a 0.3% soln. in pure H_2O with 0.1 N KOH with Biilmann's quinhydrone electrode as an indicator of the C_H . 0.33 to 0.34 cc. is usually necessary to bring the soln. to p_H 7, the beginning p. d. corresponding to p_H 4.9. The amt. of alkali necessary for the whole vol. of soln. is calcd. from the figures obtained. The amt. of alkali used corresponds to approx. $\frac{1}{3}$ mol. of the indicator soln. the dye powder (being assumed to be 100% pure). CO_2 from the atm. does not seem to affect the colorimetric p_H test. A. P. LOTHROP

A micro-method for the determination of base in blood and serum and other biological materials. WM. C. STADIE AND EFFIE C. ROSS. *J. Biol. Chem.* 65, 735-54 (1925). —A micro-method for the detn. of total base, reliable to 1%, in whole blood, cells, serum and other biological materials is described in which the bases are converted into sulfate, pptd. by standard benzidine-HCl, and the benzidine sulfate is detd. by titration of the excess of benzidine-HCl. The advantage of indirect titration instead of direct titration of the benzidine ppt. lies in the elimination of quant. transfer of a small ppt., of washing the ppt. with Me_2CO , of the transfer of the washed ppt. back into a titrating vessel, of hot titration of the ppt., and of a variable titration blank of filter paper. The method reduces considerably the time and labor necessary for analysis. It is necessary to remove phosphates from biological materials, such as urine, gastric contents, feces, etc., which contain excessive amts. and this may easily be done by pptg. the phosphate as FePO_4 . The original must be consulted for the analytical details. A. P. L.

Method for detecting and estimating bile acids in the urine. E. C. MEYER. *Deut. Arch. klin. Med.* 147, 274-82(1925).—The method involves a detn. of the amt. of NaCl required to produce a certain surface tension of the soln. under examn. An acid soln. has a lower surface tension than a neutral one. The presence of bile acids in the urine. *Ibid* 282-6.—Bile acids are found in almost every urine contg. urobilin, but not always where there is bilirubin. F. B. SEIBERT

C—BACTERIOLOGY

A. K. BALLS

The source of energy of the sulfur bacteria. I. B. BECKING. *Proc. Soc. Exptl. Biol. Med.* 22, 127-9(1924).—Bacteria which deposit S inside or outside the cell are supposed to derive this substance and also their energy from oxidation of H_2S . The organisms occur in waters of p_H 7.6-8.6; this medium has 50-100 times more HS ions than undissociated H_2S . H_2S has a lower energy level than S and is unfit as a source of energy unless a compensating oxidation of H_2 would occur; this is improbable in the low O_2 tension of the black mud in which the bacteria live. Probably the HS or the S ion is the source of energy. C. V. B.

Changes in the virulence and growth characteristics of *Bacterium leprosepticum* following alterations in oxygen tension. L. T. WEBSTER. *Proc. Soc. Exptl. Biol. Med.* 22, 139-41(1924); cf. *C. A.* 19, 1583.—*Bacterium leprosepticum* is so delicately adjusted in its O_2 requirements that it fails to multiply freely or to maintain certain characteristics associated with its virulence unless available O_2 is mech. limited, or the O_2 effect is minimized by the presence of peroxidase. C. V. B.

The influence of the hydrogen-ion concentration on bacteriological processes. F. C. GERRETSEN. *Verslag. Onderzoek. Rijkslandbouwproufst. 30*, 1-44(1925).—G developed a colorimeter, known as the "bioclorimeter" on the same principal as that given by Gillespie (*C. A.* 15, 3650). Centrifuged soil exts. gave results which were comparable with the electrometric detns., while filtering the soil exts. or percolating according to Parker gave unreliable results. Nitrite formation in soln. took place between the p_H range 5.75 and 9.65 with a sharp optimum between 7.5 and 8.2. The equilibria of the nutrient salts at varying H-ion concns. also influenced the nitrite formation.

Nitrate formation took place between p_H 5.4 and p_H 10 with an optimum between 8.1 and 9.2. Formation of nitrite and nitrate was carried out in the same culture medium so long as the p_H remained low even if $(NH_4)_2SO_4$ was present in the solns. Soil suspensions adjusted to various H-ion concns. with definite mixts. of Na_2HPO_4 and HPO_4 and contg. $(NH_4)_2SO_4$ showed that at p_H values 3.7 and 4.0 there was no nitrite or nitrate formation—at p_H values from 5.7 to 7.0 nitrate only was present—indicating the rapid oxidation of nitrite. At p_H values around 8.9 and 9.0 the processes seemed to stand still. It is suggested that the max. quantity of $(NH_4)_2SO_4$ which a soil is able to tolerate at a given time is of practical significance. Soil suspensions, inoculated with active cultures of nitrifying organisms and contg. calcd. quantities of $(NH_4)_2SO_4$, gave results which showed a satisfactory agreement between the buffering power as calcd. from the resulting nitrification and that from titration curves. The buffering power of the soil was found to be a limiting factor in nitrate formation. Bacterial nos. were found to exert little or no influence; however, the moisture content of the soil influenced the rate of nitrite formation and the rate of nitrite disappearance. The soln. of phosphates by the nitrification process depends on the buffer content of the soil. R. M. BARNETTE

Bacterial fermentation, particularly in the coli-typhosus group. W. C. DE GRAAFF AND A. J. LE FÈVRE. *Biochem. Z.* 155, 313–32(1925).—Neuberg's method of fixation with Na sulfite has been extensively employed in an investigation of the production of AcH during the fermentation of a large no. of sugars and polyhydric alcs. by various members of this group of bacteria. AcH is invariably found wherever gas or acid formation takes place. Many of the simpler sugars and related compds., *e. g.*, glyceraldehyde, glycerol, glyceric acid, dihydroxyacetone, pyruvic acid, ethylene glycol, are fermented by certain of the colon organisms with intermediate production of AcH. Support is given to Neuberg's view as to the importance of pyruvic acid as an intermediate substance during bacterial fermentation. The basal medium employed was peptone water contg. Na sulfite, with $CaCO_3$ in suspension. The fermentation of glycol, pyruvic acid, and glycerol by *Bacillus coli* was followed quantitatively and a C balance sheet prep'd. CO_2 , AcOH and H were the main products; only with glycerol were appreciable quantities of succinic and lactic acids formed. The succinic acid is probably formed from pyruvic acid. B. C. A.

Antiseptic action of α -hop-bitter acid and its decomposition products on micro-organisms. W. WINDISCH, P. KOLBACH AND E. RATHKE. *Wochschr. Brau.* 41, 175–220 (1924).—The α -acid (humulone) was ext'd. from lupulin (hop meal) with ether, the soln. evap'd., and the residue dissolved in 80% MeOH to free it from resins. The acid was det'd. by pptn. as Pb salt, which was decomposed with K_2S , and the PbS was collected and weighed. The α - and γ -resins were obtained by decompn. of the α -acid. A series of expts. was made on the influence of H-ion concn. on the decompn. With p_H about 8, the α -acid was completely destroyed after boiling for 8 hrs.; with p_H 5 only half the amt. was destroyed in the same time, the amt. being influenced to a small extent by the nature of the buffer substance employed. The proportion of α - to γ -resin so produced varied from 9:1 under conditions of rapid decompn., to about 5:1 when the decompn. proceeded more slowly. The mixts. of α -acid and α - and γ -resins obtained in these expts. were used for the toxicity tests. 190 cc. of malt ext. were inoculated with 10 cc. of a soln. contg. a culture of *B. delbrücki*, and a known weight of hop ext. dissolved in 2 cc. of 95% alc. was added. After incubating for 4 hrs. at 38–42°, 20 cc. were withdrawn, sterilized, filtered and titrated with 0.1 N NaOH. Further samples were taken at intervals and the increase of acidity was measured. The antiseptic powers of the acid and resins were expressed as percentage increase of acidity of the soln. The results obtained show that the toxic action is proportional to the amt. of substance present up to 6 mg. of hop ext. per 200 cc. A break, however, is shown at about 1.5 mg. which is probably due to colloidal influences. The α -acid showed the max. antiseptic power, an increase of 4% acidity being obtained with 6 mg. per 200 cc., compared with an increase of 40% in the control expt. The toxic power of the α -acid was $1\frac{1}{2}$ –2 times greater than that of the α -resin, while the γ -resin had a toxic power only $\frac{2}{3}$ that of the α -acid. Mixts. of acid and resins had a toxic power equal to the sum of the toxic powers of the constituents. B. C. A.

Fermentation and oxidation of zymohexose in yeast. I. HANS V. EULER AND RAGNAR NILSSON. *Chem. Zelle u. Gewebe* 12, 238–42(1925).—The rate of fermentation of glucose by brewer's yeast measured by the glucose concn. of the fermenting mixt. was not influenced by bubbling air or N through the soln. even in the presence of $FeSO_4$. The addn. of H_2O_2 diminished the rate of glucose destruction, probably due to the poisoning action. A count of the yeast cells showed that the number remained const. in each case. H. J. DEUEL, JR.

The significance of p_H in bacteriology. I. M. KOLTHOFF. *Tijdschr. vergel. Geneeskunde* 11, 268-77(1925); cf. *C. A.* 12, 2343; 13, 1481, 2895; 16, 946.—Results of various investigators show that the growth of bacteria in cultures is brought to a standstill not by the H^+ but by the undissociated acids formed by the growing bacteria. A titrimetric detn. would therefore be of the same value as the p_H detn. The problem is complicated by the simultaneous formation of several acids by the same bacteria and the dependence of this formation on the growth conditions. An investigation, of the influence of undissociated acids is indispensable.

MARY JACOBSEN

Solubility of tubercle bacilli in cod-liver oil. M. D. HORST. *Tijdschr. vergel. Geneeskunde* 11, 320-7(1925).—Landsberg's expts. were repeated. The tubercle bacillus is not easily sol. either in the common yellow, or in the purified oil. The changes observed in the oil are probably due mainly to the influence of air and heat. Mutual action between bacilli and oil is evidenced by the shrinking of the former and a decrease in I value and increase in acid value of oil heated with bacilli in an H atmosphere. Heating with H alone also seems to affect the constants of the oil. The crude oil is less affected.

MARY JACOBSEN

Insulin and microorganisms. L. B. WINTER AND W. SMITH. *Proc. Physiol. Soc., J. Physiol.* 60, v. (1925).—Microorganisms (*B. coli* or yeast) that were shown to contain an insulin-like substance, lost this property after cultivation for several months in pure culture. With *B. coli* activity was regained after lactose replaced glucose in the nutrient soln.

J. F. LYMAN

A new agar-splitting bacterium. K. Aoi. *Centr. Bakt. Parasitenk., II Abt.* 63, 30-2(1925).—The organism was isolated from stable manure and its cultural characteristics are described.

JOHN T. MYERS

The optimum for growth and diastase production of *Aspergillus oryzae*. Y. NISHIWAKI. *Centr. Bakt. Parasitenk., II Abt.* 63, 102-6(1925).—The optimum temp. is 35.5° to 34.5°, the min. 7° to 9°, and the max. 45° to 47°.

JOHN T. MYERS

A thermophilic sulfate-reducing bacterium. L. ELION. *Centr. Bakt. Parasitenk., II Abt.* 63, 58-67(1925).—*Vibrio thermodesulfuricans* is Gram negative, grows in an inorg. medium at 55°, and forms considerable amts. of H_2S .

JOHN T. MYERS

A spirillum which can bind free nitrogen. M. W. BEIJERINCK. *Centr. Bakt. Parasitenk., II Abt.* 63, 353-9(1925).—*Sp. lipoferrum* seems able to bind free N but more work is promised.

JOHN T. MYERS

Hydrogen sulfide production by anaerobic spore-bearing bacteria. M. C. KAHN. *J. Bact.* 10, 439-47(1925).—No essential correlation is observed between the native protein-digesting ability and the H_2S -producing properties of the organisms.

JOHN T. MYERS

Indole studies. W. I. KULP. *J. Bact.* 10, 459-71(1925).—The Böhme-Ehrlich, Goré and Gnezda tests for indole are apparently satisfactory. A good medium for indole production by bacteria should contain free tryptophan. Indole negative organisms do not use indole, nor can they be induced to produce it by continued subculture in a tryptophan medium. Satisfactory p_H for growth of a bacterial species is also favorable for indole production by that species. Indole production is delayed in proportion to the amt. of carbohydrate present, but media contg. small quantities can be used if sufficient buffer is added.

JOHN T. MYERS

The conditions governing the appearance of taches vierges in bacteriophage activity. F. M. BURNET. *J. Path. Bact.* 28, 419-27(1925).—The fundamental differences between the activities of phages seem to lie in the readiness and directness with which the phage can be adsorbed to the specific entity in the bacillus which it is designed to stimulate. Any bacillus in which a direct adsorption of lytic particles occurs becomes a center for lysis. When a lytic particle remains unattached to a sensitive bacillus in a colloid-contg. medium it is progressively weakened, probably by accretion of colloid mols. around it. A strong phage can retain stimulating powers along with a considerable accretion of colloid mols.

JOHN T. MYERS

Acquired tolerance of gonococci in culture to mercurochrome-220 sol. C. C. SÆLHOF. *J. Am. Med. Assoc.* 84, 1267-8(1925).—The lethal dose of mercurochrome-220 sol. for the strains of gonococcus used increased after cultivation of the gonococcus on a medium contg. mercurochrome. Consequently, acquired tolerance of the gonococcus for mercurochrome was demonstrated in the test tube.

L. W. RIGGS

Viability of typhoid bacilli in shell oysters. E. O. JORDAN. *J. Am. Med. Assoc.* 84, 1402-3(1925).—Shell oysters artificially contaminated with typhoid bacilli (by floating for 1 hr. in sea water to which typhoid bacilli had been added) were then placed at ice box temp. (5 to 8°) and found to contain living typhoid bacilli for as long as 24 days. There was no evidence of multiplication, but after the first few days a diminu-

tion in the no. of bacilli was apparent. Of the 3 strains used, the survival period was 21, 22 and 24 days, resp. **Viability of *Bacillus typhosus* in oysters during storage.** F. O. TONNEY AND J. L. WHIRRE. *Ibid* 1403-6.--Shucked oysters were contaminated with typhoid bacilli and stored at 37°, 21° and 7.2°. In the oyster fluid, *B. typhosus* survived in considerable nos. for 1, 4 and 22 days, resp. Living shell oysters were contaminated with large nos. of typhoid bacilli and stored at 21° and at 7.2°. At the former temp., *B. typhosus* survived in the fluid within the shells for 8 days; at the latter temp., which is the ordinary icing temp. of the trade, the organisms survived for 60 days. The exterior of the shells of oysters exposed for 48 hrs. to a 4% soln. of sea salt, contg. large nos. of *B. typhosus*, showed the presence of typhoid bacilli on the 23rd day after storage at 7.2°. Shell oysters with the valves open, moisture evapd. and meat rotten contained typhoid bacilli. In general the temp. best suited for the preservation of oysters tends to prolong the life of the typhoid bacilli in them. L. W. R.

The biogens, inactive mother-substances of the two bioses. EDNA V. EASTCOTT. *Trans. Roy. Soc. Can., Sec. III* [3] 19, 21-4(1925); cf. C. A. 18, 1689.--The increased production of bios I and bios II from infusions of white baking flour and malt combings, resp., when permitted to stand for a time at 25° and 55° is attributed to the presence of inactive substaces called "biogens" from which the corresponding bios is formed. Warming with alkalis converts the biogens into bioses while acids, alcs. or heating dry converts bios II into biogen II. Both biogens are pptd. by lime or baryta in alc. After sepg. of the biogens, bios II was found to be very stable, resisting the action of Fehling soln., neutral KMnO₄, I, H₂O₂, warm concd. H₂SO₄, Ac₂O and AcCl. The biogens have not yet been isolated. Postulating the existence of biogenases explains the irregular behavior of the bioses observed in the production of yeast under controlled exptl. conditions. J. W. SHIPLEY

The reproduction of yeast in solutions in which no bios has been added. DOROTHY WHITEMAN. *Trans. Roy. Soc. Can., Sec. III* [3] 19, 24-5(1926); cf. C. A. 17, 1495.--Reproduction of yeast to a limited extent takes place without bios and also without salts and even without sugar. It is assumed that a certain quantity of bios exists in the yeast cell itself. J. W. SHIPLEY

5-Methylcytosine in tuberculinic acid (JOHNSON, COGILL) 10. Correlation of the sulfite reduction test with other tests in the bacterial examination of water (WILSON, BLAIR) 14.

Absorption of salts by vegetable cells; epictesis and selection. L. LAPICQUE. *Bull. soc. chim. biol.* 7, 621-37(1925).--A theoretical discussion. A. T. CAMERON

The selective absorption of potassium by plants. G. ANDRÉ AND E. DEMOUSSY. *Bull. soc. chim. biol.* 7, 806-10(1925).--See C. A. 19, 2360. A. T. CAMERON

Rhamnucoside, new glucoside, generator of Chinese green, obtained from the bark and stem of the purging buckthorn (*Rhamnus cathartica* L.). The products of enzymic hydrolysis of rhamnucoside: primeverose and rhamnicogenol. The distribution of rhamnucoside in the genus *Rhamnus*. M. BRIDEL AND C. CHARAUX. *Bull. soc. chim. biol.* 7, 811-21; 822-30(1925).--See C. A. 19, 2107. A. T. CAMERON

Plant reproductive cells. II. The chemical constituents of the spores of *Aspidium filix mas*. ALEXANDER KIESEL. *Z. physiol. Chem.* 149, 231-58(1925).--Successive extrns. of the spores of the fern with Et₂O and EtOH gave 3.95% cerotic acid and 17.06% of oil. Another lot of spores collected in warm summer weather yielded 24.7% of oil. The cerotic acid, which was identical with that from beeswax, seems to occur as a protein complex, since a complete extrn. cannot be effected unless the material is boiled with EtOH. The oil gave the following const.: acid no. 48, ester no. 187.3, sapon. no. 192.1, I no. 104, Ac no. 6.8, insol. fatty acids 88%. The acids consisted mainly of oleic with a small amt. of linoleic. Sapon. of the oil gave 0.87% volatile fatty acid, 8.95% glycerol, 4.92% cholesterol, 0.61% choline, 1.58% H₃PO₄, 0.54% sugar. Less than half of the oil was in the form of triglycerides. The spores contained 1.51% total N, 1.39 protein N (8.69% protein) and 3.69% ash on the basis of dry wt. Direct detn. of sucrose showed 1.77%. Hydrolysis of the extd. residue with 33% H₂SO₄ gave azalaic acid, tyrosine and leucine, which were obtained in cryst. form, and qual. tests for proline. Basic cleavage products were not found in appreciable amt. The insol. residue from the hydrolysis was extd. with 2% NaOH, leaving a residue contg. 13.9% of the N of the original spores. A. W. DOX

Practical method for the determination of the chloride content of plant tissue fluids.

J. V. LAWRENCE AND J. A. HARRIS. *Ecology* 6, 391-6(1925).—A practical method for use in the field is given in detail.

The accumulation of dye in *Nitella*. M. IRWIN. *J. Gen. Physiol.* 8, 147-82 (1925).—When living cells of *Nitella* are placed in aq. solns. of cresyl blue of different concn. at p_H 6.9, the dye enters the cell sap. The greater the concn. of dye in the external soln., the greater is its speed of accumulation in the cell sap and the higher its concn. in the sap at equil. The process is a pseudounimol. reaction in which there is a chem. combination of the dye with a constituent of the cell. It is probably not an adsorption phenomenon because the temp. coeff. is high (about 4.9). Also when the log. of the dye concn. in the cell vacuole is plotted against that in the external soln. the slope of the straight line is 45° , which is not to be expected on the assumption that adsorption has taken place. The following explanations for the accumulation of dye in the cell sap are offered and discussed: (1) That it is a Donnan equil. phenomenon. (2) That the dye combines with cell protein. (3) That the undissociated dye hydroxide enters the cell whereas the dye salt and dye ions cannot enter. Further studies are in progress.

CHAS. H. RICHARDSON

Physiological and biochemical studies on cereals. IV. The presence of amino acids and polypeptides in the ungerminated rye kernel. S. L. JODIDI AND J. G. WANGLER. *J. Agr. Research* 30, 989-94(1925).—Polypeptides and amino acids occur in the ungerminated rye kernel as well as in the ungerminated kernel of wheat (*C. A.* 17, 3524), oats (*C. A.* 18, 2909) and maize (*C. A.* 19, 2361). The amino N in 3 varieties of ungerminated rye averaged 4.82% as calcd. on the basis of the total N, and 0.092% on the basis of the oven-dried kernel. The corresponding values for the peptide N in the same varieties were 6.40% and 0.129%, resp., and for the acid amide N, 4.27% and 0.084%.

W. H. ROSS

Some effects of seasonal conditions upon the chemical composition of American grape juices. J. S. CALDWELL. *J. Agr. Research* 30, 1133-76(1925).—Chem. analysis of the juices of a collection of 66 varieties of grapes grown together under control conditions at Vineland, N. J. were made annually from 1919 to 1923. The range of variation in compn. of the juice of any variety grown under const. conditions in one locality during a series of years is much narrower than the variation encountered on a large number of samples of a given variety grown over a wide area and under a variety of cultural conditions. Differences of soil and cultural conditions appear to affect varietal compn. more profoundly than do variations in environmental conditions encountered over a series of years in one location. There is a very definite and clearly marked effect of climatic conditions during the growing season upon the total sugar content, total astringency and titratable acidity of the fruit produced during that year. Under the environmental conditions in which this work was carried out the amount of sunshine received during the period of growth is subject to the greatest annual variation of the various climatic factors entering into the compn. of the seasonal conditions at Vineland and is the dominant factor in determining the chem. character of the fruit of a large number of grape varieties. Thus the year of max. sunshine for the period of March to Sept. was found to be the year of max. sugar content for a majority of the varieties and also the year of min. acid content and total astringency. Conditions which produce a max. accumulation of sugar in the fruit thus also favor a reduction of titratable acidity and astringent content to a low or min. value. A bibliography of 62 references is appended.

W. H. ROSS

Distribution of lignin in wood. GEO. J. RITTER. *Ind. Eng. Chem.* 17, 1194-7 (1925).—Microscopic and quant. studies of the changes taking place when wood is subjected to the standard procedures used in isolating cellulose and lignin indicate that about 75% of the total lignin is present in the middle lamella which apparently contains no pectins. Another type of lignin is found in the secondary layer of the wood ("cell-wall lignin"). "Middle lamella lignin" retains the general structure of the wood, may be mechanically sepd. from the other lignin, and has a MeO content of 10.8% (in western white pine) and 13.6% (in red alder). The amorphous lignin of the secondary layer contains 4.3-4.8% MeO. Excellent photomicrographs illustrate the article.

PHILIP B. HAWK

The development of antirachitic potency in phytosterol and cholesterol following irradiation. A. F. HESS, M. WEINSTOCK AND F. D. HELMAN. *Proc. Soc. Exptl. Biol.*

Med. 22, 227-8(1925).—Phytosterol, obtained from vegetable oils acquired antirachitic properties when irradiated with the Hg vapor quartz lamp. Cholesterol also became antirachitic and spectrograms showed the transmission of a greater intensity and wider range of the short ultra-violet radiations. C. V. B.

A diabetic diet; the line ration scheme. R. D. LAWRENCE. *Brit. Med. J.* 1925, I, 261-2.—Details of an elastic diet scheme for diabetics A. T. CAMERON

Irradiation of milk and the healing of rickets. S. J. COWELL. *Brit. Med. J.* 1925, I, 594-5.—Of 3 children with active rickets 2 received activated milk with marked benefit, the 3rd untreated milk, and remained in a stationary condition. A. T. C.

The causation and prevention of rickets. A WEBSTER AND L. HILL. *Brit. Med. J.* 1925, I, 956-60.—Further exptl work with rats indicating that certain rickets-producing foodstuffs can be made antirachitic by irradiation with ultra-violet light. Cholesterol and vegetable sterols are especially effective. A. T. CAMERON

The action of ultra-violet light upon the growth of rats. MISS M. E. HUME. *Brit. Med. J.* 1925, II, 341-2.—Light cannot be substituted for vitamin A indefinitely for the growth and well-being of the rat (which gradually under such substitution develops much increased tendency to respiratory disease) though it is not yet certain how far A is completely independent of light. Three rats kept in darkness on a diet deficient in fat-sol. vitamins for 4 months (and subsequently for 2 months on the same diet plus 0.4 g. spinach a day) grew slowly and were in fair condition. A. T. CAMERON

Foodstuffs irradiated with ultra-violet light; their effect on the bone lesions of rachitic children. HELEN M. M. MACKAY AND H. F. SHAW. *Brit. Med. J.* 1925, II, 344-5.—Rapid healing of bone lesions in children can be brought about by dried milk irradiated with ultra-violet light from the Hg arc. This antirachitic potency withstands 10 min. boiling. White flour similarly irradiated had little or no effect, and cottonseed oil probably slight effect. A. T. CAMERON

Vitamins. III. The water-soluble factor B. H. SIMONNET AND MISS L. RANDOIN. *Bull. soc. chim. biol.* 7, 678 749(1925)—A review. A. T. CAMERON

Discussion on non-specific disturbances of health due to vitamin deficiency. W. HUNTER, et al. *Proc. Roy. Soc. Med.* 18, 15-24(1925). A. T. CAMERON

Discussion: Is the modification of cow milk necessary in infant feeding? L. FINDLAY, E. PRITCHARD, H. THURSFIELD, R. C. JEWESBURY, H. C. CAMERON, B. MYERS, AND L. PARSONS. *Proc. Roy. Soc. Med.* 18, Sect. Dis. Children, 73-83(1925).—Arguments against and in favor are presented. A. T. CAMERON

The influence of *Ayuga chamaepitis* on the elimination of nitrogen in the normal individual. GIOVANNI MANGIANTE. *Arch. farm. sper.* 40, 58-70(1925).—Dietary expts., of which the author was the subject, showed that a daily addn. of 2.5-5.0 g of *Ayuga* to a fixed diet resulted in a marked retention of N, either by increasing the absorption of alimentary N or by retarding cellular metabolism. No impairment of health was observed during or after the expts. A. W. DOX

Growth factors. VI. HANS V. EULER AND SVEN STEFFENBURG. *Z. physiol. Chem.* 149, 195-202(1925).—The content of fat-sol. growth factor 1D and of antirachitic vitamin A1 in bone marrow and blood far exceeds that of most of the other organs and body fluids. It appears that the fat-sol. growth factor participates in blood formation and that the formed elements of the blood as well as the bone marrow are centers of activity of this factor. An expt. with parathyroid seems to indicate a high growth-promoting action and antirachitic action of constituents of this organ. The growth-promoting action of ultra-violet radiation shows an optimum after a certain period of irradiation or after the absorption of a certain amt. of energy. When this is exceeded an inhibition from unexplained causes is observed which finally exceeds the activation A. W. DOX

Hyperglucemia produced by glycerol. CARL VOEGTLIN, J. W. THOMPSON AND EDITH R. DUNN. *J. Biol. Chem.* 64, 639-42(1925).—"Glycerol given to fasting rabbits produces a hyperglucemia of considerable extent and duration, indicating a conversion of glycerol into glucose." I GREENWALD

Animal calorimetry. XXIX. Fat production in a young hog. M. WIERZUCHOWSKI AND S. M. LANG. *J. Biol. Chem.* 64, 697-707(1925)—"The basal metabolism of a growing hog from the 70th to the 117th day of its life, during which time it increased in wt from 8.5 to 18.1 kg., averaged 1085 cal. per day per sq. m. of body surface, within a \pm variation of 3%. The hog showed a continued capacity for retaining the N of milk protein in large amts. when milk and starch formed the basis of the diet. When starch and glucose were given together on the morning of a day following a large ingestion of starch, the metabolism rose 100% above the basal and the production of fat from carbohydrate amounted to a storage of energy in the form of fat equal to 260% of the basal

metabolism. Estd. on a 24-hr. basis, the hog has a capacity of using ingested carbohydrate so that more than 0.5 of the material is employed for fat construction. After giving starch to a hog the respiratory quotients were maintained at about 1.40 during at least 20 hrs. The highest quotient obtained was 1.58. During 12 hourly periods, the heat calcd. by the indirect method was 417.6 cal., and the "heat eliminated" by the hog (body temp. changes disregarded) was 426.8 cal. . . . Though the production of fat from carbohydrate did not exceed 2 mg. per second, yet in 24 hrs. the rate of production reached at times 125 g. per day or 0.9% of the hog's wt." I. G.

The relation of thyroid secretion to specific dynamic action. L. J. BAUMANN AND LOUISE HUNT. *J. Biol. Chem.* 64, 709-26(1925).—"Complete thyroidectomy (in rabbits) caused a gradual decrease and final disappearance of specific dynamic action after about 65 days. Restoration of specific dynamic action. . . was accomplished by feeding thyroid gland. Incomplete thyroidectomy caused a decrease of specific dynamic action, which would be increased again by feeding thyroid and in some cases by feeding a small amount of KI." I. GREENWALD

Quantitative aspects of the function of vitamin B in several species. G. R. COWGILL, A. H. SMITH AND H. H. BEARD. *Proc. Am. Soc. Biol. Chem., J. Biol. Chem.* 63, xxiii-xxiv(1925).—Data obtained from 3 widely different species of animals (mouse, rat and dog) indicate that the vitamin B requirement is closely related to metabolism. In the adult animal the vitamin B requirement is very closely proportional to the product of: (1) the two-thirds power of the wt., which may indicate surface or "active protoplasmic mass" or whatever the metabolism depends on, (2) the quantity of energy handled as indicated by the total calories utilized from the food, and (3) the body wt. The following formula embracing these factors has been constructed. By it a number called provisionally the "vitamin B constant" may be calcd.

$$\frac{\text{Vitamin B per day}}{\text{Weight}^{2/3}} = K_{\text{vitamin}} \times \text{calories per day} \times \text{weight}, \quad (a)$$

whence

$$K_{\text{vitamin}} = \frac{\text{vitamin per day}}{\text{calories per day} \cdot \text{weight}^{2/3} \cdot \text{weight}} \quad (b)$$

$$K_{\text{vitamin}} = \frac{\text{vitamin}}{\text{calories} \cdot \text{weight}^{4/3}} \quad (c)$$

This formula gives good agreement with exptl. data for adult rats, dogs and mice. During growth some other factor, as yet undefined, appears to affect the vitamin requirement, K_{vitamin} during this period, having a higher value. I. G.

Carbohydrate-phosphate metabolism. J. ABELIN. *Klin. Wochschr.* 4, 1732 (1925).—The respiratory quotient is raised when carbohydrate (glucose, maltose, sucrose or starch) is fed. The respiratory quotient is scarcely elevated and the CO_2 production is increased very little when phosphate is fed with the carbohydrate. From this one would conclude that the carbohydrate is not burned; hence it might be stored as glycogen. Expt. has shown that it is not stored as glycogen. A satisfactory explanation is not given. MILTON HANKE

The influence of hunger, and of diets rich or deficient in sodium chloride, on the gastric secretion. CHRISTINE JAKLE. *Klin. Wochschr.* 4, 2059-61(1925).—The salt content of the diet has no influence upon the acid content of the gastric juice collected either shortly after awakening or after partaking of a test meal. The acidity of the gastric juice is increased by starvation. MILTON HANKE

An improved technique for use with synthetic diets. G. A. HARTWELL. *Biochem. J.* 19, 729-32(1925).—To improve synthetic diets, so that the compn. and texture approximate more closely to those of ordinary foods, mix 22 g. of a sythetic mixt. consisting of 20 g. caseinogen, 64 g. starch, 4 g. salt mixt.) to a smooth paste with warm distd. water at 40°, add 10 cc. of marmite soln. and 3 g. butter (melted) and mix the whole well. Place mixt. in the inner saucepan of a double boiler, the outer pan of which contains boiling water, and stir rapidly until it thickens. BENJAMIN HARROW

Note on the effect of high temperatures on the accessory food factor content of cod-liver oil. H. W. SOUTHGATE. *Biochem. J.* 19, 733-6(1925).—Even when oxygen is excluded, heating cod-liver oil to 300° destroys the antirachitic and growth-promoting factors. BENJAMIN HARROW

Effect of alcohol, under varying conditions of diet, on man and animals, with some observations of the fate of alcohol in the body. H. W. SOUTHGATE. *Biochem. J.* 19, 437-45(1925).—Once the max. concn. of alcohol in the blood has been reached, provided

the subject be at rest, the subsequent rate of disappearance of alc. from the blood is independent of concn. The effect of a previous meal of a foodstuff such as bread and milk in depressing the concn. curve is demonstrated. This is shown to be due not to delayed absorption, but to the fact that a considerable fraction of the alcohol ingested is never manifested in the blood stream. The concn. of alc. in the urine exceeds that of the blood over a period of 1-6 hrs. after ingestion by about 40-50%; the passage of alc. through the kidney into the urine cannot, therefore, be merely a diffusion process.

BENJAMIN HARROW

Biochemical study of by-product yeast. J. S. HEPBURN. *J. Franklin Inst.* 200, 767-70(1925).—Dried by-product yeast was used as the sole source of water-sol. B vitamin in the otherwise complete ration of albino rats for a period of 400 days. Yeast from an industrial alc. plant was given for 11 days, beer yeast for 89 days, alc yeast for 300 days. The rats grew, remained healthy, and reproduced to the third generation. The com. utilization of this trade waste as a source of vitamin B is suggested.

JOSEPH S. HEPBURN

The elaboration of antirachitic vitamin D in germinating seeds. WILHELM STEPP. *Z. Biol.* 83, 99-101(1925).—Vitamin D is not elaborated during generation. F. K.

The action of the parenteral supply of vitamin A and vitamin D in experimental avitaminosis. WILHELM STEPP. *Z. Biol.* 83, 102-6(1925).—Parenteral administration of vitamin A relieves entirely the eye affection caused by the lack of it. Intraperitoneal injection of 2 cc. cod-liver oil every 3 or 4 days showed distinct improvement in rachitic animals.

FRANCES KRASNOW

Vitamin B in the excreta of rats on a diet low in this factor. W. D. SALMON. *J. Biol. Chem.* 65, 457-62(1925).—The consumption of feces by rats on diets low in vitamin B may result in significant error. Addn. of 20% of extd. velvet beans caused resumption of growth in rats when they had access to their excreta although the beans contained no demonstrable amt. of vitamin B. This result may have been due to increased undigested food residues in the intestinal tract which made conditions more favorable for bacterial activity. Rats given 10% of dried feces from this diet grew at a rate comparable with that of Steenbock's rats that received 40% of corn or oats as the source of vitamin B. Efforts should be made, therefore, to reduce fecal consumption to a min in vitamin B diets. Cf. McCollum, *et al.*, *C. A.* 19, 2066.

A. P. LOTHROP

The concentration of vitamin B. II. P. A. LEVENE AND B. J. C. VAN DER HOEVEN. *J. Biol. Chem.* 65, 483-9(1925); cf. *C. A.* 18, 1851, 3638.—The Osborne and Wakeman concentrate of yeast may be further concd. by successive pptn., first by basic Pb acetate and second by Ba(OH)₂. The product obtained contained 5.2% N (calcd. on the ash-free basis) and was potent in daily doses of from 2.0 to 4.0 mg. The mineral impurities can be removed by dissolving in the min. amt. of HCl of 1.19 sp. gr. and adding enough 98% alc. to make the alc. concn. 70%; this product has an elementary compn. approaching carbohydrates, yields reducing sugars on hydrolysis, contains about 4% of N and is potent in daily doses of 1.25 mg.; from it can be obtained by treatment with SiO₂ gel and extrn. at *p*_H 9 a product potent in doses of 0.6 mg. per day contg. 4% of N. The original Pb-Ba ppt. has a P-contg. impurity which is apparently essential for good selective adsorption by SiO₂ gel, for from it the most active material was obtained; it was potent in daily doses of 0.1 mg. contg. 0.015 mg. of N.

A. P. LOTHROP

Is the antirachitic factor of cod-liver oil, when mixed with ground grains, destroyed through storage? E. B. HART, H. STEENBOCK AND S. LEFKOVSKY. *J. Biol. Chem.* 65, 571-8(1925).—"Appreciation of the fact that cod-liver oil has potent antirachitic properties has led to its direct mixing with foods designed for human consumption, particularly infant foods, and also with feeds intended for animal nutrition, especially poultry feeds. Such practice has raised the question of the permanency of the antirachitic properties of this mixt. after several months of storage." Expts. conducted with baby chicks indicate that cod-liver oil mixed with ground grains and stored in covered galvanized iron cans at room temp. retains its calcifying power for at least 6 months.

A. P. LOTHROP

The nutritional requirement of the chicken. V. The influence of ultra-violet light on the production, hatchability and fertility of the egg. E. B. HART, H. STEENBOCK, S. LEFKOVSKY, S. W. F. KLETZIEN, J. G. HALPIN AND O. N. JOHNSON. *J. Biol. Chem.* 65, 579-95(1925).—"The egg production of hens is greatly influenced by the supply in the diet or environment of the antirachitic factor, even when there is plenty of lime in the ration. Groups of hens continued to lay abundantly when given in addition to their ration an exposure to ultra-violet light of 10 min. daily; those not receiving the ultra-violet light decreased their egg production practically to the zero point. Feeding cod-liver oil or irradiating hens after a long confinement to a rachitic ration with

resultant decrease in egg production again stimulates and increases egg production. Irradiation of hens greatly improves the hatchability of the eggs. Under the influence of ultra-violet light hatchability was sustained at 60–70% while in its absence the hatchability receded to zero. Irradiation increased markedly the amt. of lime in the shell as compared with eggs from non-irradiated hens. This fact is of significance in the marketability of the egg. The Ca and P content of the whites and yolks of the two groups was not distinctly different. The developing embryo from the eggs of irradiated hens contained, after 21 days of incubation, nearly twice as much lime as the embryo from non-irradiated hens' eggs. The low hatchability on the rachitic ration is probably related to the low power of the developing embryo to transfer lime from the shell. The antirachitic potency of egg yolks from irradiated hens was approx. about 10 times that of the egg yolks from non-irradiated hens. Fertility of the eggs was not consistently influenced by a paucity or abundance of the antirachitic factor." A. P. LOTHROP

The influence of sunlight on bone development in swine. L. A. MAYNARD, S. A. GOLDBERG AND R. C. MILLER. *J. Biol. Chem.* 65, 643–55 (1925).—Sunlight has a markedly favorable influence on the mineral nutrition of growing pigs fed a ration low in Ca and in the factor aiding Ca assimilation. All the pigs fed on the ration without access to direct sunlight developed characteristic stiffness within 4 months. Sunlight in general also caused an increase in the ash content of the bones and histological studies showed the production of more nearly normal bone. Normal bone is produced only when the diet contains sufficient amts. of Ca. "From a practical standpoint the results indicate that the common observation, that both growing pigs and brood sows keep in better condition and are less likely to develop stiffness on pasture than when they are housed inside, may be explained on the basis of sunlight as well as of feed. It is also indicated that it is good practice to let the pigs spend a part of each day outdoors, in winter as well as summer, whenever the weather is not too severe, and that healthier and better nourished animals may result therefrom." A. P. LOTHROP

Fat-soluble vitamins. XXV. The antirachitic action of irradiated animals on the non-irradiated when placed in the same cage. E. M. NELSON AND H. STEENBOCK. *Am. J. Physiol.* 73, 341–5 (1925); cf. *C. A.* 19, 2691.—The protection from rickets of white rats fed rickets-producing diets by the presence of other rats similarly fed but radiated with ultra-violet light is not due to radiations given off by the treated animals but rather to the presence of antirachitic substances in the excreta. Minute amts. of the excreta from radiated animals seem to protect the non-radiated rats. J. F. L.

The utilization of minerals by ewes during the period of gestation. A. R. WINTER. *Am. J. Physiol.* 73, 379–86 (1925).—Five ewes in the early period of pregnancy showed positive balances for N, S, Mg, P, Na and K in all cases on rations contg. timothy hay or alfalfa as roughage supplemented or not by bone meal. The Cl balances were variable. Of 22 Ca balances, covering nearly all stages of the gestation period, 15 were negative, indicating a poor assimilation of the Ca of timothy and alfalfa hay. J. F. L.

The basal metabolism of some orientals. GRACE MACLEOD, ELIZABETH E. CROFTS AND F. G. BENEDICT. *Am. J. Physiol.* 73, 449–62 (1925).—The basal metabolism of oriental women (7 Chinese and 2 Japanese, college students, living under American conditions) was strikingly low, 10.4% below the Harris and Benedict prediction standard. This is thought to be due to the sp. low cell metabolism characteristic of Orientals and that American and English physiol. standards cannot be applied to Orientals.

J. F. LYMAN

The apparent digestibility of low protein rations by dairy cows. A. E. PERKINS AND C. P. MONROE. *J. Dairy Sci.* 8, 405–14 (1925); cf. *C. A.* 19, 2365, 2971.—All cows were on a ration with a nutritive ratio 1:11, receiving 70% as much protein and 158% as much net energy as called for by the Armsby standard. The observed digestibility of each nutrient in the ration was less than the commonly accepted average digestibility. Et₂O ext. was less than half. Changing cows from distd. to tap H₂O did not affect the results. Cows which had been on a low protein ration previous to the expt. gave results similar to those previously on a liberal ration. There was some indication that molasses in the ration was one factor causing lowered digestibility. FRANK E. RICE

The influence of diet upon the production of mouse carcinoma. W. EBER, FR. KLINGE AND L. WACKER. *Z. Krebsforschung* 22, 359–64 (1925).—Diets rich in cholesterol and scarlet red hasten the formation and metastasizing of exptl. mouse carcinoma. The growth-exciting activity is attributed to the cholesterol, because very often in rabbits fed on a similar cholesterol-rich diet there appears on the bottom of a cirrhosis-like liver injury, a proliferation of the liver sinus walls resembling bile ducts. F. B. S.

The vitamin content of cortex limonis, Brit. Pharm.; preliminary note. S. G. WILLIMOTT AND F. WOKES. *Pharm. J.* 115, 164–8; *Chemist & Druggist* 103, 187–8

(1925).—Feeding expts. on rats showed that lemon peel contains considerable quantities of vitamin, although not sufficient to insure growth at the max. rate. Expts. are under way to clear up the wide divergence in growth and well-being between the male and the female rats receiving lemon peel, as the latter failed to respond to a subsequent doubling of the supply of lemon peel, or to adding the known fat-sol. A requirement for the rat. The vitamins A, B and C are all readily sol. in alc. of 75–90%. Fat-sol. A becomes less sol. as the alc. strength decreases. Vitamin C is the most easily affected by heat in even weak alk. soln. (C. A. 14, 192); the presence of the org. acid is a protective in heating (C. A. 14, 2016) and in drying (C. A. 12, 2612). A bibliography of 22 references* is given.

S. WALDBOTT

Tissue changes following deprivation of fat-soluble A vitamin. S. B. WOLBACH AND P. R. HOWE. *J. Exptl. Med.* 42, 753–77(1925).—The sp. tissue changes which follow the deprivation of fat-sol. vitamin A in albino white rats and in the human concerns epithelial tissues. These pathol. changes are described in detail. C. J. W.

Influence of high-protein diet on the kidneys. A. J. MILLER. *J. Exptl. Med.* 42, 897–904(1925).—No evidence of kidney damage (blood uric acid and urea detns. and microscopic examns. of the tissues) was found in rats fed on diets contg. protein varying in amt. from 1.36 to 40.13% (derived mainly from grain, casein, meat and milk with carbohydrate, fat and vitamins). There was evidence of kidney hypertrophy consisting of increased wt. of the kidney, large diams. of the capillary tufts, convoluted tubules and kidneys in the animals receiving high-protein diet. C. J. WEST

ANDREW HUNTER

A study of the occurrence of peptide nitrogen in the blood. W. W. SWANSON. *Proc. Soc. Exptl. Biol. Med.* 22, 193–4(1924).—Tungstic acid blood filtrate was boiled with satd. Ba(OH)₂ soln. for 20–24 hrs. The Ba was pptd. with H₂SO₄ and the Folin method was used to det. free and hydrolyzed amino acids. The difference between free and total amino acid N was considered as peptide N and this constituted 72–93% of the undetd. N of human blood. C. V. B.

Blood calcium in relation to sex in pigeons. O. RIDDLE AND H. E. HONEYWELL. *Proc. Soc. Exptl. Biol. Med.* 22, 222–5(1925).—The detns. were made by the method of Kramer and Tisdall and include appreciable but unknown amts. of Mg. The results fall into sex groups; the females had notably higher amts. of Ca in the blood. No classification could be made on the basis of health, age or body wt. The females included those actively producing eggs. C. V. B.

Intermediary carbohydrate changes in the muscles under identical conditions of gas metabolism (normal, starvation, insulin action). IX. T. BRUGSCH, H. HORSTERS AND J. VORSCHÜTZ. *Biochem. Z.* 158, 144–66(1925).—CO₂ production, O₂ utilization and changes in sugar, lactic acid, H₃PO₄ concn. of muscle tissue suspended in Ringer soln. in closed flasks was followed under various conditions, and indicated the importance of δ -fructosediphosphoric acid as a factor in intermediary carbohydrate metabolism in muscles. Cf. C. A. 19, 3302.

F. A. CAJORI

A red pigment prepared in a pure condition from human urine by treatment with *p*-dimethylaminobenzaldehyde. G. SCHEFF. *Biochem. Z.* 158, 167–9(1925).—Crystals of a red pigment, similar to those described by Hari (C. A. 15, 2446), were obtained by boiling normal urine with animal charcoal, extg. the charcoal with EtOH and treating with the aldehyde reagent. **Determination of a red pigment produced from human urine by treatment with *p*-dimethylaminobenzaldehyde.** *Ibid.* 170–5.—Measurements in the spectrophotometer of the extinction coeff. of alk. solns. of the red pigment prepd. from urine permits detn. of the concn. of this pigment in urine samples. It was found that on meat diets the pigment was excreted in greater amts. and its origin is probably in the food proteins.

F. A. CAJORI

The chlorination of fluids in its relation with the velocity of mineral exchanges and the selective character of cellular permeability. W. MESTREZAT AND MISS Y. GARREAU. *Bull. soc. chim. biol.* 7, 860–7(1925); cf. C. A. 19, 1807, 2292, 2346.—The presence of NaCl in fluids allows exchanges (anions of waste products or for anabolism) with the tissues to be effected with the rapidity necessary for life. Cations are generally integral parts of the tissues. While other factors (variable polarization, solubility in membranes, etc.) may play a part, the presence of NaCl in tissue fluids seems to be the primordial cause of the phenomena of selectivity. The approx. 0.1 N concn. of NaCl in the blood is that which is found experimentally to be most efficacious in augmenting

the velocity of diffusion of univalent and divalent ions, those most abundant in the organism.

Basal metabolic determinations in 250 Winnipeg school children. A. T. CAMERON. *Can. Med. Assoc. J.* 15, 1022-5(1925).—As detd. with clinical app., distinctly higher values have been found for normal children than Benedict's and Talbot's predicted figures. The differences are attributed chiefly to climatic effects. Of 163 goitrous children examd. probably not more than 2.5% were definitely above max. normal limits, and none was definitely below.

Action of carbon dioxide on organic oxidations. A. OZORIO DE ALMEIDA. *J. physiol. path. gén.* 23, 525-31(1925).—In frogs intact or with the cord sectioned increase of CO_2 tension produces an exaggeration of the respiratory exchanges, while in frogs with the nervous system destroyed it produces a marked reduction. CO_2 has therefore an inhibiting action on tissues, which is masked in the normal animal.

The humoral transmission of the excitation of cardiac nerves. M. POPPER AND G. RUSSO. *J. physiol. path. gén.* 23, 562-71(1925).—Stimulation of the autonomic nerves of the frog heart produces sp. substances whose action seems to be similar to that of the nerves themselves. Their nature is not known, but they do not appear to be sp. to species, since, obtained through stimulation of the vagus nerve of the rabbit, they are active to the frog heart.

Renal perfusion. P. CARNOT AND P. RATHERY. *J. physiol. path. gén.* 23, 625-37(1925).—Dogs in a condition approaching anesthesia caused by removal of half their blood had their kidneys perfused *in situ* with 0.4% citrated blood from other dogs, the kidneys functioning normally during the expt. and the urine being free from blood and albumin. The blood used for perfusion was modified as desired. Urea is always coned. in kidney secretion, but NaCl may show increased or decreased concn. The concn. of urine glucose is always less than that of blood for normal blood, but concn. appears to take place when there is considerable hyperglucemia.

The regeneration of carbohydrate in the muscle of warm-blooded animals. S. JANSSEN AND H. JOST. *Z. physiol. Chem.* 148, 41-61(1925).—During rest the blood-perfused muscle of warm-blooded animals takes up small amts. of glucose and returns similar amts. of lactic acid to the circulation. After raising the lactic acid picture by infusion, the resting muscle takes up large quantities of this substance from the blood. Directly after discontinuance of the infusion the extn. of lactic acid ceases and the lactic acid is then gradually given back. In this period of liberation the arterial picture drops very rapidly to nearly normal. Hence it is not the musculature, for which no definite basis for an oxidative carbohydrate synthesis can be recognized, but other organs which remove the greater part of the lactic acid from the body. Since only an insignificant portion of the infused lactic acid is excreted by the kidneys, the inference is that the liver takes up the lactic acid and utilizes it for carbohydrate synthesis. The disintegration of carbohydrate whereby energy is supplied occurs in the muscle, while the regeneration of the source of energy takes place in the liver at the expense of all nutrients.

The chemism of rigor mortis. HANS-JOACHIM DEUTICKE. *Z. physiol. Chem.* 149, 259-97(1925).—In rigor mortis a considerable increase in lactic acid and H_3PO_4 occurs. This acid formation is not the direct cause of rigor, since a reduction in amt. of acid by treatment of the stimulated muscle with O does not prevent the onset of rigor. Other factors are of greater importance, such as alterations in the muscle colloids which bring about a loss of ability to esterify H_3PO_4 with carbohydrate under the favorable influence of F ions. These colloid changes are probably a sequence of the acid formation during previous stimulation, along with other deleterious influences, in such manner that the acid shocks of stimulation result in an irreversible change in the colloids which continues after the acid action has ceased. In advanced rigor the muscle loses its ability to esterify H_3PO_4 but still retains the power of splitting added hexosediphosphoric acid into lactic acid and H_3PO_4 . Hexosediphosphoric acid was the only substance the addn. of which resulted in lactic acid formation. Addn. of glycogen had no effect. This behavior corresponds to earlier observations on press juice and supports the view that the intramuscular degradation of carbohydrate to lactic acid requires an intermediary synthesis with phosphate, especially since the capacity of the musculature to synthesize hexosediphosphoric acid under the strongly favoring influence of F ions is completely lost in rigor mortis.

The normal bilirubin content of blood. GYULA FÖRSTER. *Klin. Wochschr.* 4, 1689-90(1925).—Treat 2 cc. of serum with 3-4 cc. of colorless acetone, filter and exam. the clear filtrate colorimetrically, for bilirubin. The color is entirely due to bilirubin because lipochromes are not present in normal serum. A 1:6000 soln. of $\text{K}_2\text{Cr}_2\text{O}_7$

is used for comparison. The minimum amt. determinable is 0.2 mg. %. The normal bilirubin value may vary from 0.2 to 1.0 mg. %; hence a value in excess of 0.5 mg. %, the former upper limit of normality, does not necessarily indicate disease. M. H.

The specific dynamic action of protein in children before and during the period of puberty. OSKAR GÖTTCHÉ. *Klin. Wochschr.* 4, 2062-4(1925).—The sexual hormone and the thyroid hormone increase the basal metabolic rate and decrease the specific dynamic action of protein. The action of the hypophyseal hormone is the reverse of the above. In short, the hypophysis is antagonistic to the thyroid and to the sex glands. Ingestion of protein by adults increases the oxidation process by 30%. In young children (pre-puberty period) protein calls forth only a 20% increase in the oxidation rate. In such children the hypophysis and thyroid are active; but the sexual hormone is absent. The action of the hypophysis is predominant. The early stages of puberty are characterized by a 10-35% increase in the basal metabolic rate and a marked decrease in the specific dynamic action of protein, the mean value being about 5% as compared to 30% in adults. The influx of the new hormone has destroyed the previously existing balance between hypophysis and thyroid with a temporary suppression of the hypophyseal activity. The period of puberty is associated with a tendency to establish a new balance between the endocrine organs so that the basal metabolic rate steadily decreases to normal and the specific dynamic action of protein steadily rises to the adult value of 30%. MILTON HANKE

Distribution of phosphorus compounds in the blood. R. V. STANFORD AND A. H. M. WHEATLEY. *Biochem. J.* 19, 706-9(1925).—The av. figures are (representing per cent of total P): in plasma, inorg. 5, lipin 10, "unknown" 0; in corpuscles, inorg. 3, lipin 17, "unknown" 65. BENJAMIN HARROW

Excretion of purine derivatives. FINAR LANGFELDT AND JÖRGEN HOLMSEN. *Biochem. J.* 19, 717-23(1925).—In dogs on a meat diet purine derivs. are excreted in amts. which largely exceed the purine content of the meat; also, dogs on a purine-free diet excrete such large amts. of purine derivs., that a synthesis is most plausible. The expts do not permit conclusions as to which amino acids may be the raw materials for the synthesis of purines. The amt. of the synthesized allantoin and uric acid varies in the different dogs on the same diet. BENJAMIN HARROW

The presence of glutathione in the corpuscles of mammalian blood. H. F. HOLDEN. *Biochem. J.* 19, 727-8(1925).—Four liters of sheep blood was freed from protein with tungstic acid (see C. A. 13, 2541) and the ppt. was well washed with cold water. To the united filtrate and washings was added 35 cc. of 10% HgSO_4 in 5% H_2SO_4 for each liter of fluid. The ppt. was filtered off, washed with cold water, decomposed with H_2S , and the H_2SO_4 exactly removed with baryta. The filtrate was concd. under diminished pressure to 50 cc and enough H_2SO_4 added to make the soln. semi-normal. Phosphotungstic acid dissolved in 0.5N H_2SO_4 was added till the max. ppt. was obtained. The ppt. was filtered off, washed, decomposed with baryta, the Ba tungstate removed by filtration and the excess baryta removed with H_2SO_4 . The soln. was concd. to a sirup and on the addition of alc. a white powder was pptd. The product proved to contain "neutral" S and amino N. After reduction it yielded the nitroprusside reaction. It had the same m. p. as glutathione from other sources, and when mixed with a specimen of pure glutathione from yeast the m. p. was unchanged. After acid hydrolysis characteristic crystals of glutamic acid hydrochloride were obtained. No trace of the glutathione could be found in sheep plasma, but it is present in the corpuscles of sheep, goats, rabbits and rats in the reduced form. The glutathione is apparently the chief optically active constituent of deproteinized blood other than glucose; and as such is responsible for the effects recorded by Wintgr and Smith (C. A. 17, 2736) and others, and quoted as evidence in favor of the presence of an unstable modification of glucose. The glutathione probably accounts for the "neutral" S in blood. B. H.

Relation between the pancreas and the carbohydrate metabolism of muscle. II. Antiglyoxalase and glyoxalase. D. L. FOSTER. *Biochem. J.* 19, 757-67(1925); cf. C. A. 18, 3210.—The factor in the pancreas able to inhibit the production of lactic acid by chopped muscle *in vitro* is not antiglyoxalase. The "antiglyoxalase" is probably due to the action of some factor in the pancreas on phenyl-glyoxal rather than on glyoxalase. Rabbit muscle does not contain glyoxalase and here lactic acid is produced without the action of glyoxalase; presumably, therefore, the lactic acid does not arise from methylglyoxal. The glyoxalase used in these expts. was obtained from minced chicken muscle. BENJAMIN HARROW

Some observations on the normal sugar content of blood and the sugar tolerance test. S. L. BHATIA AND G. CORLHO. *Indian J. Med. Research* 13, 41-51(1925).—In

non-vegetarians the av. blood sugar was lower, tolerance for carbohydrates greater and glycosuria less common than in vegetarians. The significance is discussed. F. K.

The transition of plasmalogens into plasmal with special reference to gastric conditions during digestion. K. VOIT. *Z. Biol.* 83, 223-30(1925).—The action of acids in changing plasmalogen into plasmal (*i. e.*, to make manifest the aldehyde groups) is a function of the H ion, time and temp. When gastric acidity is sufficient for peptic digestion, the greater portion of plasmalogen is changed to plasmal. F. K.

The isoelectric point of muscle proteins. EDGAR WÖHLISCH AND HANS SCHRIEVER. *Z. Biol.* 83, 265-82(1925).—The isoelec. point values for the various substances studied are: "ammonium sulfate myosin" $p_H = 5.4$; "dialysis myosin" $p_H = 4.8$; myogen $p_H = 4.4 \pm 0.2$; myoprotein $p_H = 3.3$. The hypothesis of Hill and Meyerhof, that the contraction of muscle is dependent on protein ionization, may be applied. Myosin may act as the contraction protein while myogen may play the role in buffering the acid formed.

FRANCES KRASNOW

The reciprocal transformation of creatine and creatinine. AMANDUS HAHN AND HUGO FASOLD. *Z. Biol.* 83, 283-8(1925).—After many subcutaneous injections of creatine, creatinine excretion did not increase. Moreover, the injected creatine was not recovered. In being utilized by the body, it is transformed into a substance yet unknown.

FRANCES KRASNOW

Elimination of carbon monoxide from the blood. A theoretical and experimental study. W. C. STADIE AND K. A. MARTIN. *J. Clin. Invest.* 2, 77-91(1925).—An equation is derived for the relation between hemoglobin, O_2 , CO and p_H at equil. Expts. *in vitro* substantiate it. Increased H-ion concn. hastens the elimination of CO in dogs regardless of the rate of ventilation, thus explaining the chief beneficial effect of CO_2 inhalation. Hyperventilation with air has little effect upon CO elimination. CO alters the O_2 dissociation curve, which results in marked lowering of partial pressure of O_2 in the capillaries, giving the basis for anoxemia.

LOUIS LEITER

The isolation from blood of a hitherto unknown substance, and its bearing on present methods for the estimation of uric acid. GEORGE HUNTER AND BLYTHE A. EAGLES. *J. Biol. Chem.* 65, 623-41(1925).—A new substance, believed to be a simple pyrimidine nucleoside and having the empirical formula $C_6H_{11}N_2O_3$, has been isolated from pig blood. It is also present in human whole blood to the extent of 10 to 12 mg. per 100 cc. and is confined entirely to the corpuscles. The amt. varies over a wide range even in the same individual. The substance gives a blue color with phosphotungstic and arsenophosphotungstic acid uric acid reagents in the presence of either Na_2CO_3 or NaCN. Its presence in human blood is made more conspicuous by using Na_2CO_3 , as with this alkali the reagent is less sensitive towards uric acid. "The behavior of the new substance has been quant. studied with the old and new uric acid reagents and the conclusion has been reached that the discrepancies between the direct method of Benedict and the pptn. method of Folin and Wu for the estn. of uric acid in human blood are due to the fact that this new substance adds to the values obtained for uric acid by the direct method. The substance which has now been isolated is that mainly responsible for the direct 'uric acid' values recently obtained in animal bloods by Bulmer, Eagles and Hunter (*C. A.* 19, 1437), and is separable from uric acid in blood filtrates by the pptn. method of Folin and Wu." The substance is also present in dog, rabbit and other animal bloods.

A. P. LOTHROP

Energy expenditure of women during horizontal walking at different speeds. H. M. SMITH AND DOROTHY B. DOOLITTLE. *J. Biol. Chem.* 65, 665-76(1925).—"The energy expenditure of women during horizontal walking is of the same degree as that of men when walking at moderate speeds, (60 and 90 m. per min.); this value is from 0.45 to 0.55 g. cal. per horizontal kilogrammeter. The energy expenditure is greater at an abnormally slow speed (30 m. per min.) than at moderate speeds. The menstrual period appears to be without definite influence on the standing metabolism." A. P. L.

Studies of gas and electrolyte equilibria in blood. VIII. The distribution of hydrogen, chloride and bicarbonate ions in oxygenated and reduced blood. D. D. VAN SLYKE, A. BAIRD HASTINGS, C. D. MURRAY AND JULIUS SENDROY, JR. *J. Biol. Chem.* 65, 701-28(1925).—"The distribution of the diffusible ions, H^+ , Cl^- , and HCO_3^- , between serum and cells of horse blood has been studied over the p_H range 7.0 to 7.6, and in oxygenated and reduced blood. The exptly. detd. distribution ratios are related as follows: $[\alpha_{H^+}]_s/[\alpha_{H^+}]_c = 0.77$ $[Cl]_s/[Cl]_c = 0.62$ $[HCO_3]_s/[HCO_3]_c$; α_{H^+} represents hydron activity electrometrically detd. and $[Cl]$ and $[HCO_3]$ represent molalities, in terms of moles of chloride and bicarbonate per kg. of H_2O . The activity coeff. of HCO_3 in serum estd. from detd. $[H_2CO_3]$, $[BHCO_3]$, and p_H values was found to be related to the ionic strength in the manner predicted for salt solns. by the theory of Debye and

Hückel. For cells, however, the ionic strength as calcd. by us indicated a much greater activity coeff. than that found. It appears that in cells unknown factors influence either the activity coeffs. or the potential readings obtained with the H electrode. The changes in the distribution of α_{H}^+ , Cl, and HCO_3 between serum and cells with change in serum p_{H} and in degree of oxygenation of the hemoglobin approximate those predicted by Van Slyke, Wu, and McLean (*C. A.* 17, 3046), from changes in base-binding power of the cells and serum proteins caused by varying p_{H} and oxygenation." A. P. L.

The influence of protein concentration on the conductivity of human serum. D. W. ATCHLEY AND EMILY G. NICHOLS. *J. Biol. Chem.* 65, 729-34 (1925).—When human serum proteins which have been prepd. so they suffer few, if any, phys. changes during their prepn. are added at p_{H} 7.4 to a pure salt soln. of sp. cond., about 136×10^{-4} at 25°, each additional g. of protein per 100 cc. was found to decrease the cond. of the salt soln. 1.58%. This produces a cond. of about 120×10^{-4} for 7.5% protein. A. P. L.

Changes in the composition of the urine after muscular exercise. D. W. WILSON, W. L. LONG, H. C. THOMPSON AND SYLVIA THURLOW. *J. Biol. Chem.* 65, 755-71 (1925); cf. *C. A.* 19, 1730.—The strenuous exercise consisted of running up and down a flight of stairs as rapidly as possible while swinging the arms vigorously during short periods of from 1 to 3 min. The urine was collected in 10-min. periods. There was a diminution in the urine vol. which could not be overcome by drinking even large amts. of H_2O but there was no evidence of perspiration so that there was no excessive losses by way of the skin and lungs. The urinary acidity increased to p_{H} 5.5 to 5.0 irrespective of the reaction during the fore period. The titratable acidity was nearly doubled and the NH_3 increased 2-5 times. The excretion of inorg. phosphates increased and that of chlorides decreased. There was no significant change in creatinine. These changes reached a max. within 20 to 30 min. and normal values were again found within 40 to 90 min. after 1 to 2 min. of exercise. **The excretion of lactic acid in the urine after muscular exercise.** S. H. LILJESTRAND AND D. W. WILSON. *Ibid.* 773-82; cf. *C. A.* 19, 1730.—The excretion of lactic acid in the urine after 2-3 min. of strenuous exercise (stair running) was studied in 10 and 15 min. periods. The excretion reached max. values varying from 86 to 630 mg. during the 2nd 10 min. period and the elimination thereafter diminished and reached normal values in 30-50 min. The total amt. excreted after one period of exercise varied from 140 to 1370 mg. and similar amts. were excreted after a 2nd period of exercise following shortly after the 1st. The acid excreted was *d*-lactic acid; Zn sarcosylate was isolated. A. P. LOTHROP

The influence of orally administered calcium salts on the serum calcium of normal and thyreoparathyroid dogs. A. M. HJORT. *J. Biol. Chem.* 65, 783-95 (1925).—The absorption of Ca salts such as the lactate, chloride, and glycerophosphate is rapid enough definitely to increase the amt. of serum Ca when these salts are administered orally in amts. equiv. to 0.2727 g. of CaO per kg. of body wt. Results with the relatively insol. salts such as CaCO_3 are inconst. The sol. salts simulate the insol. ones if given in amts. equiv. to less than 0.2727 g. of CaO. Ca lactate is preferable to CaCl_2 even though it must be given in greater bulk as it is less irritating to the gastric mucosa. Orally administered Ca salts control tetany by increasing the blood Ca level of parathyroid dogs. A. P. LOTHROP

Physiological effect of hot air baths. CORNELIA G. BENEDICT, F. G. BENEDICT AND E. F. DUBOIS. *Am. J. Physiol.* 73, 429-48 (1925).—The effects of exposing the nude human body to dry hot (85°) air on body wt., rate of metabolism, pulse, respiration and body temp. are noted. The large loss in body wt. is practically all H_2O rather than org. matter. J. F. LYMAN

The excretion of carbon dioxide by frog nerve. C. H. PARKER. *J. Gen. Physiol.* 8, 21-31 (1925).—Quiescent sciatic nerve of the frog discharges CO_2 at the av. rate of 0.00876 mg. per g. nerve per min. When steeped 1 min. in boiling H_2O , it discharges first at a low rate and in $1\frac{1}{2}$ hr. not at all. Degenerated sciatic nerve discharges at a slightly higher rate than normal nerve. Connective tissue discharges at a rate of 0.0097 mg. per g. per min. av. It is estd. that the strictly nervous components of a nerve have a rate of 0.008 mg. CO_2 per g. per min. The CO_2 production for stimulated sciatic nerve is 14% over quiescent nerve; corrected for the strictly nervous components the increase is 16%. This increase was not observed on stimulation of normal nerves after boiling, blocking or degeneration nor in stimulated strands of connective tissue. Cf. *C. A.* 19, 2523, 2986. CHAS. H. RICHARDSON

Metabolism under reduced atmospheric pressure. A. JAQUET. *Schweiz. med. Wochschr.* 55, 755 (1925); *J. Am. Med. Assoc.* 85, 1096.—On the basis of Ehrlich's theory that arsenicals are toxic only when the As is in the trivalent state, J. employed the min. lethal dose of quinquivalent arsenicals (atoxyl and Na cacodylate) as a means

to measure the reduction processes in the rabbit under various atm. pressures. Under a pressure corresponding to an altitude of 1800 m., the lethal dose of these arsenicals is reduced by 22 to 23%, as compared to the lethal dose at sea level. This proves that at an altitude which usually does not produce any subjective symptoms, the metabolic processes are altered.

Physiological action of ovarian fluid. W. J. BERESIN, W. W. PETROWSKY AND G. A. MALOFF. *Arch. ges. Physiol.* (Pflüger's) **209**, 170-6(1925).—Upon the frog heart ovarian fluid exerts a strong and protracted stimulating action, expressed by an increased amplitude, both systolic and diastolic. With the rabbit heart there is also, as a rule, an increased amplitude but in some instances, particularly when the heart first comes in contact with high concns. of the fluid, the amplitude is diminished. Upon the vessels of the frog liver the fluid is without obvious effect although it causes a constriction of the vessels of the rabbit ear. The fluid has a sensitizing effect in that it intensifies the action of minimal doses of adrenaline.

Physiology of intestinal motility. FRITZ SCHNELLER. *Arch. ges. Physiol.* (Pflüger's) **209**, 177-217(1925).—An analysis of the relationships between peristalsis and tonus under different conditions.

A preliminary study of the chemistry of post-mortem blood and spinal fluid. G. W. PUCHER AND LILLIAN A. BURD. *Buffalo General Hospital Bull.* **3**, 11-3(1925).—A comparative analysis of post-mortem blood and spinal fluid is presented. The greatest differences are found in the uric acid, amino acids and CO_2 . The quantities in the spinal fluid are always smaller than those in the blood. The detn. of urea N, sugar and creatinine in post-mortem spinal fluids may be of value in confirming pre-mortal blood chemistry.

Relationship of the chemical constituents of blood and cerebrospinal fluid. L. S. KUBIE AND GERTRUDE M. SHULTS. *J. Exptl. Med.* **42**, 565-91(1925).—If due allowance is made for the slow rate of elaboration of cerebrospinal fluid and for the time that it takes for newly formed fluid to emerge from a needle in the cisterna, the amt. of sugar, chloride and non-protein N in the fluid seems to follow in a general way their concns. in the blood serum. It is equally evident, however, that for any substance other factors besides its concn. in the blood stream play a part in its distribution between blood and cerebrospinal fluid. Many analytical data are given for samples from humans and dogs.

Urobilin physiology and pathology. V. The relation between urobilin and conditions involving increased red cell destruction. ROBERT ILMAN AND P. D. McMASTER. *J. Exptl. Med.* **42**, 619-40(1925); cf. *C. A.* **19**, 2530.—Animals rendered urobilin-free by the collection of all the bile from the intubated, uninfected common duct remain urobilin-free during and after extensive blood destruction caused by intravenous injections of distd. H_2O , as also after reinjections of the animal's own blood, hemolyzed *in vitro*. No urobilin appears in the bile, urine or feces of animals so intubated when blood destruction has been caused by Na oleate, or by an agent, toluylenediamine, which damages the liver as well as the blood. On the other hand, when bile flow into the intestine is uninterrupted, urobilinuria occurs during blood destruction caused in any of the ways mentioned and it parallels, both in severity and duration, the destructive process. Merely increasing the amt. of bilirubin within the intestines of healthy dogs by feeding urobilin free bile will lead to marked urobilinuria. The effects of other physiol. and pathol. conditions are discussed. The results indicate that urobilinuria, occurring during blood destruction, is primarily the result of an increased excretion of bilirubin from which, in turn, an unusually large quantity of urobilin is formed within the intestine. The liver fails to remove from the portal blood all of the latter pigment which is reabsorbed and consequently some of it reaches the kidneys and urine.

Study of the metabolism of salicylic acid. E. G. HOLMES. *J. Pharmacol.* **26**, 297-314(1925).—After the ingestion of salicylates by a normal individual on a mixed diet, salicylic acid was isolated from the urine, and identified (soly., NH_2 and total N content and m. p.). For doses of Na salicylate of from 2 to 5 g., the salicylic/salicyluric ratio is constant at the value of 40/60. This ratio, after the ingestion of 1.5 synthetic salicyluric acid, reaches the value of 8/92. The distn. method for the detn. of total salicyl in urine, as described by Hanzlik, is not satisfactory when solns. of pure salicyluric acid in urine are employed. No evidence has been found for the destruction of salicylic acid in the body. No salicylglucuronic compds. were excreted in these expts.

C. J. WEST

G—PATHOLOGY

H. GIDEON WELLS

Diphtheria toxin-antitoxin titration by Ramon method for practical application. O. R. POVITZKY and E. J. BANZHAF. *Proc. Soc. Exptl. Biol. Med.* **22**, 11-3(1924).—The Ramon method depends upon a flocculation which occurs in toxin-antitoxin mixts. of certain proportions, and is absent in an excess or deficiency of either ingredient. 2.5 cc. of a potent stable toxin, titrated for its L+ and flocculation values, were placed in each tube, and varying amts. of undil. serum were added. The tubes were incubated at 50°. The first tube to flocculate indicated a nearly neutral mixt. and from this the antitoxin value was calculated. The results agreed closely with guinea pig tests.

C. V. B.

A chemical study of tuberculin. J. H. MUELLER. *Proc. Soc. Exptl. Biol. Med.* **22**, 209-11(1925).—Old tuberculin prepd. from glycerol infusion broth gives a pptn. reaction with good immune sera in a diln. of 1-1000, and a skin test in tuberculous guinea pigs in a diln. of 1-50 to 1-100. After several pptns. with alc., AcOH pptd. a substance which gave a powerful skin reaction in high diln. but a weak pptn. reaction. A tannic acid pptn. gave no skin reaction at the ordinary diln. but gave a pptn. reaction at a diln. of 1-40,000. By the use of synthetic media and fractional alc. pptn. followed by dialysis, a substance was obtained which gave a pptn. reaction in a diln. of 1-1,000,000. This material in a diln. of 1-100 gave a doubtful or negative skin test.

C. V. B.

A spasm-inciting substance in the sputum during asthmatic attacks. J. HARKAVY. *Proc. Soc. Exptl. Biol. Med.* **22**, 225-6(1925).—Sputa were obtained from 8 cases of bronchial asthma during the height of the attack. An alc. ppt. was dissolved in Tyrode soln. and tested on strips of smooth muscle from cat intestine suspended in Tyrode soln. The ext. contained a substance which stimulated unstriated muscle to sustained contraction. Negative results were obtained from cases of pulmonary tuberculosis, bronchiectasis, normal individuals and from asthmatic patients in the interval of attacks.

C. V. B.

The condition of enzymes during recurrent typhus. A. A. GUERQUÉ. *J. physiol. path. gén.* **23**, 617-24(1925).—Blood enzymes show great variations, protease and catalase each showing a sp. type curve. Between the 2 there is often an antagonism, the value for each depending on the gravity of the infection. With the complication of lobar pneumonia a different type of curve is developed for catalase.

A. T. CAMERON

The cerebrospinal fluid in lead poisoning. C. V. WELLER and AILEEN D. CHRISTENSEN. *Arch. Neurol. Psychiatry* **14**, 327-45(1925).—The cerebrospinal fluid in Pb-meningo-encephalopathy is clear, sterile and shows increased pressure, cells, globulin content, and probably sugar. Fairhall's improved hexanitrite test apparently has demonstrated passage of Pb in the cerebrospinal fluid of Pb-poisoned rabbits.

A. T. C.

Cerebrospinal fluid sugar. F. FREMONT-SMITH and MARY E. DAILEY. *Arch. Neurol. Psychiatry* **14**, 390-5(1925).—Spinal fluid, as well as blood plasma, contains reducing substances other than glucose, which disappear on hydrolysis, and may amt. to more than 10% of the total "sugar." The hyperglucemia following sugar-tolerance tests is reflected in the lumbar spinal fluid only after a latent period following the administration of glucose, by which time the blood sugar may have fallen below the cerebrospinal fluid value. Hence no statement can be made at present as to the normal ratio of spinal fluid sugar to blood sugar, nor can the normal limits of the former be stated. Values for it above 80 mg. occur in many conditions, and are usually associated with hyperglucemia, which is not uncommon in cerebral conditions. In absence of hypoglycemia values below 50 mg. nearly always indicate an acute infection of the meninges. Values should be detd. after an over-night fast, and compared with coincident blood sugar.

A. T. CAMERON

The human cerebrospinal fluid in the general system and metabolic diseases as in nephritis, diabetes, etc. B. J. ALPERS. *J. Nervous Mental Dis.* **62**, 265-78(1925).—A review, chiefly from the literature.

A. T. CAMERON

Cerebrospinal fluid chlorides. F. FREMONT-SMITH and MARY E. DAILEY. *Arch. Neurol. Psychiatry* **14**, 509-12(1925).—A general paper of variations in disease, giving no statement of actual results.

A. T. CAMERON

Transient glucosuria following scorpion sting. H. E. KING FREITZ. *Brit. Med. J.* **1925**, II, 294.—Three cases following (Trinidad) scorpion stings showed glucosuria (0.2 to 0.6% glucose) for 2 or more days, although the acute symptoms subsided after KMnO₄ treatment.

A. T. CAMERON

Tubercle formation from the injection of toxic substances. RUDOLF JAFFE. *Z. Tuberk.* **40**, 284-5(1924).—By injecting CHCl₃ exts. of tubercle bacilli, identical results

were obtained to those of Guillery (*Z. Tuberk.* 38, 1(1923)), indicating the toxic origin of tuberculous changes. Ray and Shipman were able to obtain tuberculous changes from defatted tubercle bacilli which Jaffe could not corroborate. Morse and Schott found typical tubercles with giant cells after the injection of alc. exts. of tubercle bacilli, but not from ether exts.

H. J. CORPER

Reply to remarks of Jaffe on tubercle formation after the injection of toxic substances. H. GUILLERY. *Z. Tuberk.* 40, 286(1924).—G.'s expts. were misunderstood by Jaffe. Proof is lacking for toxic substances from tuberculous structures acting upon the tuberculous focus. The remote action of the living bacillary focus is not related to Jaffe's expts.

H. J. CORPER

The significance of serum lipase in pulmonary tuberculosis. E. HENSCHKE AND H. ZWERG. *Beitr. klin. Tuberk.* 58, 324-8(1924).—The investigation for serum lipase in tuberculosis and other infectious diseases revealed diminished values, and there is no parallel between the lipolytic power (dtd. by means of the tributyrin method) of the serum and immunity. The findings of Kellert and Frisch (*Beitr. klin. Tuberk.* Vols. 43, 47 and 48) that all cases of cachexia with pulmonary tuberculosis revealed low lipase titers were corroborated, while cases in good general condition revealed a normal or only slightly reduced value. There seems to be a close relationship between the lipolytic power of the serum and the cachexia. This was borne out by the low values found in other cachectic conditions.

H. J. CORPER

Auto serum reaction in tuberculosis. A. V. v. FRISCH. *Beitr. klin. Tuberk.* 58, 280-92(1924).—A satisfactory explanation of the nature of the substances occurring in the blood which after intracutaneous injection caused papule formation could not be given. Since especially in those cases with most marked toxic symptoms there occur no reactions, it is believed that neither the toxins nor endotoxins occasion the toxic symptoms in severe phthisis, but it is due to the decomposition products of the tuberculous tissues.

H. J. CORPER

The diagnostic significance of the alizarin test for protein in the sputum. GEORG ZÜHLSDORFF. *Z. Tuberk.* 40, 449-52(1924).—The alizarin test for protein in the sputum is not specific for tuberculosis; the number of positive reactions increase with the severity of the disease. The reaction is negative in 30% of advanced cases of pulmonary tuberculosis. It has no differential diagnostic significance.

H. J. CORPER

The presence of heterogeneous antigens in denucleated erythrocytes. K. A. FRIEDE AND F. T. GRUNBAUM. *Klin. Wochschr.* 4, 1778-9(1925).—Rabbits, when injected with either sheep or cat erythrocytes, engender hemolysins against both cat and sheep erythrocytes. Rabbits, when injected with sheep erythrocytes, engender hemoagglutinins against cat erythrocytes. Cat erythrocytes, injected, do not engender heterogeneous hemoagglutinins.

MILTON HANKE

Hyperglucemia after ingesting levulose or carbohydrate-phosphate. J. ABELIN AND E. GOLDENER. *Klin. Wochschr.* 4, 1733(1925).—Ingestion of levulose does not lead to a significant hyperglucemia in normal individuals. A hyperglucemia is produced in diabetics; but not when insulin is given simultaneously. Levulose does not reduce the hypoglucemia that results from insulin poisoning. If a thyroid prepn. is fed for some time before the levulose is ingested, hyperglucemia is obtained. Phosphate, when ingested with glucose or levulose, enhances the rate of occurrence of hyperglucemia (no thyroid). Cf. following abstr.

MILTON HANKE

Insulin hypoglucemia. J. ABELIN AND E. GOLDENER. *Klin. Wochschr.* 4, 1777-8(1925).—Ingested Na_2HPO_4 prevents hypoglucemia when small amts. of insulin are injected and markedly reduces the hypoglucemia that normally follows large doses of insulin. The symptoms of malaise also are absent in the latter case.

M. H.

The potassium content of blood and the potassium-calcium ratio in essential hypertonia. E. KYLIN AND G. MYHRMAN. *Klin. Wochschr.* 4, 1870(1925).—The normal K/Ca ratio is 1.7-2.15. In cases of essential hypertonia this ratio is 2.08-2.97. The absolute K values are slightly increased, the Ca is decreased. The adrenaline reaction is intimately associated with the Ca and K content of the blood. When the Ca content is high, the rise in blood pressure, induced by adrenaline, is augmented; when the K content is high, the blood pressure effect of adrenaline is decreased.

M. H.

Significance of acids, formed by fermentation, for the pathogenesis of the digestive disturbances of infants. WERNER CATEL. *Klin. Wochschr.* 4, 1867-8(1925).—The ratio of lactic acid to volatile fatty acid production on a milk medium is 10-1 (enterococcus), 1-10 (*B. coli*) and 1-3 (*B. bifidus*). Lactic acid and its Na salt do not irritate the intestinal mucosa. Acetic acid and the other volatile fatty acids and their Na salts irritate the mucosa cells. The large intestine is less irritable than the small intestine.

Intestinal disturbances, in infants, may be due to an abnormally large production of volatile fatty acids by the intestinal microorganisms. MILTON HANKE

Is an incubation period, after preparation, necessary for the production of passive anaphylaxis? R. FRIEDBERGER AND S. SEIDENBERG. *Klin. Wochschr.* 4, 1823-4 (1925).—A slightly pptg. active antiserum can be prepd. by injecting guinea pigs with egg albumin. When this antiserum is injected into a normal guinea pig, passive sensitization occurs immediately, and a typical anaphylactic reaction is obtained when the antigen is injected within 5 min. This would indicate that fixation of the antibody to the cells is not necessary for an anaphylactic reaction. The foreign protein introduced in large quantity when rabbit antiserum is injected into guinea pigs may be responsible for the incubation period that is necessary before the passive sensitization can be demonstrated. MILTON HANKE

The hexosephosphoric acid content of blood in the normal and diabetic organism and the effect of adrenaline and insulin on its concentration. HEINZ LAWACZECK. *Klin. Wochschr.* 4, 1858-61 (1925).—The Ba salt of hexosephosphoric acid (H. P. A.) is insol. in water; hence H. P. A. can be sepd. from glucose, in a blood filtrate, with $\text{Ba}(\text{OH})_2$. The hexose content of the ppt. is then estd by reduction. The normal H. P. A. content of blood is about 1 mg. %; but it may vary from 0.66 to 2.0 mg. %. Administration of adrenaline gives a marked rise in blood sugar and a simultaneous decrease in H. P. A. Fifteen min. after the injection the H. P. A. begins to rise rapidly. Its concn. soon exceeds its pre-insulin value. Administration of insulin lowers the blood sugar and elevates the H. P. A. Glucose, as such, cannot be fixed to the body cells. Fixation occurs as hexosephosphoric acid. Adrenaline leads to the conversion of glycogen and of H. P. A. into glucose. The concn. of blood sugar rises in consequence. Insulin is involved in the conversion of glucose into H. P. A. The latter becomes fixed to the body cells and the blood sugar decreases. From this it is clear that adrenaline and insulin are really antagonistic; each tends to undo the work of the other. A balance normally exists, in the body, between these two substances and their opposing forces. The subcutaneous application of adrenaline leads to a hyperadrenalinemia and upsets the balance that exists between adrenaline and insulin. The organism reacts against this upset by inhibiting the suprarenal glands and stimulating the pancreatic glands. After the adrenaline depot has been exhausted, the organism continues its reaction for a short time which leads to an *insulin* effect, namely, an elevation of H. P. A. above normal. The effect of an insulin injection is the reverse of the above. There are two kinds of diabetics; those that react normally toward insulin (with an elevated H. P. A. and a reduced blood sugar) and those that react paradoxically (with a reduced H. P. A.). The first type represents cases in which the activity of the pancreatic cells is deficient; they can be successfully treated with insulin. In the second group a pathological balance exists between insulin and adrenaline in favor of the adrenaline. The organism depresses the pancreatic glands excessively and reacts rapidly and powerfully to keep the balance in favor of the adrenaline. An injection of insulin leads, therefore, almost immediately to a marked stimulation of the suprarenal glands with a consequent *adrenaline* effect in place of an *insulin* effect. The prognosis in these cases is always bad. MILTON HANKE

Use of the Rabl precipitation method with bones from children afflicted with rickets. RICHARD BÖHMIG. *Klin. Wochschr.* 4, 2010-2 (1925).—Immerse the bones in a neutral, satd. soln. of $(\text{NH}_4)_2\text{C}_2\text{O}_4$ for 48 hrs. This ppt. the sol. Ca as crystals of CaC_2O_4 . Soak in H_2O for 24-48 hrs. Dissolve out the Ca that had been pptd. *in vivo* by immersing the bones in formic acid. Exam. the washed prepn. histologically. A detailed histological description is given (no pictures). MILTON HANKE

Clinical evaluation of the trypanocidal function of the liver. FRIEDRICH MÜNTER. *Klin. Wochschr.* 4, 1967 (1925).—Normal serum—0.2 cc. per 20 g. body wt.—is fully protective against a trypanosome infection in mice. The protective action of the serum of hepatopathics, with a diffuse destruction of the parenchyma of the liver, is inversely proportional to the degree of the destruction. Icterus may or may not influence the trypanocidal action of the serum. MILTON HANKE

Alimentary leucocytosis and leucopenia. ERNST WOLLHEIM. *Klin. Wochschr.* 4, 1960-2 (1925).—A local increase in the concn. of Ca or H ions leads to a local leucocytosis. An increase in K or OH ions leads to a local leucopenia. MILTON HANKE

Ossification. FRITZ EICHMOLTZ. *Klin. Wochschr.* 4, 1959-60 (1925).—A bibliographical review of the recent work following the discovery, by Robison, of an enzyme, in bone, that can convert org. phosphates into inorg. phosphates. M. H.

Maximal hypoglycemia without the use of insulin. E. GEIGER AND L. SZIKTES. *Klin. Wochschr.* 4, 1912-4 (1925).—Splanchnicotomy, in rabbits, leads to hypothermia.

Injection of coli toxin or atropine produces a pronounced hypoglucemia; the blood sugar is reduced to 0.03–0.01%. Cramps may not occur for hours. When they do occur, the animals die unless treated. Adrenaline or glucose removes the cramps promptly. Adrenaline still further decreases the blood sugar to 0.007%; but the animals do not die. Glucose raises the body temp.

MILTON HANKE

The chemistry of the production of an epileptic attack by forced respiration. F. MAINZER. *Klin. Wochschr.* 4, 1918(1925).—Injection of NaCl promptly initiated an epileptic attack in one patient. Voluntary forced respiration, which also called forth an attack, led to a 4% increase in plasma chlorides; the total Cl content of the blood remained unchanged. The possible connection is obvious. An injection of glucose does not lead to an attack. NaOAc, when injected, does elicit an attack. In this case the acetate ion is considered to be the irritating substance

MILTON HANKE

Improvements in blood investigations. HUGO SELHEIM in collaboration with LÜTTGE, v. MERTZ AND BERGER. *Klin. Wochschr.* 4, 2049–53(1925).—Two new refinements for the methods of C. A. 19, 2079, are described. The serum to be tested is mixed, and allowed to react for 30 min. with a specially prepd. ninhydrin-negative organ extract (details of prepn. not given) supplied by the firm of A. Wolff. The liquid is boiled to coagulate the proteins, filtered and the filtrate tested with ninhydrin. Not only can pregnancy be diagnosed with an accuracy of 98% but the sex of the fetus can also be detd. with similar accuracy. The method should also be suitable for the diagnosis of malignancy, with properly prepd. organ exts. and may prove suitable for the diagnosis of infectious diseases. The detn. can be completed in 45 min. *Second process.*—Evap. to dryness 1 cc. of the specially prepd. organ ext. Dissolve the residue in 1 cc. of the serum to be tested. After 30 min. add 10 cc. of 95% alc., filter, and to 4 cc. of the filtrate add 0.025 N HCl until a cloud appears. Less acid is required to produce a cloud in positive than in normal serums. This method has not been very thoroughly tested for specificity.

MILTON HANKE

Influence of protein on the ketone body elimination in severe diabetes. S. J. THANNHAUSER AND W. MARKOWICZ. *Klin. Wochschr.* 4, 2093–9(1925).—Severe diabetics with a low sugar tolerance catabolize tyrosine, leucine and phenylalanine with production of ketone bodies. The output of ketone bodies is never greater than, but may be equal to, the amt. that could be theoretically produced from the quantity of amino acid ingested. Ketone bodies could not, theoretically, be produced from glycine or alanine and these amino acids, when ingested, have no effect upon the existing ketonuria. From this it is clear that the specific dynamic action of protein, which is shared by the amino acids, is not responsible for the ketonuria. Diabetics with an improving sugar tolerance catabolize all of the amino acids completely. Ketone bodies are not formed

MILTON HANKE

Influence of insulin on tar carcinoma. H. D. v. WITZLEBEN. *Klin. Wochschr.* 4, 2115(1925).—Daily injections of insulin protect rabbits against tar carcinoma.

MILTON HANKE

Acetone body concentration in blood in cases of toxicosis of pregnancy. O. BOKELMANN AND A. BOCK. *Klin. Wochschr.* 4, 2158(1925).—Blood normally contains about 30 mg. of acetone bodies (calcd. as acetoacetic acid) per 1000 cc. The av. figure during normal pregnancy is 40 mg. In pregnancy with albuminuria the value is 54 mg. Severely intoxicated patients average 65–75 mg. In pre-eclampsia and in eclampsia the av. figure is 65 mg.

MILTON HANKE

Two different types of phenomena by the specific antigen-antibody reaction that occur in vitro between a monogenic anti (protein) serum and its homologous antigen. E. FRIEDBERGER AND T. IKEDA? *Klin. Wochschr.* 4, 2140–51(1925).—When a dil. soln. of an antigen is carefully superimposed upon an antiserum in a small test tube, two distinct rings are formed, sepd. by a clear band. The lower ring consists of coarse, heavy, protein flocculi, insol. in ether, that settle gradually to the bottom of the tube. The upper ring is composed of a very fine, light ppt., sol. in ether, that stains intensely red with sudan III and reduces osmic acid, and that gradually diffuses upward through the antigen layer until the entire upper layer has become uniformly cloudy. If the antigen and the antiserum are extd. with ether before performing the ring test, or if just the antigen is extd. with ether, a double ring is not formed; only the heavy protein ppt. is obtained. The upper, "lipoid" ring is the one that is obtained when a foreign antigen is superimposed upon an antiserum. Double ring formation occurs best at 0°. Sera that have been preserved for some time with phenol still show the double ring phenomena. Rabbit antisera against protein from man, sheep, steer, horse, pig, dog, chicken and cat were used in the above expts. Guinea pig antisera behave similarly. Heterogeneous antigens give only one ring, namely, the lipoid ring. MILTON HANKE

Lactic acid excretion in carcinoma. K. GLAESSNER. *Klin. Wochschr.* **4**, 1868-9 (1925); cf. *C. A.* **19**, 3534.—The artificial production of carcinoma and enchondroma in rats is followed by a metabolic disturbance. The intravenous injection of glucose is followed by an excretion of lactic acid in amts. up to 1% of the animals' body wt. The animals have lost the faculty of oxidizing lactic acid. MILTON HANKE

Studies on the nature of the immunity reaction. I. An experimental study of pneumococcal immunity. R. R. ARMSTRONG. *Proc. Roy. Soc. (London)* **98B**, 525-44 (1925).—Measurement may be made, with a high degree of accuracy, of the protective power of sera, prepd. by immunization of rabbits with pneumococcal vaccine, against measured doses of living pneumococcal cultures, with mice as test animals. Immunity is produced in a characteristic manner after exptl. inoculation in the rabbit, or the natural stimulus of lobar pneumonia in man. An inductive phase of 3 to 5 days is followed by a rapid outpouring of protective antibodies into the blood serum at an increasing rate corresponding to a geometric progression, the max. concn. of antibodies being attained on the 8th day after inoculation. During the resulting phase of const. high immunity, the serum probably is satd. with immunizing substances. The resistance of an immunized animal to the homologous living pneumococcus coincides with the appearance of the antibodies in the blood serum. Provided neither excessively large nor excessively small doses of vaccine be used, the following rules hold true: The smaller the dose, the less complete and shorter the phase of induction; the earlier the appearance of immunity, the sooner the attainment of max. immunity, and the shorter the period of active immunity. The max. immunity attained is proportional to the size of the dose. Small doses (less than 5000 organisms) have no antigenic effect on the rabbit, being destroyed by the natural nonspecific mechanisms of the body. Excessive doses cause prolonged postponement of immunity, although antibodies finally appear in the serum. II. *Ibid.* 545-56.—Administration of protective antibodies after administration of their antigen causes postponement of the active immunity without any conspicuous decrease in its intensity. Administration of antigen to an animal previously passively immunized by intravenous administration of the corresponding immune serum gives rise to a marked decrease in, but no postponement of, the active immunity. On administration of a sensitized vaccine (equiv. doses of antigen and its antibodies) the greater portion of the latter are liberated and rapidly impart a slight degree of immunity; the antigen then gives rise to the development of active immunity in the same manner as a raw vaccine. However, this immunity is delayed, and is less intense than that produced by an equal dose of raw vaccine. JOSEPH S. HEPBURN

The role of the ether-soluble constituents of serum in certain serological reactions. P. HARTLEY. *Brit. J. Exptl. Pathol.* **6**, 180-96(1925).—The ether-sol. constituents were removed from various sera by the method of Hary and Gardiner (*J. Physiol.* **40**, lxviii(1920)). Specific pptn. does not occur when both antigen and antiserum, which have been freed from the ether-sol. constituents which they normally contain, are mixed together. The union of diphtheria toxin and diphtheria antitoxin is independent of the ether-sol. constituents occurring in antitoxic serum. Flocculation of neutral or nearly neutral mixts. of toxin and antitoxin (Ramon's reaction), however, is dependent upon these constituents. The agglutination of bacteria by a specific serum, and the hemolysis of red cells by a specific serum, are independent of the ether-sol. constituents of the serum. The complement-fixing property of syphilitic serum is associated with the ether-sol. constituents of the serum, since such sera after extn. react negatively in the Wassermann reaction. HARRIET F. HOLMES

Pathogenesis of edema. KL. GOLLWITZER-MEIER. *Z. ges. exptl. Med.* **46**, 15-39 (1925).—In edema fluid the concns. of HCO_3 and Cl are higher than in the blood serum and the concns. of K and Ca are lower. The Na content is usually but not always higher in edema, while the phosphate content seems evenly divided. The distribution of H, Cl, HCO_3 and perhaps Na ions between edema fluid and serum takes place according to the equil. law for membranes of Donnan (*C. A.* **6**, 1559). During an increase of edema there is a decrease of HCO_3 and Cl in the serum and an increase of Na and K, and during disappearance of the edema an increase of anions and decrease of cations. In normal persons the equiv. sum of the cations in the blood serum is always greater than the sum of the anions, because of the presence of negatively charged proteins and perhaps of other unknown anions. In an edematous patient this deficit of anions frequently varies from normal values on account of changes in the total proteins or in the protein fractions. From the concn. of H and Cl ions in the serum and edema fluid the potential of the membrane can be calcd. The serum is negatively charged in relation to the edema fluid. The potential becomes smaller as the difference of concn. of the ions

in serum and edema becomes less. Addition of NaCl or decrease of total protein in the plasma causes the potential to become smaller. Probably these changes are of importance for the colloidal condition and for the permeability of the capillary wall. It is probable that reversible changes of permeability may occur, permitting the passage of protein. The same conditions that lead to a difference in potential also reduce the osmotic pressure of the serum, that is, a lessening of the protein content and such changes in the protein fractions as lead to a deficit of anions and which in many cases are caused by the administration of NaCl.

HARRIET F. HOLMES.

The meaning of alterations in the calcium of the serum in fever. F. GLASER. *Z. ges. expl. Med.* 46, 65-72(1925).—Excluding pneumonia, in 33 febrile conditions alteration of Ca content of the serum was noted in over half of the cases when the Ca content of the serum was compared during and after fever. The hypocalcemia in pneumonia is due to the retention of Ca in the formation of the extensive fibrin masses of the pneumonic exudate and the release of this Ca on resolution of the pneumonia. In the other cases it is probable that the changes of Ca content brought about by fever are due to changes in tone of the vegetative nervous system and are similar to the changes in Ca content in functional neurosis which may be greatly altered by hypnosis. H. F. H.

Ammonium chloride acidosis. R. HOPMANN. *Z. ges. expl. Med.* 46, 73-93(1925).—Administration of NH_4Cl in 10 g. doses in normal persons sets free in the body, through breaking down of the salt, acid valences to an equivalent of 50-100% of the salt introduced. There is a marked increased excretion in the urine of Ca, but not of other cations. This loss of Ca through the urine is made up in part by an increased utilization of Ca from the intestinal tract and in only one case was there a slight Ca loss from the body as a whole. N metabolism and H_2O balance of the body were not altered by NH_4Cl acidosis. Oxidation was at first reduced but in the end in spite of repeated doses of NH_4Cl the intensity of O metabolism was not altered. H. F. H.

The importance of the cations, sodium, potassium and calcium, for the occurrence and treatment of nephritic edema. W. KEMPMANN AND H. MENSCHEL. *Z. ges. expl. Med.* 46, 111-20(1925).—Administration of Na as NaHCO_3 in nephritis with edema causes a retention of H_2O in the tissues with an increase in concentration of blood and urine. Only after large doses of alkali does the acid urine become alk. The K ion acts in a manner antagonistic to the Na ion and may be of therapeutic value. Administration of KHCO_3 leads to a hydremia and increased diuresis. The results with Ca are not decisive but CaCl_2 even in large doses seems to have no definite effect on the H-ion concn. of the urine. The Ca ion had no definite effect on albuminuria nor diuresis. H. F. H.

Kidney function in severe cases of diabetes. O. KLEIN. *Wiener Arch. inn. Med.* 10, 507-42(1925).—In severe diabetes the concn. power of the kidney is not affected and there may be polyuria with even a restricted intake of fluid. The diln. power of the kidney is also not affected. The water test often shows a delay of H_2O excretion or a retention of H_2O . The extrarenal excretion of H_2O is probably dependent on changes in the colloidal binding of H_2O in the tissues, brought about by changes in carbohydrate metabolism. Urea is excreted promptly when given. NaCl may be excreted but is often retained, and without simultaneous retention of H_2O . In severe diabetes there seems to be a reciprocal relation in the excretion of glucose, urea and NaCl. The kidney does not seem able to secrete large amts. of these substances at one time and this relative insufficiency may account for the raised threshold value for glucose in cases of long standing.

HARRIET F. HOLMES

The specific viscosity of the blood serum in joint diseases. L. KAUFTHIL AND A. SIMÓ. *Wiener Arch. inn. Med.* 11, 191-200(1925).—The specific viscosity of the blood serum is 0.96 to 0.99 in normal persons. In joint disease it increases in proportion to the extent of tissue waste and the severity of the inflammatory processes. It is of normal value in arthritis urica, slightly higher in arthritis deformans and secondary chronic polyarthritis and highest in primary chronic polyarthritis and tuberculous joint lesions.

HARRIET F. HOLMES

A specific precipitating substance from tubercle bacilli. P. P. LAIDLAW AND H. W. DUDLEY. *Brit. J. Exptl. Pathol.* 6, 197-201(1925).—Glycogen has been isolated from tubercle bacilli, also a carbohydrate complex of the nature of a gum. This gum gives specific pptn. with immune serum. The gum from tubercle bacilli has no relation to tuberculin and is not a true antigen, since it fails to induce the formation of antibodies. It is probable that for the production of this particular antibody, giving specific ppts. with tubercle gum, stimulation by a protein carbohydrate complex is required, and that when this antibody is formed pptn. can occur with the whole mol. or with either part separately.

HARRIET F. HOLMES

Variations in the blood and urine diastase contents in relation to measles. I.

COHEN. *Brit. J. Exptl. Pathol.* **6**, 173-9(1925).—The output of diastase in the urine varies greatly, with an immediate rise after a meal. The blood diastase remains at a constantly low level, despite marked changes in urinary diastase content. It is probable that diastase is irregularly absorbed from the gut and then is excreted as completely as possible from the blood. Examin. of isolated specimens of urine for clinical purposes would seem to yield very unreliable information. On the other hand the relative constancy of the blood diastase content renders any special precautions with regard to meals unnecessary.

HARRIET F. HOLMES

The chemical composition of gallstones in Dutch India and their diagnosis by means of Röntgen rays. C. D. DE LANGEN. *Geneeskundig Tijdschr. Nederl. Indie* **65**, 90-102 (1925).—Cholelithiasis is rare in Dutch India. Cholesterol and cholesterol-bilirubin stones occur very rarely, bilirubin-CaO stones (I) and Ca bilirubinate stones (II) frequently, bilirubin (III) stones most frequently. Unlike cholesterol stones I, II and III and particularly II give distinct Röntgen shadows. The cholesterol content of the blood serum of the natives, especially the poor population, is 25-50% lower than that of Europeans and the wealthy natives. Natives kept 1 week on a diet rich in cholesterol show a 50% increase of the blood cholesterol. The prevalence of pigment stones demonstrates the role of infection in the etiology of gallstones in contrast to Naunyn's theory. Although it is admitted that the cholesterol content of the diet is not the only factor controlling cholesterol metabolism, yet the importance of diet is evident. It may be emphasized in this connection, that diabetes and chronic nephritis are also rare among the natives, who live mainly on rice and vegetables.

MARY JACOBSEN

The carbohydrate metabolism of tumors. II. Changes in the sugar, lactic acid and carbon dioxide-combining power of blood passing through a tumor. C. F. CORI AND GERTY T. CORI. *J. Biol. Chem.* **65**, 397-405(1925); cf. *C. A.* **19**, 2850.—Blood drawn from the right and left wing vein of normal chickens contains the same amts. of sugar and lactic acid and has the same CO₂-combining power. Blood which has passed through a tumor growing on one wing contains an av. of 23 mg. less of sugar and 16.2 mg. more of lactic acid than blood which has passed through the tissues of the normal wing, indicating active glucolysis. Upon satn with alveolar air the plasma from the tumor blood showed 3.7 vols. % less CO₂ than that from the normal side but when collected under oil it contained an av. of only 0.7 vol. % less CO₂ than the normal plasma.

A. P. LOTHROP

Urea tests of renal efficiency. I. I. M. RABINOWITCH. *J. Biol. Chem.* **65**, 617-22(1925).—"When urea was administered by mouth to normal individuals, previously restricted from fluids for at least 12 hrs., and tests showing polyuric responses, above the rate equal to the min. value of the 'augmentation limit' (2.5 l. per 24 hrs., the max. urine vol. output necessary to produce the max. rate of urea excretion) were discarded, the coeff. of variation in case of the factor, U/B , was practically identical with that of the const., $D/B\sqrt{VW}$. Under the same set of conditions a parallelism was also noted in 40 cases of albuminuria. Since urine vol. output is essential in calcg. the const. and is not taken into consideration in the calcn. of the factor, and in view of the above observations, its effect on urea excretion is practically negligible under the conditions described. Excretory ability of the kidneys thus appears to be the predominating factor influencing the value of the ratio U/B . The ratio has, therefore, a sound basis as a test of renal efficiency.

A. P. LOTHROP

Variations in blood sugar in relation to operation on the thyroid gland. C. C. LUND AND E. P. RICHARDSON. *Arch. Surg.* **11**, 171-9(1925).—There is a rise in blood sugar after hyperthyroid operations similar to that in other patients. No case of hypoglycemia occurred. There was no emotional hyperglucemia before operation. Treatment should maintain the supply of glucose.

JOHN T. MYERS

The excretion of water, urea and chlorides in experimental oxalate nephritis. J. S. DUNN AND N. A. JONES. *J. Path. Bact.* **28**, 483-506(1925).—When urea retention has been established in the tubular nephritis produced by oxalates it is possible to secure a decrease in urea retention by inducing a water diuresis. Extra chloride is excreted with the urea, suggesting that urea like chloride is excreted in the glomerular filtrate. Urea retention in this nephritis is explained on the theory that the damaged tubule cells are unable to prevent the indiscriminate reabsorption of glomerular filtrate with urea from the tubules into the connective tissue and vessels of the kidney.

J. T. M.

Cholesterol in health and disease. A critical review. J. M. H. CAMPBELL. *Quart. J. Med.* **18**, 393-422(1925).—There is a bibliography of 164 titles.

J. T. M.

The action of sensitized antigen in the production of specific and isophile hemolytic immune body. TSUNENORI IJIMA. *J. Path. Bact.* **28**, 397-406(1925).—Sensitization of antigen leads to a neutralization of antigenic power, since the amt. of immune body

produced is infinitesimal compared to that in controls with unsensitized antigen. A slight temporary increase of immune body soon after the injection of sensitized antigen is accounted for by the dissociation of injected antigen and antibody. J. T. M.

The classification of (common) salt by its iodine content, and the use of iodine in combating goiter. MICHAEL RÓZSA. *Kali* 19, 313-5(1925).—Statistics covering the distribution of goiter in Austria and Hungary, and of corresponding (local) concns. of I in the water supply, salt used and milk supply, are given. Legal requirement of 3 mg. KI per kg. salt for domestic consumption is recommended. WM. B. PLUMMER.

The blood glucose curve in head injuries. E. C. DAVIDSON AND C. I. ALLEN. *Bull. Johns Hopkins Hosp.* 37, 217-23(1925).—Such head injuries as fracture of the skull and concussion of the brain are followed by a profound but temporary derangement of carbohydrate metabolism; this seems to be similar to the sugar puncture reaction of Claude Bernard. The av. fasting blood sugar in fractures and concussion was within normal limits. The av. blood sugar at the end of 15 min. was higher in persons with concussion of the brain than in normal individuals, and this curve fell to fasting level more slowly. The curve was higher in fractured skulls than in concussion of the brain, and the fall to fasting level slower. The curve was more striking according to the seriousness of the injury G. F. REDDISH

Role of epithelium in experimental immunization. HENRY SEWALL. *Science* 62, 293-9(1925); cf. *C. A.* 9, 3288; 10, 2471.—When a small quantity of blood serum is dropped into the nose of a guinea pig the serum is adsorbed by the mucous membrane and, after a definite period of incubation, the animal can be shown to have become profoundly changed. Depending upon the no. of instillations, the interval between them and, especially, the quantity of serum instilled, the animal becomes either highly hypersensitive or strongly resistant, to a toxic injection given by the vein. This resistance withstands a considerable series of increasing toxic injections and is strengthened with the lapse of time, contrary to the state of tolerance produced by traumatic methods. It is inferred that the absorption of foreign protein by the nose causes the formation of 2 different antibodies. One of these is allergic and excites to anaphylaxis; the other is protective and leads to true immunity. The relative amt. of either antibody can be regulated by modifying the amt. of the serum instilled. Added to a state of general allergy it is easy to produce, in the guinea pig, a special sensitization of the respiratory app. which leads, under appropriate stimulation, to attacks resembling bronchial asthma in man. The evidence indicates that the living epithelium mediates between foreign protein and the organism in a way to favor specifically the elaboration of true immunity. L. W. RIGGS

Vital staining of inoculated tumors with acid dyes. D. ENGEL. *Z. Krebsforschung* 22, 365-72(1925).—Many inoculated tumors take as vital stains several acid dyes of the triphenylmethane group (fuchsin S, red violet, light green and isamine blue). This is true for the Jensen-tumor and mouse sarcoma, but not for the rat carcinoma. The coloring occurs in the living tumor cell and not in the necrotic cells as claimed by Karczag, Tischler and Barok. F. B. SEIBERT

Influence of alkali in hemolysis experiments on drug extracts (KARSMARK, KOFLER) 17.

H—PHARMACOLOGY

ALFRED N. RICHARDS

The action of ammonia upon the lungs. A. A. HORVATH. *Proc. Soc. Exptl. Biol. Med.* 22, 199-200(1924).—Rabbits and guinea pigs were exposed for long periods in atms. contg. 1.5, 0.5, 0.25 and 0.15 cc. of NH_3 per l. Guinea pigs tolerated 0.15% of NH_3 without apparent ill effects, but 0.25% caused catarrhal bronchopneumonia and its complications. Rabbits were more resistant. Intravenously, NH_4OH caused changes in the lungs similar to anaphylactic shock. C. V. B.

The treatment of malaria by novarsenobillon. H. E. WHITTINGHAM. *Proc. Roy. Soc. Med.* 18, War Sect., 23-32(1925).—Novarsenobillon compares very favorably with quinine in the treatment of benign tertian malaria. (Discussion, included, was adverse.) A. T. CAMERON

The therapeutic effect of light. W. E. DIXON, C. E. M. JONES AND G. H. LANCASHIRE. *Brit. Med. J.* 1925, II, 499-504.—A series of papers followed by a discussion and dealing especially with local action, general action, sp. action, heliotherapy, artificial light treatment and phototherapy in dermatology. A. T. CAMERON

Researches on the peripheral circulation of man. VI. Vascular action of adrenaline, atropine and amyl nitrite in normal man. D. DANIÉLOPOLU AND A. ASLAN.

J. physiol. path. gén. **23**, 572-81(1925).—Adrenaline produces on the peripheral circulation, in av. doses, a short phase of vasoconstriction (sometimes absent), then vasodilatation, followed by constriction, and finally by dilatation. The results can all be explained by interrelations between the abdominal and peripheral action, and the changing concn of adrenaline in the circulation. The action of atropine on blood vessels is similar to its action on other tissue with autonomic innervation. Amyl nitrite causes first vasoconstriction (passive) followed by vasodilatation. **VII. Action of atropine, adrenaline and amyl nitrite on the oculo-vascular reflex.** D. DANIELOPOLU AND A. ASLAN. *Ibid* 606-16.—A physiological study. A. T. CAMERON

Diabetes in surgical patients with especial reference to insulin. L. BAUMAN. *Surgery, Gynecol., Obstetrics* **41**, 272-83(1925).—Prophylactic use of glucose and insulin has given good results with both diabetic and non-diabetic cases requiring surgical treatment and in which acidosis was present. A. T. CAMERON

Diabetic and non-diabetic glucosuria in the surgical patient. W. C. MENNINGER. *Surgery, Gynecol., Obstetrics* **41**, 454-9(1925).—Of 47 cases treated before the use of insulin there were 20 deaths and of 22 cases treated with insulin there was one death. Traumatic glucosuria may be effectively treated, when necessary, with insulin. A. T. CAMERON

Carbolic acid in malaria. J. E. M. BOYD. *J. Roy. Army Med. Corps* **45**, 138-9(1925).—Administration of dil. phenol and tincture of I has given good results in several cases of the crescent stage of malignant tertian malaria in which patients did not respond to quinine. A. T. CAMERON

Gentian violet intravenously in chorea and encephalitis. J. W. VISHNER. *J. Nerv. Mental Dis.* **62**, 376-80(1925).—Three cases of encephalitis following typhoid fever and one case of chorea with endocarditis showed prompt recovery following intravenous injection of gentian violet. A. T. CAMERON

The borocaines: A new class of local anesthetics. A. J. COPELAND AND H. E. F. NOTTON. *Brit. Med. J.* **1925**, II, 547-51(1925).—The action of a local anesthetic depends on the sp. selective affinity of its base for nerve fibrils. The action of different salts of such a base varies greatly according to the acid with which they are combined, and is optimal if combined with a weak acid so that the p_H of the soln. is high. In this case absorption into the general circulation is slow (low toxicity), and the local effect is correspondingly greater (sp. anesthetic effect high). The borocaines—borates of ethocaine and similar compds.—fulfil this condition. They are less toxic than the corresponding hydrochlorides, but have often more than 10 times the anesthetic action. A. T. CAMERON

Introduction of germanium in therapy. J. MESSNER. *Pharm. Zentralhalle* **66**, 632-3(1925).—An address. W. O. F.

The concentration of quinine in the circulating blood. H. W. ACTON AND R. N. CHOPRA. *Indian J. Med. Research* **13**, 197-204(1925).—The absorption of quinine increases when an excess of OH ions is present and diminishes with an excess of H ions. The concn. of quinine is greater in the mesenteric blood than in the systemic blood. FRANCES KRASNOW

The effect of formalin on snake venom. II. Diminution of toxicity of daboia venom. C. DE C. MARTIN. *Indian J. Med. Research* **13**, 109-10(1925); cf. C. A. **19**, 2708.—Formalin diminishes the toxicity of daboia venom but not to the same extent as cobra venom. FRANCES KRASNOW

Note on the anesthesia produced by intra-arterial injection of apothesine. J. P. ARLAND. *Indian J. Med. Research* **13**, 95-6(1925).—"The anesthesia was perfect and profound." FRANCES KRASNOW

The distribution of injected sulfates in tissues.* W. DENIS AND STELLA LECHE. *J. Biol. Chem.* **65**, 565-70(1925).—"In a series of expts. in which hypertonic solns. of Na_2SO_4 were administered to dogs by intravenous injections it was found by analysis of the blood, muscles and viscera that there is little absorption of the SO_4 ion by the tissues, although even 2 hrs. after injection the sulfate content of the blood may still be 10 times its initial value." A. P. LOTHROP

Synergism of magnesium sulfate and morphine and magnesium sulfate and ether. J. T. GWATHMEY. *J. Am. Med. Assoc.* **85**, 1482-5(1925).—Synergism between MgSO_4 and morphine occurs in man. With lab. animals this synergism is life-saving when Et_2O vapor is used as the anesthetic. When properly applied the dose of Et_2O to produce and maintain satisfactory anesthesia is reduced by one-half or more. L. W. R.

"Fitochinina," a substance that activates carbohydrate metabolism. CONDORELLI. *Riforma Medica* **41**, 745(1925); *J. Am. Med. Assoc.* **85**, 1338.—This substance, which was obtained by alc. extn. of leaves of grains, rapidly reduces the sugar content of the

blood, and usually of the urine of pancreatectomized dogs, and of diabetic patients. The tolerance for carbohydrates is augmented for some time after the administration of the substance. It is not pptd. by picric acid, thus differing from insulin and glyco-phytin. "Fitochinina" does not show any appreciable action in the normal person; in this respect it resembles the vitamins. It appears to be harmless and is not pptd. by the usual reagents that act on albumin. L. W. RIGGS

Distribution and excretion of bismuth with different administration methods. I. BIRÓ. *Magyar Orvosi Archivum* 26, 335-45(1925).—The resorption and distribution of Bi in the animal organism are rather independent of administration methods. The largest part of the Bi is deposited in the kidneys and is excreted with the urine. Considerable Bi will be excreted with the feces. Bi is also deposited in the liver, spleen, bone marrow, brain and spinal cord. L. W. RIGGS

Behavior of blood sugar and liver glycogen under the influence of morphine. M. FRANK AND G. FÖRSTER. *Magyar Orvosi Archivum* 26, 296-300(1925).—The hyperglucemia arising after doses of morphine reaches its max. in 2.5 hrs., then sinks to its normal value. Morphine mobilizes the liver glycogen, the expts. with rabbits showing a gradual lowering of the liver glycogen and corresponding rise in the blood sugar. The glycogen mobilization and the hyperglucemia are between certain limits independent of the quantity of morphine administered. L. W. RIGGS

Local irritation caused by the infusion of digitalis. MASAKAZU NAKAMURA. *Tohoku J. Exptl. Med.* 6, 278-84(1925).—Rabbits were given subcutaneous injections of the drug and the following local irritation was estd. by the degree of severity of the resulting symptoms. Digitalis infusions of 1 to 100, also these dild. 50 times, were thus tested. The local action persisted for 3 days after the injection, but disappeared almost completely when the infusion contg. 0.2% HCl was allowed to stand 6 hrs. at 27°, or was heated before injection. Digitoxin, digitalein, digitalin and digitonin each showed a local action which was hardly influenced by the presence of 0.2% HCl; consequently the local action of the digitalis infusion is not to be referred to these substances. The heart action of the infusion is not affected by the presence of 0.2% HCl. This fact may be utilized in the administration of the infusion by the alimentary canal. L. W. R.

Gas metabolism and minute volume. I. The relation of gas metabolism and minute volume to the internal secretion. TSUTOMU ODARIA. *Tohoku J. Exptl. Med.* 6, 325-63(1925).—Tests were made with rabbits in which the O consumption per min. and the minute vol. (m. v.) were measured. By m. v. is meant the ratio of the O consumption per unit of time (O_2) to the difference between the O in 1 cc. of arterial blood (O_A) and the O in 1 cc. of venous blood (O_V), or $m. v. = O_2 / (O_A - O_V)$. Intravenous injections of adrenaline in doses of 0.015 to 0.03 mg. per kg. increase the O consumption and m. v.; the greatest increase in each factor was noted with a dose of 0.025. Larger doses caused a decrease in both factors. Pituitary ext. had slight or no influence on the O consumption until the dose reached 0.17 cc. or more per kg. when a decrease was observed. At the same time a decrease up to 38% in the m. v. was observed, with a still greater decrease following doses above 0.17 cc. Feeding thyroidin (Parke-Davis) to rabbits caused the O consumption to increase from 45 to 144% and the m. v. to increase 70 to 221%. After thyroidectomy in rabbits the decrease in O consumption ranged from 10 to 52% and the m. v. decrease ranged from 18 to 69%. Rabbits fed thyroidin 4 to 8 days, or long enough to produce a state of hyperthyroidism, were given an intravenous injection of adrenaline in doses ranging from 0.015 to 0.5 mg. per kg. one to 4 days after the last feeding of thyroidin. Doses of 0.015 and 0.025 mg. produced no change in the O consumption, but 61 and 15% increase, resp., in the m. v. Doses of adrenaline above 0.03 mg. caused a decrease up to 46 and 53%, resp., in O consumption and m. v. Thyroidectomized rabbits were given injections of adrenaline 25 to 42 days after the operation. There was a small increase of O consumption after doses of 0.03 to 0.15 mg., but larger doses caused a decrease. The m. v. was increased by doses up to 0.25 mg. It was decreased by a dose of 0.5 mg. Pituitrin injected intravenously caused a decrease of O consumption and m. v. in both hyperthyroidism and athyroidism. Normal rabbits given 1.5 units of insulin per kg. showed a decrease in O consumption and m. v., but doses of 0.2 unit per kg. showed an approx. parallel increase in each of these figures. L. W. RIGGS

The pharmacological action of amines on organs containing involuntary muscles. MASAKAZU NAKAMURA. *Tohoku J. Exptl. Med.* 6, 367-88(1925).—The amines used in this study were of known purity or were purified when necessary. Just before use the amines were dissolved in Ringer soln. and made neutral. The tissues and organs used were isolated from frogs, rabbits or cats. The action of amines on the surviving tissues and organs consisting of the involuntary muscles differs in character with the variety

of the compds. though they may in some cases cause the same effect. Each of the 11 aliphatic amines examd. has a stimulating action on the contractile elements, the activity of which increases from methyl- to hexylamine, the iso-forms being less active than the corresponding normal ones. Of these compds. only isoamylamine possesses a sympathetic action in addn. to a muscular action. The others are without action; among these is included ethanolmethylamine, which may be regarded as the side chain of the adrenaline mol. Of 8 aromatic amines studied, phenylamine paralyzes the muscular substances, aminoacetophenone and *p*-aminophenol, like many aliphatic amines, stimulate the same elements, and methylaminoacetocatechol stimulates the sympathetic mechanism, just as does adrenaline. The other members such as phenylmethylamine, phenylethylamine, *p*-hydroxyphenylethylamine and aminoacetocatechol have 2 defined actions, the muscular and the sympathetic, which interfere with each other so that the motor effect is more powerful than the inhibitory effect. L. W. RIGGS

Adrenaline hyperglucemia. III. Reducing substances in adrenaline hyperglucemia. TOSHIO OIHARA. *Tohoku J. Exptl. Med.* 6, 191-211 (1925); cf. C. A. 19, 3120.—Expts with rabbits showed that carbohydrates other than dextrose are contained in the blood. The precise nature of these substances has not been detd. As the difference of the results obtained by Bang's method and Epstein's method is more pronounced in adrenaline hyperglucemia, especially in well fed animals, and is scarcely found in alimentary hyperglucemia, this difference may be inferred to result from some carbohydrate driven into the systemic circulation by adrenaline. The difference was greatest in blood of the inferior vena cava. In hyperglucemia caused by either adrenaline or sugar puncture the glycogen content of the inferior vena cava increases. At least a part of liver glycogen goes into the circulation as such and gradually is converted to glucose. IV. Antagonism between the pancreas hormone and the adrenaline. *Ibid* 213-46.—The pancreatic ext. suppresses the adrenaline hyperglucemia when the dose of the latter is not too large. This effect of the pancreatic ext. is seen also in normal animals and in hyperglucemias caused by other means. The pancreatic ext. acts more powerfully after subcutaneous injection than in the intravenous application; it has no influence upon the normal blood pressure and cannot lower the pressure raised previously with adrenaline. The artificial perfusion of the ext. through the peripheral blood vessels by the Laewen-Trendelenburg's method causes no change in the rate of the outflow of Ringer's soln. The ext. produces no change in the enucleated frog's eye-pupil both in normal state and in adrenaline mydriasis. It has no effect on the pupils of dogs either normal or depancreatized. The rectal temp. scarcely changes until collapse occurs. The rise of blood sugar caused by puncture is powerfully reduced by the subcutaneous injection of the ext. The pancreatic ext. in acid reaction inhibits the movements of the intestine but this phenomenon is probably to be attributed to acid reaction of the ext. The substance itself which causes the fall of blood pressure has no effect upon the intestinal movements. Pituitrin has no obvious inhibiting influence upon the fall of blood sugar caused by the pancreatic ext. The ext. has no effect upon the contraction of the surviving uterus-strip of the cat either in normal condition or in condition when contracted with adrenaline. L. W. RIGGS

Physiological action of furan. ELIZABETH M. KOCH AND M. H. CAHAN. *J. Pharmacol.* 26, 281-5 (1925).—While furan has some anesthetic and analgesic properties, its toxicity is so great as to eliminate it from consideration for practical use. It seems to be a general protoplasm poison, completely inhibiting the growth of yeast. When given by inhalation it causes convulsions, followed by paralysis of the respiratory center and asphyxia. When administered in small doses by mouth it has a corrosive, solvent effect on the mucosa, causing a copious watery secretion. There is an increased permeability of the blood vessels, frequently producing extensive hemorrhages. Injection of 1.5 cc. into a 10 kg. dog caused immediate death with symptoms and post mortem changes similar to those seen in acute HCN poisoning. C. J. WEST

Inactivation of atropine sulfate by rabbit serum. JEAN LA BARRE. *J. Pharmacol.* 26, 259-79 (1925).—The inactivation of atropine by rabbit serum, observed previously by various authors, was confirmed by both chem. and physiol. methods, the 1st expts showing that rabbit serum at 38° could inactivate about 30% of the alkaloid added to it in 2 hrs. The figures obtained did not show any great individual variations in inactivating power of the sera of different rabbits. Ultrafiltration was employed to ext. the atropine without having recourse to heating or to the addn. of any substance that might modify it. 60-65% of the alkaloid was found in the ultrafiltrate of the serum-atropine mixt. which had been left for 2 hrs. at 38° and in the residue 6%. Prolongation of the time of contact of the atropine and serum up to 6 hrs. and increase in temp. from 18° to 42° favor the inactivation of the atropine by the rabbit serum. Thus, the

inactivation can be attributed only in the slightest degree to adsorption, the chem. destruction of the alkaloid being the most important factor involved. An amt. of tropine was recovered sufficient to account for the atropine lost through exposure to the serum.

I—ZOÖLOGY

R. A. GORTNER

Poison production by animals from the zoölogical-physiological viewpoint. J. STROHL. *Biol. Zentr.* 45, 513-36(1925).—A discussion. FRANCES KRASNOW

The biological factors involved in the destruction of river-fisheries by pollution due to lead mining. K. E. CARPENTER. *J. Appl. Biol.* 12, 1-13(1925).—A continuation of studies previously reported (cf. *C. A.* 18, 3233). The present article includes expts. on the toxicity of Pb compds. to various fresh-water fishes and analyses of river waters which have been polluted due to lead mining. C. H. R.

The control of biaxial development in the reconstitution of pieces of *Planaria*. C. P. RUSTIA. *J. Exptl. Zool.* 42, 111-42(1925).—Increase of biaxial head frequency has been obtained with compds. possessing very different phys. and chem. properties and is regarded as detd. by quant. changes in the physiol. condition of the pieces. The exptl. data are interpreted in terms of physiol. gradients; they offer no support to conceptions of polarity in terms of stratification or flow of substances or of mol. structure and orientation. Other physiol. data are given. C. H. R.

Regeneration after dissociation (an experimental study on sponges). I. Behavior of dissociated cells of *Microciona prolifera* under normal and altered conditions. P. S. GALTISOFF. *J. Exptl. Zool.* 42, 183-220(1925).—A suspension of cells of *Microciona* forms aggregates due to contact during ameboid movement. Coalescence is the result of accident, and increases with the temp. between 9° and 19°, following van't Hoff's rule. In hypertonic sea water, movement and coalescence of the cells stop when the salinity reaches 55.8%; at 43.4% coalescence is incomplete. In hypotonic sea water the min. concn. for coalescence is between 9.3 and 12.4%. Ameboid movement ceases and aggregates do not form in isotonic NaCl and KCl solns. The inhibitory action of the Na and K ions may be counteracted by the addn. of Ca and Mg ions. Ameboid movement and coalescence take place in isotonic MgCl₂ soln., but isotonic CaCl₂ soln. is toxic. Cations may be placed in the following descending order of effectiveness on ameboid movement and coalescence: Ca>NH₄>Li>K>Mg>Na. Low concns. of HCl cause a loss of motility; low concns. of NaOH increase the adhesiveness of the cells. In mixts. of cells of *M. prolifera* and *Cliona sulphurea* in normal sea water coalescence occurs only between the cells of a species. Foreign cells mutually inhibit the movement of each other. In alk. sea water *Cliona* cells surround *Microciona* aggregates. CHAS. H. RICHARDSON

The combined toxic action of light and eosin. J. R. PEREIRA. *J. Exptl. Zool.* 42, 257-62(1925).—Neither light nor eosin is toxic to the eggs, sperm or larvae of *Arbacia* for the exposures used. The observed toxicity depends upon the concn. of eosin and length of exposure. Death is due to the transformation of eosin into a secondary toxic product by the action of the light. Eggs and sperm are much more sensitive to the action of eosin and light than the larvae. The injurious influence of light may last after the cells have been removed from sun light. The cells are not stained till death occurs. The toxic action appears to take place at the surface of the cells. C. H. R.

Physical-chemical and chemical investigations on larval and pupal blood (*Pieris brassicae*, *Vanessa urticae*). L. BRECHER. *Z. wiss. Biol., Abt. C* 2, 691-713(1925).—The blood of larvae and pupae of *Pieris* has a p_H value of 6.50-6.77, av. 6.6, as detd. electrometrically with the U-electrode of Michaelis and the microelectrode of Winterstein. Color changes in the pupae under the influence of various light waves cannot be attributed to changes in the reaction of the blood since its H-ion concn. is very const. under differing life conditions. The sp. cond. at 20° is 0.005 av., the same as that of a 0.05 M NaCl soln. The concn. of Cl in the blood is M/35. Unlike vertebrate blood, the blood of these larvae and pupae contains an insignificant quantity of CO₂, approx. 0.001 M, but relatively large quantities of PO₄, about M/45. Its buffer value is due to the latter, but is not so good as that of vertebrate blood. CHAS. H. RICHARDSON

The embryonal metabolism of Teleostei. The amino acids derived from the degradation of the capsule and their relation to the embryo. E. REMOTTI. *Atti Acad. Lincei* [6], 2, 68-74(1925).—These expts. constitute part of an investigation of the biology of teleost eggs. The perivitelline liquid of these eggs was studied to det. the nature of the products of hydrolysis of the capsule and these were detd. by Abderhalden's

ninhydrin reaction. When the liquid obtained by breaking the capsule was tested the presence of amino groups was proved. The reaction was also positive when the liquid was first dialyzed. When the capsule itself was used as a dialyzing membrane the dialyzate failed to show the presence of amino groups. This is another case of strong physiological retention such as has been previously observed in marine animals.

Debatable questions in food chemistry. A. BREYTHIEN. *Z. Nahr. Genussm.* **50**, 42-53(1925).—An address. WILLIAM J. HUSA

The meaning of limiting figures in food chemistry. A. BÖMER. *Z. Nahr. Genussm.* **50**, 75-87(1925).—A discussion of (1) physical and chemical, (2) physiological and (3) legal standards for foods and beverages. WILLIAM J. HUSA

Report on (the examination of) canned foods. A. L. SULLIVAN. *J. Assoc. Official Agr. Chem.* **8**, 641-6(1925).—Collaborative work on the examn. of canned stringless beans showed that all collaborators were able to pick out "flat sours," and that sour beans were found to have a relatively high acidity, large quantities of rod-shaped bacteria, and little or no vacuum in the cans. A. PAPINEAU-COUTURE

Further experiences with hydrocyanic acid fumigation. P. BUTTENBERG, W. DECKERT, AND G. GARTZ. *Z. Nahr. Genussm.* **50**, 92-103(1925); cf *C. A.* **18**, 3657.—Analytical data are given on the HCN content of various foods stored in ships and warehouses during fumigation with HCN. WILLIAM J. HUSA

Milk supply from the standpoint of science, economics and administration. A. JUCKENACK. *Z. Nahr. Genussm.* **50**, 21-37(1925).—An address. W. J. HUSA

Contribution to the study of poisonous milks and their products. FELIX DAELS. *J. pharm. Belg.* **7**, 737-9(1925).—D. has isolated from a sample of milk and from a sample of cheese, which produced death in one case and severe symptoms of poisoning in another, a base which possesses the general properties of hydrocollidine and collidine. It is probably an isomer or a polymer of one of these. A sufficient quantity of the material was not obtained to make an elementary analysis. 0.01 g. administered by mouth to a dog weighing 5 kg. produced vomiting immediately, followed by convulsions. There was copious salivation, accelerated respiration and diarrhea. The animal recovered slowly. The same dose administered subcutaneously produced death in 3 hrs. A. G. DUMÉZ

A review of the chemical and physical methods for testing milk and their value in judging adulterated milk. A. GRONOVER. *Z. Nahr. Genussm.* **50**, 111-9(1925). The f. p. depression of milk shows much less variation for individual cows, both healthy and diseased, than sp. cond., refraction, etc., and is, therefore, of particular value in detecting diln. of milk. WILLIAM J. HUSA

A new method for the detection of neutralized milk. J. TILLMANS AND WERNER LUCKENBACH. *Z. Nahr. Genussm.* **50**, 103-11(1925).—In 50 cc. of milk det. the degree of acidity (Soxhlet and Henkel). Add 38 cc. of a colloidal iron soln. (Liquor ferri oxydati dialysat. D. A. B. 5), mix well, let stand 15 min. Pour on to a folded filter and let as much serum as possible run through. Place 20 cc. of the serum in a 50-cc. cylinder and neutralize to phenolphthalein (p_H 8.1) with 0.1 N NaOH. Titrate with 0.1 N HCl to p_H 3.2, the indicator being 0.3 cc. of a 0.01 soln. of dimethylaminoazo benzene in 90% alc. The end point is judged by comparison with a similar cylinder contg. the indicator with 20 cc. of a buffer soln. of p_H 3.2. (The buffer soln. is made by dissolving 21.008 g. of citric acid in 200 cc. of N NaOH, dilg. to 1 l., then mixing 43 cc. of this soln. with 57 cc. 0.1 N HCl.) The titration is calcd. for 100 cc. of milk and the corresponding acidity is read off from a curve or table showing the relation between the degree of acidity and the no. of cc. of 0.1 N HCl required to titrate 100 cc. of milk from p_H 8.4 to p_H 3.2. If the degree of acidity actually found is less than the value indicated by the table, the milk in question has been neutralized from the value indicated in the table to the value detd. Differences of 1 to 2 degrees (Soxhlet and Henkel) arouse suspicion, while larger differences indicate definitely that the milk has been neutralized. W. J. H.

The estimation of citric acid in milk. B. BLEYER AND J. SCHWAIBOLD. *Milch-wirtschaft. Forsch.* **2**, 260-311.—B. varies the method of Kunz (*C. A.* **9**, 687) by using KBr and H_2SO_4 instead of Br water in oxidizing citric acid to pentabromoacetone. He centrifuges in a graduated tube instead of using a Gooch crucible. This method

checks the theoretical results of Soldner (Handbuch der Milchkunde, Weisbaden, 1909), more closely than does the method of Kunz.

GEORGE R. GRENBANK

Determination of cane sugar in condensed milk. K. SCHERINGA. *Pharm. Weekblad* 62, 1034-5(1925).—A formula is given for calcg. % of sucrose in the presence of lactose in condensed milk, from detns. of optical rotation and reducing power.

A. W. DOX

Variations in the percentage of butter fat in milk. V. Summary of the investigations. W. N. PATON. *New Zealand J. Agr.* 31, 110-4(1925); cf. *C. A.* 19, 2379, 2713.

K. D. JACOB

The bacterial content of ice cream. A report of experiments in bacterial control in six commercial plants. N. E. OLSON AND A. C. FAY. *J. Dairy Sci.* 8, 415-44(1925); cf. *C. A.* 18, 3651.—The finished ice cream from the supervised batches averaged $1/10$ as high in bacterial counts as that from the regular manuf. Important sources of bacterial contamination were found to be the following: cream and milk (most important of all); careless washing of coolers; failure to take apart conveying pipes, pumps and homogenizers in cleaning; use of pasteurizing equipment in successive batches without washing; leaving mix for aging without previous proper cooling; failure to cool immediately after homogenizing. Other recommendations are: use alk. washing powders, hypochlorite solus. and live steam in cleaning all equipment; pasteurize at 145° F. for 30 min. and homogenize at that temp. If ice cream contains more than 100,000 bacteria per g. (plate method), carelessness in the manuf. is indicated. FRANK S. RICE

Gelatin as a source of bacteria in ice cream. J. M. BRANNON AND P. H. TRACY. *J. Dairy Sci.* 8, 115(1925).—Addn. of gelatin results in very slight increase in number of bacteria.

JACK J. HINMAN, JR.

The salt content of butter and its influence on quality. E. HAGLUND AND E. WALLER. *Kgl. Landtbr. Akad. Handl. och Tidskr.* 64, 483-98(1925).—Samples of butter from 368 creameries were analyzed. The av. salt content was 1.15% and varied from less than 0.5% to over 2.25. Nearly half had a salt content between 0.75% and 1.25. Evenness in salting was as common with creameries using large amounts of salt as with those using small amounts. The quality rating of butter was higher with the creameries using the smaller amounts of salt.

C. O. SWANSON

The colorimetric determination of the acidity of cheese and whey. B. J. HOLWERDA. *Verslag. Landw. Onderzoek. Rijkslandbouwraproefsta.* No. 30, 220-3(1925).—The colorimetric detn. of the H-ion concn. of whey may be carried out by using suitable indicators. Methyl red and neutral red were found to be satisfactory indicators, while bromothymol blue, bromocresol purple and *p*-nitrophenol gave incorrect results. Well-washed neutral infusorial earth may be used for clarifying cloudy whey without affecting the H-ion concn. The H ion of cheese can be detd. by shaking 10 g. of cheese with 30 cc. of lactic acid-NaOH mixts. of different H-ion concns. The supernatant liquid is decanted after not less than 3 min., indicator (0.2 cc. of a 0.2% soln.) is added to 15 cc. aliquots and the resulting colors are compared with that of the same concn. of indicator in the original mixts. The mixt giving the same H-ion concn. before and after contact with the cheese is taken to indicate the H-ion concn. of the cheese. Methyl red was found to be a satisfactory indicator—giving results comparable to the electrometric method.

R. M. BARNETTE

Determination of coconut oil in edible fats by means of the ethyl ester number. JAN LUKAS. *Chem. Listy* 19, 307-12(1925); cf. *C. A.* 6, 690.—The Et ester number is more suitable for analysis of edible fats than the Polensky number, which yields low values on artificial mixts. of known compn.

F. C. KRACEK

A proposal for expansion or modification of rules for valuation of cacao and cacao products. F. HARTEL. *Z. Nahr. Genussm.* 50, 122-35(1925).—A discussion of proposed specifications for cacao products.

WILLIAM J. HUSA

The bacterial flora in preserved eggs. HANS POPP. *Z. Nahr. Genussm.* 50, 139-11(1925).—The bacteria found in dried egg powders and preserved yolks were such as normally occur in many raw materials and would generally be rendered harmless by the heat used in prepn. of foods, except in mayonnaise, etc.

W. J. H.

Report on the determinations of the acidity of the fat and of the acid-insoluble phosphoric acid in (dried and liquid) eggs. H. I. MACOMBER. *J. Assoc. Official Agr. Chem.* 8, 604-10(1925).—The neutral extn. method for lipoids (Hertwig, *C. A.* 17, 3386)

measures more accurately the quantity of fat present than the direct extn. method. *S. Dept. Agr. Bull.* 846, p. 90; but the final soln. is too highly colored for satisfactory acidimetric titration. To det. acidity of the fat, dry the sample to const. wt. 55° under a vacuum of not less than 25 in., ext. with anhyd. Et_2O in a Knorr app. in a Johnson extractor, evap. the Et_2O , weigh the fat, dissolve in 50 cc. of neutral

C_6H_6 (prepd. by refluxing for 6 hrs. with 0.1 vol. of N EtONa, distg., and finally washing 3-4 times with water if necessary), and titrate with 0.05 N EtONa (prepd. by dissolving about 1 cc. of metallic Na in 800 cc. abs. EtOH, titrating with 0.1 N HCl, and dilg. to proper strength with abs. EtOH) in presence of phenolphthalein till the yellow of the H_2O ext. turns orange. Collaborative results were satisfactory for dried eggs, but those for liquid eggs differed very considerably in some instances. Detn. of acid-sol. P_2O_5 by the method described by Pine (*C. A.* 18, 3235) was simplified (1) by reducing the time of extn. by placing in a shaking machine for 30 min., (2) by sepn. of the insol egg material from the ext. by centrifuging and decanting instead of filtering, and (3) by pptg. P_2O_5 as $MgNH_4PO_4$ directly in the H_2SO_4 soln. without preliminary phosphomolybdate pptn. Collaborative results by the modified method were not considered sufficiently satisfactory; this is attributed to insufficient mixing of the samples (especially the yolks) with the HCl soln. before addn. of the picric acid. (Cf. following abstracts)

A. PAPINEAU-COUTURE

Report on methods of analysis of liquid and frozen egg products. M. L. HITCHCOCK. *J. Assoc. Official Agr. Chem.* 8, 610-4(1925); cf. preceding and following abstracts.—Collaborative results on the detn. of H_2O (drying to const. wt. at 98° at a pressure of not over 5 in. abs.), fat by acid hydrolysis (Hertwig, *C. A.* 17, 2621), lipoids and lipid P_2O_5 (Hertwig, *C. A.* 17, 3386), H_2O -sol. protein-N precipitable by 40% EtOH (Hertwig, *C. A.* 17, 3549-50), and total N showed that the methods are quite accurate and that different analysts are able to secure concordant results. The various methods are described in detail. L. H. Bailey reports that drying 1 hr. at 130° at atm. pressure gives results practically identical with those obtained in 5 hrs. at 98° and 5 in. abs.

A. PAPINEAU-COUTURE

Report on methods for the analysis of (powdered) dried (whole) eggs. J. C. PALMER. *J. Assoc. Official Agr. Chem.* 8, 615-21(1925); cf. preceding and following abstracts.—Comparison of results obtained by drying to const. wt. at 98° and 6 in. pressure (abs.), 98° and 2.5 in. and 55° and 2.5 in. showed that max. H_2O content is obtained by heating at 98° for 5 hrs. at a pressure not over 2.5 in. abs. In the detn. of fat by acid hydrolysis (Hertwig, *C. A.* 17, 2621) max. fat content was obtained by hydrolyzing at $75-80^\circ$ instead of 70° . In the detn. of lipoids and lipid P_2O_5 most of the H_2O -sol. material must be removed before proceeding with the neutral extn., and the extd. sample should be pulverized with $CaCO_3$ (results about 0.5% lower without $CaCO_3$ than with it). Max. results were obtained with a 1-2 g. sample. Best results for total N were obtained by the Kjeldahl-Gunning-Arnold method with a 2-hr. digestion period after clearing. In the detn. of H_2O -sol. protein-N precipitable by 40% EtOH (Hertwig, *C. A.* 17, 3549-50) trouble was encountered in filtering the pptd. albumin, and in obtaining concordant results for the H_2O -sol. N content. The first was overcome by detg. the pptd. albumin by difference between N contents of the albumin soln. before and after pptn. with 40% alc., and the second by extg. the albumin with 1.2% NaCl soln. instead of H_2O . The various methods are described in detail.

A. PAPINEAU-COUTURE

Report on (the determination of) zinc in eggs. W. E. KIRBY. *J. Assoc. Official Agr. Chem.* 8, 621(1925); cf. preceding and following abstracts.—Gravimetric detn. of Zn as $HgZn(CNS)_4$ (Lundell and Bee, *C. A.* 8, 3404) gives satisfactory results on pure solns. of Zn. Efforts are being made to adapt it to the ash obtained from dried eggs or to the acid digestion product of dried eggs.

A. PAPINEAU-COUTURE

Report on (methods of analysis of) eggs and egg products. RAYMOND HERTWIG. *J. Assoc. Official Agr. Chem.* 8, 594-604(1925); cf. preceding abstracts and *C. A.* 19, 547.—A discussion of the results reported, with recommendations for adoption of the methods as tentative and for continuation of the work. The technics of the methods recommended are described in detail.

A. PAPINEAU-COUTURE

Determination of egg-yolk oil. HANS POPP. *Z. Nahr. Genussm.* 50, 135-8 (1925).—The results of detns. of fat in dried or preserved egg yolk vary with different solvents, depending on the soly. of lecithin. P. applies the method of Grossfeld (*C. A.* 19, 3548), in which the diglyceride formed by splitting off the phosphoric acid choline group from lecithin is included in the total fat. The free fatty acids in egg powder are detd. by extg. 5 g. of egg powder with neutral ether-alc. mixt. for 1 hr. at room temp., filtering, washing and titrating the filtrate with 0.1 N alkali. W. J. H.

Sugar and saccharin. A. TRÄGEL. *Deut. Zuckerind.* 50, 1175-6(1925).—Saccharin was boiled with dil. solns. of oxalic, acetic, tartaric and malic acids. The taste of the fresh solns. was satisfactory; after 3 hrs. boiling the taste was somewhat unpleasant; and after 5 hrs. boiling the sweet taste had disappeared, the taste was very unpleasant, and there was a very bitter aftertaste. Similar results were obtained

in cooking apples with saccharin. Ten % of the sugar needed ~~could be replaced with~~ saccharin, but if more than that amt. of saccharin was used, the ~~taste was unpleasant~~ after boiling 30 min.

Report of Committee on Baking Tests (American Association of Cereal Chemists). S. A. FITZ. *Cereal Chem.* 2, 232-5(1925).—The following recommendations for a tentative standard formula for baking tests for hard wheat flour were made. Flour 325 g., sugar 10 g., salt (high-grade) 5 g., yeast (compressed) 10 g., pure lard 7 g., distd. water, q. s. It is recommended that 1 lb. of yeast be obtained as fresh as possible, directly from the manufacturer, and that all outside surfaces be trimmed off and discarded. No definite recommendations are given for scoring or for handling dough. R. B.

Science in experimental baking. C. A. KRESS. *Cereal Chem.* 2, 228-32(1925).—Attention is called to the necessity of scientific methods for baking and the important tests are discussed. RUTH BUCHANAN

The gluten quality of flour and its iso-electric point. E. L. TAGUE. *Cereal Chem.* 2, 202-8(1925).—The point of min. transference or neutral point (corresponding to the isoelectric point in a pure substance) is proposed as a logical basis for the study and correlation of the different factors influencing gluten quality of flours. A method is given by which this point as well as the acidic and basic strength of a given flour can be accurately detd. Curves given show the behavior of different grades of flour as well as the different constituents of the given flour within the zone (p_H 4.5 to 7) important in gluten formation. No relation is apparent between the H-ion concn. of a flour and the point of minimum transference. RUTH BUCHANAN

Report on meats and meat products. (Determination of nitrites in cured meats.) R. H. KERR. *J. Assoc. Official Agr. Chem.* 8, 696-7(1925).—Adoption of the following method is recommended: to 5 g. of comminuted sample in a 50-cc. beaker add 40 cc. of HNO_3 -free water at 80°, mix thoroughly, wash into a 500-cc. volumetric flask to a vol. of approx. 300 cc., heat on a steam bath for 2 hrs. with occasional shaking, add 5 cc. satd. $HgCl_2$ soln., mix, cool to room temp., dil. to 500 cc. mix, filter, and det. HNO_2 -N in a suitable aliquot by the official method for nitrites in water. A. P.-C.

Report on methods of analysis for meats and meat products. (Determination of reducing sugars.) W. C. POWICK. *J. Assoc. Official Agr. Chem.* 8, 697-8(1925).—In using phosphotungstic acid to remove non-coagulable proteins, creatinine, etc., in the detn. of reducing sugars, trouble was experienced in some cases in the final reduction. Attempts to locate the source of the difficulty were unsuccessful, but indicated that the trouble is not due to incomplete removal of creatinine, to the presence of 1:18 phosphotungstic acid in the specimens of 1:24 phosphotungstic acid employed, nor to variations in the exptl. conditions, length of standing, etc., obtained at different stages of the investigation. Fermentation methods would be preferable to reduction methods for this detn. owing to the possible presence of reducing non-sugars. A. P.-C.

Report on (the analysis of) flavors and non-alcoholic beverages. J. W. SALE. *J. Assoc. Official Agr. Chem.* 8, 686-96(1925).—Comparison of the Folin and Denis (*C. A.* 7, 1769) and official A. O. A. C. methods for *vanillin detn.* showed excellent agreement between the 2. The Wichmann method for detn. of *Pb no. in vanilla exts.* (*C. A.* 15, 2518) and the detn. of the *Pb* as chromate instead of sulfate (cf. Clemens, *C. A.* 18, 3235) are recommended for adoption as official. Comparative results for the *detn. of oil in lemon, orange, peppermint, anise and nutmeg exts.* of known compn. by the official polarization method, official pptn. method, Peniman-Randall method (*C. A.* 8, 3837), and a modification of the latter using 1 cc. of HCl (1+1) and water instead of the acidulated $CaCl_2$ soln. were not sufficiently conclusive to warrant adoption of the new methods. Variations in individual results were greater by the new methods than by the official ones. In detg. oil by pptn., the same correction (0.4%) for soly. of the non-terpene constituents should be made with orange exts. as with lemon exts. Results obtained by Horvet and West's method (*C. A.* 3, 1189) for the *caln. of alc. in lemons, orange, peppermint, anise and nutmeg exts.* of known compn. showed the method is accurate, and it is recommended for adoption as official. A. PAPINEAU-COUTURE

Composition of sugar beet pulp and tops and of silage therefrom. S. F. SHERWOOD. U. S. Dept. Agri., *Circ.* 319, 1-11(1924).—Analyses are given of a number of samples of beet pulp, beet tops and silage prepd. from beet tops grown in a number of Western states. The ash content on a water-free basis of clean beet tops was found to vary from 12 to 15%, but when the dirt was not removed one-half the samples had a crude ash content of 25% with a max. of 29%. The crude ash content on a water-free basis of beet top silage varied from 20.8 to 58.5%. W. H. ROSS

Significance of occurrence of copper, manganese and zinc in forage crops and foods. J. S. MCHARGUE, *J. Am. Soc. Agron.* 17, 368-72(1925).—Fertile soils contain small

amts. of Cu, Mn and Zn and plants absorb small amts. which are stored in leaves and in pericarp and germ of seeds. When wheat and corn are highly milled they are deprived of the greater part of Cu, Fe, Mn and Zn which appear to be important in animal nutrition. Some depleted soils require small amts of Cu, Mn and Zn. J. J. H., Jr.

Some effects of seasonal conditions upon the chemical composition of American grape juices (CALDWELL) 11D. Nitrogenous fertilizer or stock feed (U. S. pat. 1,561,667) 15.

Chlorine gas control for flour bleaching. W. STEIN. U. S. 1,562,380, Nov. 17. Cl is passed through a body of liquid (e. g., H₂O) in a graduated transparent tubular vessel which serves as a sight gage of the Cl supply and is then passed through a transparent moisture-sepp. vessel.

Nitrogen trichloride in bleaching flour. WALLACE & TIERMAN CO. AND J. C. BAKER. Brit. 232,607, April 21, 1924. Cl and an NH₄ compd. are brought together as described in Brit. 159,166 (C. A. 15, 2134) in soln. and the NCl₃ is removed in a stream of inert gas, after the reaction is complete. Several examples are given.

Apparatus for testing the "bread-making qualities" of flour. L. BAUMANN. Brit. 232,585, April 16, 1924. Flour is made into a dough and the tenacity and extensibility of the dough (in the form of a disk) are tested by pressing it against a round-ended die and noting the pressure required to rupture the disk.

Pasteurizing milk. D. F. WISEMAN. U. S. 1,550,860, Aug. 25. The temp. of the milk is rapidly raised to about 50° by maintaining H₂O or other circulating medium at a temp. to maintain the contact surfaces with the milk at a temp. below 75° and the milk temp. below 63°.

Apparatus for pasteurizing milk in bulk. M. BLOCK. U. S. 1,550,668, Aug. 25. **Cheese.** W. FAHNDRICH. U. S. 1,561,781, Nov. 17. Small pieces of cheese are heated to form a dough-like mass, a Ca salt and milk sugar are added, and the mass, while hot, is inoculated with a pure culture of *Bacillus bulgaricus* or a similar culture and sealed in packages.

"Butter substitutes." MILK OIL CORPORATION AND C. F. NORTH. Brit. 232,916, April 23, 1924. Fatty substances such as beef fat or tallow or a mixt. of these with milk fat or oil are homogenized in melted condition and emulsified with skim milk powder and H₂O. The emulsion is cooled to about 13°, worked into a butter-like mass, flavored and salted.

Conserved fruits. P. NAVARRE. U. S. 1,560,396, Nov. 3. Fruits are bleached in a strong soln. of SO₂ which is maintained at the b. p. and are then subjected to the action of a sugar sirup at const. temp. and pressure throughout the process. The sirup may have a temp. of about 60° and is circulated under pressure continuously in contact with the fruit and through a reconcentrating app.

Concentrating and drying fruit juices. W. H. DICKERSON. U. S. 1,562,309, Nov. 17. Fruit juices are concd. by freezing, so as to preserve the aromatic ethers, and then dried to a powder by spraying the concentrate into a hot gas.

Flavoring extracts, etc. F. FORAY. Brit. 232,552, April 19, 1924. Ether in liquid or vapor form is used to ext. essential principles of plants, vegetables, fruits, flowers, etc., and the resulting exts. may be mixed with sugar, flour, sago, alc., etc.

Stock food. W. P. M. GRELCK. U. S. 1,561,158, Nov. 10. The starchy part of barley or other grain (or the whole grain) is treated with H₂O and heated. Malt grain is then added and the materials are steeped to produce maltose. The latter is converted into lactic acid in sufficient amt. to have a preservative effect on the product and additional grain is then incorporated in the mixt.

Food for animals and poultry. C. E. CHANNER. Brit. 232,667, Jan. 21, 1924. Sour milk is maintained at about 40° to complete souring and effect partial evapn. and cooking. The temp. is then raised to about 93° until the milk dries to a brown granular mass which is crushed. A current of heated air may be used for drying.

Insulating cement or mortar. L. CALDWELL. U. S. 1,556,488, Oct. 6. A cement or mortar adapted for use in heat insulation consists principally of powd. diatomaceous earth and an org. adhesive such as glue, casein, or waste sulfite pitch, together with not more than 7% of NaCl , borax, K_2SO_4 or other salt which serves as a distending agent for the adhesive.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water and water supplies. H. S. HANCOCK, JR. *Pub. Health J. (Can.)* 16, 36-42(1925).—Early history of public water supplies is outlined, and the supply of Fort William, Ont., derived from Loch Lomond, 6 miles from the city, is described.

R. E. THOMPSON

Lucknow water supply. ANON. *Water & Water Eng.* 27, 263(1925).—Purification equipment consists of 3 m. g. d. Patterson rapid sand filters and old (slow sand) filters. Max. daily capacity is about 9 m. g. d.

JACK J. HINMAN, JR.

Phenol tastes in the water supply of Marquette, Michigan. PAUL HANSEN. *Eng. News Rec.* 95, 469(1925).—The presence of pyroligneous acid and crude wood alc. still

wastes in the water supply of Marquette, derived from Marquette Bay, Lake Superior, has given rise to tastes and odors which are intensified by chlorination. On the basis of the Milwaukee expts. it is proposed that troublesome wastes be partially treated at works of origin and then discharged with city sewage into a reaction tank (designed for possible conversion into an activated-sludge plant) with a retention period of approx. 8 hrs. The ratio of waste to sewage is approx. 1:15. R. E. THOMPSON

The distribution of water in Gloucestershire. L. RICHARDSON AND R. C. S. WALTERS. *Surveyor* **67**, 13-4(1925).—Quantity and quality of water available in Gloucestershire are given. R. E. THOMPSON

The water supply of Gloucestershire. L. RICHARDSON. *Water and Water Eng.* **27**, 264-70(1925).—A geological paper. R. E. GREENFIELD

New London, Conn. ANON. *Eng. News Rec.* **95**, 305-6(1925).—The water supply of New London is derived from Lake Konomoe, a 600-m. g. storage supply about 6 miles from the city. Chlorination is the only treatment employed. R. E. THOMPSON

Brookline, Mass. ANON. *Eng. News Rec.* **95**, 259-60(1925).—Water supply (5 m. g. d.) is obtained from driven wells and underground collecting galleries located on banks of Charles River. The purification works consist of 6 tricklers, a sedimentation basin, and 6 slow sand filters. R. E. THOMPSON

Cincinnati water supply and the U. S. P. H. S. standard. CLARENCE BAHLMAN. *J. Am. Water Works Assoc.* **14**, 260-6(1925).—At present with a chlorine dosage of from 1.5 to 2.5 lbs. per million gallons, the Cincinnati supply at the tap will easily conform to the suggested new U. S. P. H. S. standard. D. K. FRENCH

Water supply in Holland. F. A. LIEFRINCK. *Water and Water Eng.* **27**, 356-61(1925).—The oldest public system is that of Amsterdam, constructed in 1853. 108 undertakings supply 325 communities. 4.6 million out of 7 million inhabitants are supplied from public supplies. Peculiarities of ground water in sand dunes close to the sea are discussed. JACK J. HINMAN, JR.

The water supply of the English army during the European war. D. FEDERICO BEIGHEDER. *Memorial de Ingenieros del Ejército*, Jan. 5-32; Feb. 33-61; *Water and Water Eng.* **27**, 165(1925). JACK J. HINMAN, JR.

The purification of water supplies on field service: a retrospect. WM. HORROCKS. *J. Roy. Army Med. Corps* **45**, 167-89(1925).—A historical account of the development of Horrock's and similar tests and of the various methods of chlorination used in the field during the war, and the results obtained with them. A. T. CAMERON

System of sanitary grading of water supplies. E. S. CHASE. *Eng. News Rec.* **95**, 469-70(1925).—A system of scoring sanitary condition of water supplies is described which consists of a scale of values from 0 to 100 divided into 3 parts of 50, 20 and 30 which are assigned to factors for pollution hazards, protective measures and quality condition, respectively. Max. value indicates perfect or nearly perfect conditions. R. E. THOMPSON

Bibliography on the detection of phenols in water supplies. C. F. SCHURCH. *J. Am. Water Works Assoc.* **14**, 348-51(1925). E. H.

Iodine and water supplies. H. W. CLARK. *Eng. News Rec.* **95**, 470(1925).—The av. I content of 80 Massachusetts water supplies examd. was 2.14 parts per billion, individual supplies having content as high as 6.3 parts per billion. These results are being studied in relation to prevalence of goiter. Use of iodized salt is considered the ideal method of overcoming I deficiency, application of I to water being considered more or less wasteful. R. E. THOMPSON

Use of iodides in water supplies to prevent simple goiter. A. F. MELLEN. *Eng. News Rec.* **95**, 352-4(1925).—Adverse criticisms of iodization are reviewed and commented on. The Minneapolis supply, filtered Mississippi River water, contains only approx. 0.8 parts per billion of I, compared with min. content of 5 parts found in waters in non-goitrous regions. M. has recommended that the deficiency be corrected by addn. of 10 parts per billion of NaI, a proposal which has been favorably considered. The cost of such treatment is estd. at 1½¢. per capita per annum. R. E. THOMPSON

The mineral waters of Saint-Gervais-Les Bains le Fayet (Haute-Savoie). D'ARSONVAL, F. BORDAS AND F. TOUPLAIN. *Ann. fals.* **18**, 454-60(1925).—A description of the 2 springs, the surrounding geological formation and the chem. compn. of the water. The more important constituents of the "Gontard-de-Mey" and "Torrent" springs are: Ca 0.317, 0.2408; K 0.1064, 0.1038; Na 1.2703, 0.8186; Li 0.0104, 0.0063; Cl 1.064, 0.730; SO₄ 2.087, 1.456; total solids (at 180°) 5.075, 3.515; cond. 5.9 × 10⁻³, 4.3 × 10⁻³, resp. Protection of underground water. PERCY GRIFFITH. *Water and Water Eng.* 27, 196-8(1925).—A discussion of the above report. JACK J. HINMAN, JR.

Analyses of rainfall from a protected and an exposed gage for sulfur, nitrates and ammonia. E. M. JOHNSON. *J. Am. Soc. Agron.* 17, 589(1925).—This work was undertaken in order to evaluate the influence of bird droppings on the analysis of rain waters collected from gages. Bird droppings from an old loft showed 0.78% S on dry basis of which 0.58% was water-sol. Less S was found in the water from the exposed gage than in protected gage due to biological action of bird droppings. More ammonia was found in the exposed gage. JACK J. HINMAN, JR.

The purification of waste waters from small and medium-sized communities. ALEX GIRARD. *La technique sanitaire* 20, 215-18(1925).—The capacity of septic tanks for isolated houses and small communities should be 400 to 500 l. per capita, allowing a detention period of 20 to 22 hrs. A capacity of 125 to 200 l. is too small. If the larger capacity is used the effluent will generally be colorless, odorless and contain 50-100 p.p.m. NH_3 , all or nearly all of which disappears in 7 days at 30-32°, being transformed into NO_2 and NO_3 . A contact bed is recommended for the effluent from the tank. JACK J. HINMAN, JR.

Report on the water softening and purification works for the year 1924. C. P. HOOVER. *Supplement to the City Bulletin, Columbus, Ohio* 1924, 29.—Hardness of of the water of the Scioto river was reduced from an av. of 299 p.p.m. to 99 p.p.m. by the plant. Lime, soda ash, alum and Cl were the chemicals employed in treatment. A pumpage of 8700 million gallons was treated at a cost for chemicals of \$20.81 per million gal. JACK J. HINMAN, JR.

Preparation and comparative performance of base-exchange water-softening materials. E. B. HIGGINS AND J. P. O'CALLAGHAN. *Chemistry & Industry* 44, 882-5(1925).—Artificial zeolites show larger percentage of replaceable sodium, but less resistance to disintegration, dissolved carbonic acid and impurities than natural minerals. Also in *Water & Water Eng.* 27, 392-4(1925). HOPE HEFFNER

Recent experience with doucil as a water-softening material. T. P. HILDITCH AND H. J. WHEATON. *Chemistry & Industry* 44, 885-7(1925); cf. *C. A.* 18, 1539.—This complex synthetic aluminosilicate is unaffected by free carbonic acid of natural waters and has a loss by disintegration of less than 5% per annum. H. H.

Correlation of sulfite reduction test with other tests in the bacterial examination of water. W. J. WILSON AND E. M. BLAIR. *J. Hyg.* 24, 111-9(1925).—A special medium

is made of glucose agar (3% agar) to each 100 cc. of which is added 1 cc. FeCl_3 8% soln., 0.6 cc. NaOH 10% soln., 20 cc. Na_2SO_3 20% soln. Forty cc. of water is mixed with 100 cc. media and poured into a large Petri dish. A layer of melted sulfite agar is then poured over the hardened mixt to keep out air. Certain bacteria such as *B. typhosus*, and *B. enteriditis* Gaertner give deep black colonies. Most *B. coli* are unable to discolor media. *B. welchii* and some other forms give dark colored colonies. Bacteria responsible for vegetable decay are in general not sulfite reducers. J. J. H. JR.

Purification of waste waters by fish ponds and particularly waste waters from cellulose factories. H. SELTER AND E. W. HILGERS. *Arch. Hyg.* **94**, 264(1924); *Bul. mens. office internat. d'hyg. publ.* **17**, 792-3(1925).—Exptl. results show that the process is feasible if wastes make up $\frac{1}{4}$ or less of the water. JACK J. HINMAN, JR.

Bacteriological purification of drinking water with alkaline hypochlorites and liquid chlorine. D. F. RICART. *Memorial de Ingenieros del Ejercito*, Nov., 1924; *Water and Water Eng.* **27**, 79(1925).—A general and comprehensive paper dealing with permanent and military installations. JACK J. HINMAN, JR.

Use of potassium permanganate in drinking water for poultry. SIVERT ERICKSEN. *J. Am. Vet. Med. Assoc.* **67**, 496(1925).—Added to pink color. Recommended as very effective. JACK J. HINMAN, JR.

Irritant poisons in water from shell holes. WILH. HARTMANN. *Chem.-Ztg.* **49**, 473(1925).—Waters were found to be poisoned from shell gas. It is believed that the Cl and Br split from the acetyl halides and reacted with the organic compds. in the water forming poisons which caused vomiting and intestinal disorders. K. C. B.

Treatment of alkali and other waters for domestic use. G. A. CUMMINGS. *Colorado Agr. Expt. Sta. Rept.*, p. 40(1924); *Expt. Sta. Rec.* **53**, 185(1925); *Pub. Health Eng. Abst.*, Sept. 26, 1925, Water Supplies, p. 57.—Distillation is the only suitable method. JACK J. HINMAN, JR.

The more unusual gases occurring in Imhoff tanks. F. L. CAMPBELL AND WILLEM RUDOLFS. *Eng. News-Rec.* **95**, 552-3(1925).—Fifty analyses of gases from Imhoff tanks at Plainfield, employing both combustion and absorption methods, have failed to reveal presence of H_2 , confirming the results of Imhoff, who attributes absence of H_2 to its combination with CO_2 to form CH_4 . This is considered improbable by C. and R. By expt. it was found that H_2 in contact with sludge disappears, but that this phenomenon does not occur if sludge is first sterilized. Studies are being undertaken to determine whether H_2 disappearance is due to chem. combination, absorption, or to catalytic action of living organisms. Hydrogen sulfide has been detected in one tank which had been cleaned for alterations and put in operation again. The sp. gr. of tank gases calcd. from analyses has been found to be significantly higher than values obtained by direct detn. with Schilling's app., indicating presence of other light gas or gases. R. E. THOMPSON

The Fort Worth Imhoff tank accident. H. L. THACKWELL AND F. A. JONES. *Eng. News-Rec.* **95**, 278(1925).—Discussion of the Fort Worth explosion (cf. following abstracts) which is considered a good illustration of the effect of accumulated scum in Imhoff tanks of the open gas vent type. A method of exhausting and utilizing the gas for heating the sludge, thus promoting digestion, is described briefly. In existing tanks having scum trouble the CO_2 can be removed by injecting NaOH soln. into floating scum, thereby allowing the escape of lighter gases. R. E. THOMPSON

Fort Worth Imhoff tank accident. T. R. CAMP AND C. F. LEWIS. *Eng. News-Rec.* **95**, 482(1925).—Discussion. (Cf. following abstr.) R. E. THOMPSON

Fort Worth Imhoff tank explosion recalls one in South Carolina. MCKEAN MAF FITT. *Eng. News-Rec.* **95**, 278(1925); cf. preceding abstr.—Description of explosion, due to firing of gas accumulation, in small plant operating as a septic tank. R. E. T.

Boiler feed water purification. A. S. BEHRMAN. *Mech. Eng.* **47**, 909-10(1925).—Boiler feed water purification is classed as external and internal treatment. Lime-soda ash pptfr. is the oldest of the external treatments. Temporary hardness is thus removed by sedimentation or filtration and the sulfates and chlorides of Ca and Mg are converted into the Na salts. In the zeolite process the temporary hardness is replaced by an equiv. quantity of soda, increasing the tendency to foam and prime. There seems to be a relation between excess soda and embrittlement. Excess soda ash treatment within the boiler to prevent the formation of CaSO_4 scale is used but cases are known where scale has formed with such treatment. The hot process of soda lime treatment is more effective in removing CaCO_3 than the cold because of the formation of colloidal CaCO_3 in the cold process. Attention is called to the necessity of consideration of local conditions for the best results. BEN H. PETERSON

The "Filtrator" apparatus for the prevention of scaling of boilers. ANON. *Le*

Génie civil 84, 410(1924).—This is not a filter, but an apparatus by means of which steam extracts a mucilaginous material from flaxseed and returns with it to the boiler. The emulsion formed is claimed to coat the particles of the precipitate and prevent formation of adherent scale.

JACK J. HINMAN, JR.

East Durham water for boiler and other purposes. W. G. CAREY. *J. Soc. Chem. Ind.* 44, 286-90T; *Water and Water Eng.* 27, 229-33(1925).—A general paper on the softening of a hard magnesian water by various methods and including discussion of the removal of oil and dissolved gases. The source is wells 140 to 500 feet deep from which 10 m.g.d. is obtained. Sanitary quality is good.

JACK J. HINMAN, JR.

The chemical purification of the boiler feed water of locomotives on the Paris, Lyons-Marseilles system. VIGNAL. *Rev. gen. de chemins de fer*, May, 1925; *Le Génie civil* 87, 67-8(1925).—The lime-soda process is used.

JACK J. HINMAN, JR.

What is the present trend in water works design and operation? WELLINGTON DONALDSON. *Cont. Rec.* 39, 854-7(1925).—Review and discussion of trend of water works practice with regard to aeration, sedimentation, coagulation, chem. application, filter sand bed, filter auxiliaries and chlorination.

R. E. THOMPSON

A modern water-softening and filtration plant. ANON. *Fire and Water Eng.* 78, 399(1925); *Pub. Health Eng. Abst.*, Sept. 5, 1925, Water Supplies, p. 50.—The Miami, Florida, supply is derived from 9 wells. It is treated with lime and alum, carbonated and filtered.

JACK J. HINMAN, JR.

Some features of filter design. J. W. ARMSTRONG. *Eng. News-Rec.* 95, 470-1(1925).—Since construction of Loch Raven Reservoir (Baltimore) max. 20° count has been reduced from 800,000 to 13,000 per cc. and max turbidity from 5000 to 200 p.p.m. Max. temp. has been reduced 6° F. To obtain max. efficiency with coagulation the water should be violently agitated immediately after addition of coagulant. Later agitation is ineffective. Expts. carried out at Baltimore with mixing basins of around-the-end type with 13-180° turns showed a distinct gain in subsiding value of the water at each successive turn. Reinforced concrete in contact with water has been found to have a tendency to disintegrate, particularly in cold climates, two important factors being quality of sand and imperviousness of concrete. Seepage of water through concrete, particularly where subject to frost action, will lead to ultimate disintegration. Water of p_H value less than 7.5 and alk. less than 100 dissolves CaCO_3 from concrete, and Al compds. also slowly go into soln., resulting in loss of strength; rapidity of destruction depends largely on porosity.

R. E. THOMPSON

Keeping the filter plant up to the mark. A. O. TRUE. *Fire and Water Eng.* 78, 791-2 and 820(1925).—Practical plant details.

JACK J. HINMAN, JR.

Rapid filters of the Stuttgart, Wurtemberg, water works. BAER. *Z. des Vereins deut. Ingenieure*, June 6, 1925; *Génie civil* 87, 339(1925).—Water from the Neckar is submitted to prefiltration, put through sand filters and chlorinated.

J. J. H., JR.

Electrically operated gages devised for filters. H. N. JENKS. *Eng. News-Rec.* 95, 346-8(1925).—Loss-of-head gages and valve-opening indicators consisting of voltmeters actuated by current varied through reactance coils, developed at Sacramento filtration plant, are described and illustrated.

Sewage disposal—Retrospective and prospective. T. SALKFIELD. *Surveyor* 67, 29-30(1925).

Sewage disposal. ANON. *Surveyor* 67, 92-6(1925).—Review of progress 1924. R. E. GREENFIELD

Newark (England) sewage disposal. W. H. RADFORD. *Water and Water Eng.* 27, 234-6(1925).—Sewage is first settled and the sludge removed and dried on beds. The sewage is then mixed with 2½% activated sludge and stirred for one hr. After mixing the sludge is removed by settling and pumped to a reconditioning (aeration) tank and the liquid is run to the river. The sewage is 20% brewery waste and it is hard to get an activated sludge. The plant is run 16 hrs. per day. J. J. H., JR.

● Sewage disposal in the Rhenish-Westphalian industrial district. SIERP. *Z. Nahr. Genusssm.* 50, 53-69(1925).—A report, illustrated with photographs and diagrams. WILLIAM J. HUSA

Summary of the subject of the purification of sewage (in France). F. NAVE. *La technique sanitaire* 20, 157-64, 183-7(1925).

Activated-sludge process of sewage purification. G. P. HEAD. *Pub. Health J. (Can.)* 16, 82-5(1925).—The activated-sludge process is described and discussed and its advantages are outlined. R. E. THOMPSON

Report of Committee on Sewerage (in Wisconsin). F. R. KING, *et al.* *Proc. Eng. Soc. Wisc.* 17, 156-60(1925).—New sewer systems and treatment plants in the state since the 1924 report. Cf. C. A. 19, 2992. JACK J. HINMAN, JR.

Sewage works for small districts. J. D. WATSON. *Munic. Eng.* 76, 8(1925).—Sewage treatment methods suitable for small communities are outlined and discussed. R. E. THOMPSON

New sewage purification works for Epson. ANON. *Surveyor* 68, 315-6(1925).—Consists of detritus tanks, sedimentation tanks and aerating tanks using simplex aerators. Sedimentation takes place in quiet zones thus automatically returning the sludge. The power required is 725 h. p. for a 500,000 gallon flow. R. E. G.

Sewage treatment plant operation. G. H. RADEBAUGH. *Proc. Ills. Soc. Engrs.* 40, 63-7(1925).—Design and operation data on plant of Urbana-Champaign district consisting of coarse screens, Imhoff tanks, sprinkling filters, sludge-drying beds and lagoon. JACK J. HINMAN, JR.

Sewage pollution of drinking water for cattle and its effect on them. A. LEVIE. *Veterinary Record* 5, 692-3(1925).—Drinking sewage-polluted water causes loss of appetite, unthriftiness, drowsiness, weariness, scouring and sometimes vomiting. Septic swellings of the throat are occasional. Cattle kept solely on water contg. a high proportion of crude sewage will die in about six months. Recovery on clean water requires about 3 to 6 months. Toxins of sewage are important. Cattle drinking sewage-laden water are more susceptible to tuberculosis, Johnne's disease, and contagious abortion. JACK J. HINMAN, JR.

Measuring sewage flow by pitometer. A. L. SHAW. *Eng. News-Rec.* 95, 518(1925).—A device is described by means of which pitometer orifices may be flushed to remove adhering solids. R. E. THOMPSON

Recent additions to the sewerage system and disposal works of Framingham, Mass. F. W. HALEY. *J. Boston Soc. Civil Eng.* 12, 253-75(1925); *Pub. Health Eng. Abst.* Aug. 15, 1925, Sewage and Industrial Wastes, p. 48.—An installation of 12 acres for "intermittent filtration" and 57 acres for "broad irrigation" is supplemented by 2 Imhoff tanks with sludge beds and 16 sand filters of ½ acre area each. The Imhoff tanks are designed for 5000 people each and when operating at capacity will have a sedimentation period of 2 hrs. 10 min., and a sludge capacity of 2 cu. ft. per capita. Gas vents occupy 21% of the superficial area of the tanks. The sludge-beds have an area of 1 sq. ft. per capita. JACK J. HINMAN, JR.

Report on the installation of sewers and the propagation of worm infestations in British Guinea. H. KHALIL. *J. Helminthology* 2, 175-90(1924); *Sanitation Supplement, Tropical Disease Bulletin* No. 1, 45(Mar., 1925); *Bul. mens. office internat. d'hyg. publique* 17, 1014-6(1925).—In England and Europe most thought is given to bacterial content of sewage and waters. Worms, including hookworm, and protozoa are very important in the tropics. Hookworm larvae can pass through filter paper and through the human skin. Filtration is probably not effective against them. Septic tank action does not always kill hookworm larvae. JACK J. HINMAN, JR.

Activated-sludge works in East York. ANON. *Cont. Rec.* 39, 690-5(1925).—The new Don Valley sewage-disposal works of East York Township, adjoining Toronto, Ont., are described and illustrated. The plant, which is of the diffuser aeration activated-sludge type, consists of bar screens, detritus tanks, re-aeration and mixing tanks.

for intermixture of returned sludge and inflowing sewage, aeration tanks and Dorr clarifier, the effluent being discharged into the Don River. The excess sludge will pass to digestion tanks, and, after digestion, will be dried on beds consisting of 12 in. of gravel and 12 in. of screened ashes underlaid with agricultural tile. R. E. T.

The pressing of precipitated sludge. J. T. THOMPSON. *Surveyor* 67, 269-70 (1925); cf. C. A. 19, 2251—Method used at Leeds (Eng.). R. E. GREENFIELD

Reading new activated-sludge plant. ANON. *Surveyor* 67, 249-50 (1925).—Brief engineering description. R. E. GREENFIELD

The subject of septic tanks in the Department of the Seine. VAILLARD. *Comptes rendus Conseil d'hyg. publ. et salubrite du Dept. de la Seine* 31, 66 (1925); *Bul. mens. office internat. d'hyg. publ.* 17, 928-9 (1925). JACK J. HINMAN, JR.

Remodeling an old septic tank and constructing a separate sludge-digestion and sprinkling filter system for the city of Rochelle, Illinois. R. I. RANDOLPH. *Proc. Ills. Eng. Soc.* 40, 68-71 (1925). JACK J. HINMAN, JR.

Wandle Valley joint sewerage board. *Munic. Eng.* 76, 380 (1925).—The Wandle Valley works, treating dry weather flow of 3,900,000 gallons per day from population of 80,000, consists of primary and secondary sedimentation tanks, percolating filters and humus tanks, the effluent being discharged into the River Wandle. The sludge is mixed with ground lime, pressed at 80 lbs. pressure, and disposed of for fertilizer. R. E. THOMPSON

The correlation of federal health agencies. L. R. WILLIAMS. *J. Am. Med. Assoc.* 85, 1479-80 (1925).—The present federal bureaus have overlapping agencies and lack of correlation. Under the present conditions many improvements are possible, but so far no comprehensive plan has been worked out. L. W. RIGGS

The Sanitary Inspectors' Association of Canada. L. L. ANTHES. *Pub. Health J. (Can.)* 16, 135-42 (1925).—The fundamentals of sewage treatment in septic tanks are outlined and discussed. R. E. THOMPSON

Continuous carbon monoxide recorder in the Liberty Tunnels. A. C. FIELDNER, S. H. KATZ AND E. G. MEITER. *Eng. News-Rec.* 95, 423-4 (1925).—A CO recorder which has been successfully employed in controlling ventilation in the Liberty Tunnels, Pittsburgh, for 10 months is described and illustrated. The principle involved is the measurement by thermocouples of the increased temp. of gas when CO and O₂ react in the presence of a catalyst, the thermoelec. effects being recorded by means of a potentiometer which is sensitive to 1-2 parts per million. Four parts of CO per 10,000 parts of air has been detd. to be the max. concn. to which human beings may be exposed continuously for 1 hr. without noticeable effect, or, if concn. is increased from zero uniformly for 1 hr., max. tolerable concn. is 6 parts per 10,000, averaging 3 parts for the hr. R. E. THOMPSON

How to make a sanitary survey of your plant. C. L. FERGUSON. *Ind. Eng. Chem.* 17, 1275-7. —One should become acquainted with the standards for cleanliness, drinking water, ventilation, lighting, toilets, cuspidors, wash rooms, dressing and rest rooms and restaurant, as they pertain to the plant. Expert advice should be sought whenever necessary. EDWARD BARTOW

Public swimming pools in the city of Edmonton. ANON. *Cont. Rec.* 39, 654-5 (1925). —The water is circulated every 18-24 hrs. and is purified by filtration and chlorination with bleach, the latter being controlled by the o-tolidine test. CuSO₄ is used in small quantities to control algal growths. R. E. THOMPSON

The purification of swimming bath water. ANON. *Munic. Eng.* 76, 217 (1925). —The water of the municipal pools of St. Helens, of which there are 2 of aggregate capacity of 112,000 gallons, is filtered through Paterson pressure filters after addition of coagulant, aerated with compressed air, and chlorinated with Chloronome app. at the rate of approx. 0.5 p.p.m. The water is circulated at a rate equiv. to complete replacement every 10 hrs., and is heated to 72° F. in summer and 78° F. in winter. After 19 weeks' continuous use, examn. showed *B. coli* and *B. enteritidis sporogenes* to be entirely absent; the total no. of bacteria per cc. on gelatin, 3 days' incubation, was only 112. There was no trace of free Cl₂ or nitrites, and the free and albuminoid ammonia and $\frac{1}{2}$ absorbed in 3 hrs. at 37° were 0.0046, 0.0058 and 0.045 part per 100,000, resp. R. E. T.

A water-borne typhoid epidemic at Aegion, Greece. GEORGE SP. JOANNIDES. *La Grèce medicale* 27, 10 (1925); *Bul. mens. office internat. d'hyg. pub.* 17, 907-8 (1925). —An epidemic of 128 cases and 2 deaths in Nov., 1924. Water of the aqueduct was polluted at the point of entrance to the reservoirs. The distribution of water was stopped, repairs were made and the reservoirs treated with lime. JACK J. HINMAN, JR.

Algal growths in tank waters. V. G. RAJU. *Water and Water Eng.* 27, 57 (1925). —

Algae seem to prefer a temp. of about 75° F. and die off as reservoirs get low and the water goes above that value in temp. They then decompose and give off bad odors. Copper sulfate and lime have not been very effective under Indian conditions. H_2SO_4 in amt. necessary to neutralize the bicarbonates has been very successful. It is not necessary to add the dose all at once. Most important algae have been *Oscillaria*, *Anabaena*, *Cylindrospermum*, *Navicula*. A *Euglena* forms a thick red coating at times on the water. *Spirogyra* is the most important layer form of alga. J. J. H., JR.

Soil acidity and survival of hookworm larvae. A. C. CHANDLER. *Indian Med. Gazette* 60, 462-4 (1925).—The acidity likely to be in agricultural soil, up to a p_H of 5.5, does not interfere with the survival of the hookworm larvae. L. W. RIGGS

● **Decomposition of "cobolt" or "metalloid arsenic" by atmospheric oxygen in presence of water.** MAURICE FRANÇOIS AND (MISS) LAURE SÉGUIN. *Ann. fals.* 18, 460-4 (1925).—The action of "cobolt" as a fly destroyer is due to the formation of sol. H_3AsO_3 by action of atm. O in presence of H_2O under ordinary conditions of use. In 34 days 30% of the As was obtained in sol. form, and it is concluded that it would ultimately be all solubilized. A. PAPINEAU-COUTURE

Air pollution. The tenth report of the London Advisory Committee on Air Pollution. J. B. C. KERSHAW. *Combustion* 13, 218-20 (1925).—Although the amt. of soot and solid combustion products suspended in the atm. seldom amounts to 1% of the weight of the coal burned, its presence is a sign of bad conditions of combustion, and considerably more than 1% of the calorific value of the coal is lost under these conditions. Impurities in the atm. also contaminate the rainfall. Data on the impurities in rainfall and the total fall of solid matter in towns in the United Kingdom are given. J. F. BYRNE

Cemeteries and cremation. FR. MESSERLI. *La Technique sanitaire* 20, 65-71 (1925).—Discusses decomposition of cadavers and relation to nature of soil of burying ground, ground water height and hygiene. Cremation is favored on ground of economy as well as on that of hygiene. JACK J. HINMAN, JR.

The classification of common salt by its iodine content and the use of iodine in combating goiter (RÓZSA) 11G. Corrosion (TRAX) 9.

ADAMS, H. C.: **Domestic Sanitation and House Drainage.** 227 pp. Henry Froude and Hodder and Stoughton: London. Reviewed in *Expt. Sta. Rec.* 53, 188 (1925); *Public Health Eng. Abst.*, Sept. 26, 1925, Sewage and Industrial Wastes, p. 51.

Electrolytic protection of surfaces of steam boilers or other metals against incrustation. W. THALHOFFER. U. S. 1,558,646-7, Oct. 27.

Fumigating with hydrocyanic acid. W. S. LANDIS AND G. H. BUCHANAN. U. S. 1,559,892, Nov. 3. After introducing HCN gas into a space to be fumigated, NH_3 and AcH are introduced (in the proportions of substantially more than 1 mol. NH_3 to $1\frac{1}{4}$ mols. of the AcH) to destroy the HCN.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

A bibliography of soil alkalies. F. V. KING, GUY ERVIN AND O. LOUISE EVANS. U. S. Dept. Agr., *Bull.* 1314, 1-40 (1925).—A bibliography compiled with special reference to the deleterious action of soil alkalies and various other chemical agents on cement and concrete. W. H. ROSS

The nature of soil acidity. D. J. HISSINK AND JACOB VAN DER SPEK. *Chem. Weekblad* 22, 500-1 (1925).—Soil particles are negatively charged in aq. suspension. It is assumed that they carry a double elec. layer, the positive inner, consisting of aluminosilicate or humic acid anions, the negative outer layer of H, K, Na, Ca and Mg ions. The H ion of the double layer and that of the molecularly dispersed acids determine the acidity of the soil. Clay acids are weak, humic acids mostly weak, sometimes moderately strong. The decrease of acidity with diln. is explained by a smaller no. of colloidal particles with double layer. The interpretation is supported by the lower acidity of centrifugates or filtrates as compared with the original suspensions and the increase of p_H from 4.2 to 4.6 in soil suspensions as soon as the rotation of the electrode ceases. The origin of the negative charge of the particles is sought not in the stronger adsorption of H ion but in the splitting off of cations by the boundary layer. M. J.

The nitrifying power of pozzolanas. I. CESARE SERONO AND LAURA GUERCI.

Ann. chim. applicata 15, 309–16(1925).—Systematic analyses of various waters originating in volcanic ground, particularly in the subsoil of Rome where pozzolana is present, showed the presence of nitrates but no nitrites or NH_3 . Four samples from the region of Rome contained 0.1320, 0.0988, 0.0844 and 0.0302 g. of N_2O_5 per l., the amts. remaining approx. const. for months. Bacteria and org. substances were absent and the nitrates were of *inorg. origin*. Since pozzolana is a transformation product of volcanic rock and since NH_4 salts dissociable at low temps. are present in such eruptions, it is probable that the nitrates were formed from these NH_4 salts and air by the catalytic action of pozzolana. To verify this supposition, expts. were made to det. whether NH_3 can be oxidized by air with pozzolana as catalyst. When a current, hot or cold, of a mixt. of NH_3 and air was passed through pulverized pozzolana and H_2O , a small amt. of NH_3 was oxidized to N_2O_5 , the latter being formed whether or not the pozzolana had been sterilized with CHCl_3 . On the other hand there was no N_2O_5 formed with pozzolana which had been calcined, nor with that which had been heated at 250° for 2 hrs., these last tests being to det. whether the colloids present in pozzolana were the active catalytic agent. Nor was any N_2O_5 formed with pulverized pumice, indicating as did the expts. with calcined pozzolana, that the formation of N_2O_5 is independent of the extent of the surface of contact. The formation of *Chile nitrate*, which occurs in a volcanic region, may have originated in the same manner as the nitrates in the H_2O of the volcanic ground described. The presence of nitrates in the H_2O of volcanic regions explains why the addn. of N fertilizers to the Roman campagna does not increase the yield of crops, for nitrates are supplied in adequate quantity in the H_2O . C. C. DAVIS

Humophosphates. E. BORTINI. *Ann. chim. applicata* 15, 358–62(1925).—The work of Berthelot, Grandeau (*Ann. station agronom. de l'est* 1878), Dumont (*Les matières humiques du sol*, Paris 1905, 117) and Petit (*C. A.* 5, 2684) left in doubt the nature of the absorption of P_2O_5 by humus and whether it even involves a chem. reaction. Repeating the expts. of Dumont, but using peat, a humate was obtained which contained 5.98% P_2O_5 and 3.19% N, a result similar to that of Dumont. A study was then made to det. what component of humus absorbs P_2O_5 , i. e., whether it is the true humic acids, aliphatic or aromatic acids (crotonic, dihydrostearic, agroceric, cinnamic, etc.), org. bases (purine, xanthine, guanine, etc.) or inorg. bases. **Humic acids.**—Two artificial humic acids were prepd from hydroquinol and from pyrocatechol, resp. (cf. Eller and Koch, *C. A.* 15, 83). The preps. were then repeated, except that previous to the oxidation by $\text{K}_2\text{S}_2\text{O}_8$, $\text{Ca}(\text{H}_2\text{PO}_4)_2$ soln. was added. Analysis of the 4 humic acid products showed the absence of P_2O_5 in all. **Org. acids.**—Crotonic and cinnamic acids were chosen as typical. Even after a month neither reacted with H_3PO_4 , the latter being used rather than $\text{Ca}(\text{H}_2\text{PO}_4)_2$ to avoid Ca ppts. **Org. bases.**—Guanine and hypoxanthine when treated in alk. soln. with $\text{Ca}(\text{H}_2\text{PO}_4)_2$ gave white ppts. contg. P_2O_5 in each case. When treated with dil. H_3PO_4 , however, the ppts. contained no P_2O_5 . **Inorg. bases.**—Expts. proved that the KOH used to dissolve the humic acids was the active agent in the absorption of P_2O_5 ; in fact dil. KOH and $\text{Ca}(\text{H}_2\text{PO}_4)_2$ soln. formed a ppt. contg. P_2O_5 , which calens. showed accounted for practically all the P_2O_5 absorbed by the humic acids. It is concluded that the so-called "humophosphate" is not a definite chem. compd. but is a *Ca humate accompanied by more or less CaHPO_4 and $\text{Ca}_3(\text{PO}_4)_2$* formed by the action of the alkali used as a solvent of the humic substance. C. C. DAVIS

Influence of easily soluble nitrogenous compounds on the decomposition of cellulose in the soil. J. A. ANDERSON. *Kgl. Landtbr. Akad. Handl. och Tidskr.* 64, 199–509(1925).—The rate of decompn. of cellulose in soil increases in proportion to the assimilable N present until this exceeds the quantity necessary for the max. development of the microorganisms. Under the conditions of the expts. this point was reached when the ratio between assimilable N and cellulose was 1:35. N in excess of this was without influence on the decompn. The quantity of cellulose decomposed per mg. N decreases with increased quantities of N. Nitrification takes place in the soil in the presence of cellulose, but unless more N is present than needed by the microorganisms, the nitrate N is consumed as soon as formed. Ammonification also takes place in the presence of cellulose. It appears that none of the bacteriol. processes in soil is stopped by the addition of carbohydrates. When cellulose is added to soil, conditions are created for the development of cellulose-decomp. organisms and these in turn use for their growth the assimilable N. The growing plant is not able to compete with the microorganisms for the N and hence are hindered in their development or fail entirely. C. O. SWANSON

The nitrogen compounds in rain and snow. F. T. SHUTT AND B. HEDLEY. *Trans. Roy. Soc. Can. Sec. III* [3], 19, 1–10(1925); cf. *C. A.* 11, 1242.—This investigation ascertained the fertilizing value of rain and snow in nitrogenous plant food over the period

1907-1924. The rain was collected in a lead-lined tray, the snow off a stone ledge on the chemical building, Experimental Farm, Ottawa. Samples were collected twice daily during precipitation. During the 17 years, 1214 samples of rain and 495 of snow were analyzed for NH_3 , albuminoid NH_3 , nitrates and nitrites. The av. annual rainfall was 24.15 inches and snowfall 95.7 inches. There was no direct proportionality between the vol. of rainfall or snowfall and the quantity of N furnished annually per acre. Bush fires in 1908-09 gave an abnormally high NH_3 content. The av. annual contributions of N in lb. per acre, for rain and snow, resp., was: as free NH_3 3.322, 0.568; as albuminoid NH_3 0.654, 0.194; as nitrates and nitrites 1.762, 0.412. The investigation is being discontinued because of the increasingly large amount of ammonia found and attributed to the use of bituminous coal in the neighboring city of Ottawa. J. W. SHIPLEY

Manufacture and analysis of the new ureic fertilizers obtained from cyanamide.

A. COCHET. *Ann. fals.* **18**, 396-412, 468-76(1925); cf. *C. A.* **18**, 3246—The manuf. of urea, "phospho-N" and other ureic fertilizers as carried out at the Martigny plant of the Société des Produits Azotés is briefly outlined. In the *detn. of urea* via Fosse (*C. A.* **8**, 1972, 3181, 3450): (1) an excess of at least 2.8 times the theoretical quantity of xanthidol is required; (2) a 50% reduction in the indicated concn. of AcOH still gives quant. pptn. of $\text{CO}(\text{NH}_2)_2$, while increase in the concn. gives incomplete pptn.; (3) by adding the 5 cc. of xanthidol soln. at one time, the duration of pptn. can be reduced to 1 hr. 15 min.; (4) counterpoised filters can be used instead of a Gooch crucible, and drying is much quicker; (5) drying is incomplete at 110° , all the AcOH is driven off in 50 min. at 150° . In the presence of guanilylurea sulfate, $(\text{NH}_4)_2\text{SO}_4$ and superphosphate, shake 30 min. with water, make slightly alk. with NaOH with phenolphthalein indicator, make to vol., filter and det. urea in an aliquot. On account of the small amt. of sample which must be taken (not over 20 mg. $\text{CO}(\text{NH}_2)_2$) the results are usually somewhat low as a result of errors in measuring; but practically theoretical results are obtained by weighing the aliquot taken and calcg. its vol. from the d. of the soln. taken with a picnometer. For the *detn. of guanilylurea*: to 10-15 cc. of soln. contg. not over 0.125 g. of guanilylurea-N add successively 0.1 g. of mannitol per cc. of soln., about 20 cc. of Ni reagent ($\text{Ni}(\text{NO}_3)_2$ 10 g., NH_4NO_3 5 g., H_2O 50 cc., concd. NH_3 aq. 20 cc., 10% NaOH 20 cc.) and 4 cc. 10% NaOH , let stand 4 hrs., filter on a Gooch crucible, wash with 2% NH_3 till free from Ni , dry to const. wt. and weigh. The standing beakers should be covered to prevent loss of NH_3 with consequent pptn. of $\text{Ni}(\text{OH})_2$; but if the latter occurs, redissolve with a little NH_3 . The compn. of the ppt. is $\text{Ni}(\text{C}_2\text{H}_5\text{ON})_2 \cdot 2\text{H}_2\text{O}$, and not $\text{Ni}(\text{C}_2\text{H}_5\text{ON})_2 \cdot \text{H}_2\text{O}$ as claimed by Grammont; on drying at 100° it loses $2\text{H}_2\text{O}$, so that the factor is 0.42968, and not 0.4019 as claimed by Grammont. With small guanilylurea contents, the ppt. is merely weighed after drying, but with high contents N is detd. in the ppt. *via* Kjeldahl. In the presence of urea, $(\text{NH}_4)_2\text{SO}_4$ and superphosphate, shake 30 min. with H_2O , make slightly alk. to phenolphthalein with NaOH , make to vol., filter, take an aliquot and make slightly acid to Me orange, evap. to about 15 cc. (adding H_2SO_4 if necessary during evapn. to keep acid), add 2 g. of mannitol, and ppt. with Ni as above. For the *detn. of NH_3 -N* the Ronchèse method (conversion to $(\text{CH}_2)_6\text{N}_4$ by means of CH_2O) and Auger's method (*C. A.* **18**, 1798) are inapplicable because of partial electrolytic dissociation of the guanilylurea sulfate. It is detd. by treating a soln. of the sample with 30 cc. of 36° Bé. NaOH in the cold, and drawing off the liberated NH_3 into standard H_2SO_4 by means of a current of air. All the NH_3 is removed in 2.5-4 hrs. In the *detn. of dicyanodiamide* *via* Harger (*C. A.* **15**, 286) optimum conditions are: not over 0.05 g. of dicyanodiamide-N in 100 cc., 0.150 g. AgNO_3 (as 5% soln.), 100 cc. of picric acid (7.5 g. per l.). Addn. of more than 0.150 g. of AgNO_3 is liable to cause partial pptn. of Ag picrate or of Ag-NH_3 picrate (when NH_3 is present). In cyanamide, $\text{C}_2\text{N}_4\text{H}_4$ is first extd. with Me_2CO in a Soxhlet app. for 1 hr., the ext. evapd. almost to dryness, taken up with H_2O and treated *via* Harger. If the cyanamide is extd. with alc. instead of Me_2CO , the H_2O in the alc. dissolves free CaO from the cyanamide and polymerizes part of the latter to $\text{C}_2\text{N}_4\text{H}_4$, giving high results. The method was applied to com. "phospho-N" and showed it to be free from $\text{C}_2\text{N}_4\text{H}_4$. When applied to a sample contg. a known added amt. of $\text{C}_2\text{N}_4\text{H}_4$, the whole of the latter was recovered. $\text{C}_2\text{N}_4\text{H}_4$ should not be calcd. by difference.

A. PAPINEAU-COUTURE

May Chile saltpeter be replaced by other nitrogenous fertilizers? JULIUS STOKLASA. *Z. Zuckerind. cecoslov. Rep.* **50**, 17-21, 25-9(1925).—Pot expts. with sugar beets gave results as follows: wt. roots (a), wt. leaves (b), % sugar (c), wt. sugar per 10 pots (d)—no fertilizer, (a) 2364, (b) 894, (c) 16.2, (d) 383 g.; base fertilizer (monocalcium phosphate and kainite), (a) 2407, (b) 958, (c) 18.6, (d) 448; base + NaNO_3 , (a) 4070, (b) 1960, (c) 18.0, (d) 733; base + KNO_3 + NH_4NO_3 , (a) 3825, (b) 2060, (c) 17.9, (d) 685; base + "ammonium sulfate-nitrate," (a) 3572, (b) 1820, (c) 17.2, (d) 614; base +

(NH₄)₂SO₄, (a) 3603, (b) 1547, (c) 17.3, (d) 623. Similar results were obtained with oats. Comparative pot expts. with and without 21 mg. KI per pot showed largely increased yields with KI. This is held to be the reason for the superiority of Chile saltpeter over all other nitrogenous fertilizers.

The maturation of horse manure. E. BOTTINI. *Ann. chim. applicata* 15, 346-57 (1925).—Because of its agricultural importance, analyses of horse manure were made each 2 months as it reached more advanced states of decompn. The material was kept in a moist condition by replenishing the H₂O lost, thus insuring normal microbic action. Cellulose is very resistant during the early stages of maturation but then decomps. rapidly and after 4 months it is reduced to 40% and after 8 months to 26% of the original amt. The proteins are likewise very resistant, but exact data are difficult to obtain because of the action of bacteria which fix N and compensate the loss, and which become active after about 2 months. The fatty substances decrease noticeably during the first 2 months, this decrease becoming more rapid in the succeeding 2 months. The loss is thereafter gradually more than compensated by the formation of fats from the decompn. of cellulose and of proteins, which occurs after about 6 months. The penosans decomp. gradually from the beginning, and after 8 months only about 16% remain. The methyl-pentosans also decomp. from the beginning, but this decompn. ceases after 6 months, at which time about 40% remain. The mineral substances change but slightly or not at all. Other unidentified substances take part in the maturation, their decompn. contributing to a further progressive loss of wt. A review of the compn. of manure and the chem. reactions involved in its decompn. is included. C. C. D.

Some effects of sodium arsenite when used to kill the common barberry. P. R. SCHULZ AND N. F. THOMPSON. U. S. Dept. Agr., *Bull.* 1316, 1-18 (1925).—Na₃AsO₃ in proper diln. is an effective killing soln. for most plants and is found in nearly all tissues of treated plants while controls contain no As. The soln. is most effective in killing plants when applied to the roots; spraying or dipping is not always effective. When rainfall was abundant the soils used showed rapid leaching of Na₃AsO₃ but its sweet taste attracts animals and its use in pastures without precautions or repellents is therefore unsafe. A modified volumetric method was developed for the detn. of small quantities of As in plant tissue. A bibliography of 8 references is appended. W. H. ROSS

Preliminary studies on the control of cereal rusts by dusting. C. V. KIGHTLINGER. *Phytopathology* 15, 611-3 (1925).—A sulfur dust contg. 10% Pb arsenate was used in greenhouse and plot expts. for controlling *Puccinia coronata* on oats artificially inoculated by spraying with spore suspensions or interplanting with infected plants. Four applications gave almost absolute control, untreated checks having 74% infection. The work is being continued and extended to other cereals. JOSEPH S. CALDWELL

Influence of temperature and humidity upon the volatilization of nicotine from tobacco dust-lime hydrate mixtures. L. R. STREETER. *J. Econ. Entomol.* 18, 590-3 (1925).—Moisture is more important than temp. in the volatilization of nicotine. The addn. of a little water to the mixt. insures a rapid evolution of nicotine. C. H. R.

Observations on insects developing immunity to insecticides. R. S. WOGLUM. *J. Econ. Entomol.* 18, 593-7 (1925).—In certain districts of Calif., the red and black scale have developed immunity to HCN to such an extent that present dosages are unreliable. C. H. R.

Determination of nitrate N (LAGERS) 7.

Nitrogenous fertilizer or stock feed. L. F. SCHMELZER. U. S. 1,561,667, Nov. 17. Materials such as garbage or slaughter house materials are digested in a heated closed steam-tight container, in steam derived at least mainly from the moisture in the material itself.

Product from sulfur and alkaline protein compounds. W. C. PIVER. U. S. 1,559,984, Nov. 3. Pulverized S is dispersed in an alk. protein compd. such as that of NaOH and casein to prep. a finely comminuted product suitable for use as a fungicide.

"Pickling" seeds. CHEMISCHE FABRIK L. MEYER. Brit. 232,563, April 19, 1924. Seeds are protected against fungoid diseases, etc., by a mixt. of HgCl₂ or other Hg compd. with phenol, with or without kaolin, fossil meal or alcs. Brit. 232,564 specifies the use, for the same purpose, of formalin with glycerol, HCl, glycollic acid nitrite, phenol, MgCl₂ or HgCl₂, with or without inert substances.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Preliminary investigation on the ultimate possible commercial uses of the leaves of *Opuntia vulgaris* (India fig-tree). HURDISAN. *Bull. assoc. inst. sup. ferm. Gand* 26; *Ann. soc. brasseurs* 34, 284-99 (1925).—Analysis of the pulped leaves gave: H_2O 82.79, total solids 17.21, ash 3.67, org. matter 13.54. The compn. of the org. solids calcd. to the dry basis was found to be: hexoses (calcd. as glucose) 3.62, crude protein ($N \times 6.25$) 9.63, sol. uncoagulable proteins (albumin II) 1.04, albumin I 4.48, propeptones 1.28, denucleins 0.83, peptones 1.99, Et_2O ext. 0.26, petr. ether ext. 0.12, gums and dextrins 44.67, crude fiber 37.43%. The ash contained (on the wet basis) SiO_2 0.27, P_2O_5 0.45, MgO 0.18, CaO 0.72%. Extn. in the cold (about 15°) and hot (about 80°) of 50 g. of the pulp with 450 g. H_2O dissolved 2.89 and 4.96%, resp.; with 445 g. H_2O and 5 g. H_2SO_4 dissolved 6.05 and 7.65%, resp.; with 445 g. H_2O and 5 g. $NaOH$ dissolved 3.89 and 7.00%, resp. The juice had p_H 4.3. The pulp contains a proteolytic diastase active at about $45-50^\circ$, a dextrin-saccharifying diastase, oxidizing diastases (laccase, tyrosinase, or perhaps a peroxidase), but no liquefying diastase. The sugars consist of glucose, or xylose, or a mixt. of both. The juice contains the glucoside of an acid, possibly an allotropic form of primeverin. On placing a small piece of the bark of the leaves in unhopped beer worts having p_H of (1) 4, (2) 6, (3) 7.4, resp., there developed mainly: (1) and (2) a yeast with small ovoid, *Torula*-like cells, and small motile rods; (3) large cells with rounded corners, forming zoögleas, apparently identical with Lindner's *Sachsis suaveolens*. Boiled, filtered and sterilized wort at 8.4° . Balling was inoculated with pure strains from the 3 above cultures: (1) gave a slow fermentation with aromatic odor, and the distillate had the characteristic odor and b. p. of $PrOH$; (2) gave rapid fermentation with decided butyric odor; the distillate was practically odorless and the residue had a strong butyric odor; (3) gave a slow fermentation with odor of white wine, and the fermented liquor had an acid and strongly aromatic flavor.

A. PAPINEAU-COUTURE

The conversion of wood cellulose into sugar and alcohol. FOULON. *Wochbl. Papierfabr.* 56, 1149-51 (1925).—Wood, for conversion to sugar and $EtOH$, is best used in a disintegrated form which has been previously leached with water to remove sol. substances. HCl , in a closed system under pressure, is preferable to H_2SO_4 for the hydrolyzing agent. The various steps in the conversion process are described. The method of Classen, using H_2SO_4 , $50-60^\circ$ Baumé, is also given. Other patents of C. involve the use of Cl and hypochlorites, and H_2SO_4 contg. SO_3 . J. L. PARSONS

Evaporation losses in quick-vinegar producers. A. STEINMETZ. *Chem.-Ztg.* 49, 613-5, 635-6 (1925).—A discussion of advances in the manuf. of vinegar by the quick-vinegar process from $EtOH$. Large amts. of both $EtOH$ and $AcOH$ are often lost in the effluent air. The air used need not exceed about 3 times that required for the oxidation though it is usually not controlled and may reach ten times the theoretical. Analysis of the effluent air is often useful in indicating by too high an O content that a unit is not functioning properly. Over-oxidation, shown by the presence of too much CO_2 , is usually more quickly revealed by the cloudy appearance of the product. In recent times the effluent air is treated to recover $EtOH$ and various methods are discussed. The humidity and temp. of the air are shown to be factors in cooling and in evapn. losses, high humidities and temps. ($25-35^\circ$) causing smaller losses. M. A. Y.

Frings' capacity generators. HEINRICH FRINGS. *Deut. Essigind.* 29, 391-4, 396-7 (1925).—This type of generator is described and illustrated. W. O. E.

Antiseptic action of α -hop-bitter acid and its decomposition products on micro-organisms (WINDISCH, *et al.*) 11C. Preheating and spray desiccation of distillers' slop by combustion gases (U. S. pat. 1,558,022) 13. Rectification of alcoholic liquids (U. S. pat. 1,559,218) 22.

VENTRE, JULES: **Du rôle de l'acidité réelle dans la preparation et la conservation des vins.** Montpellier: Goulet et fils. 158 pp. Reviewed in *Ann. fals.* 18, 482-6 (1925).

FABRE, J. H.: **Procédés modernes de vinification en Algérie et dans les pays chauds.** Paris: Dujardin; Alger: J. H. Fabre. Reviewed in *Ann. fals.* 18, 486 (1925).

Acetone and butyl alcohol by fermentation. E. RICARD. U. S. 1,550,746, Aug. 25. In fermenting carbohydrate materials such as a cereal wort or saccharine soln. for

producing acetone and BuOH, successive relatively small quantities of a non-aseptic wort are added to an aseptic fermenting wort.

Alcohols and acetone by fermentation. E. H. STRANGE. U. S. 1,550,928, Aug. 25. Both yeast and bacteria capable of producing BuOH and acetone are used for the fermentation of a mash from cereals or other amylaceous materials or saccharine solns.

Enzymic beverage. J. TAKAMINE, JR. U. S. 1,561,955, Nov. 17. Beverages having diastatic and proteolytic properties are prepd. by isolating a H₂O-sol. enzymic compn. of vegetable fungus origin, *e. g.*, from *Aspergillus oryzae*, and mixing this enzymic material with dissolved cane sugar to produce a thick sirup suitable for diln. with H₂O.

Yeast. A. POLLAK. U. S. 1,558,627, Oct. 27. Materials such as leguminous flour, soja flour, oil cake, cereal seeds, bran, grains, dry yeast or any vegetable protein materials, or casein, fibroin, collagen, meat meal, etc., may be used for prepg. nitrogenous yeast-nutrient substances; *e. g.*, a part of the raw material may be made into a thick mash with H₂O, and then enough H₂SO₄ added to equal 5–15% of the total mixt. and the mixt. is heated to 100–110° for 3–12 hrs. to effect soln. of the protein substances. The action of the H₂SO₄ is then checked, *e. g.*, by adding an equiv. amt. of Ca phosphate, and is further heated at about 100° for about 12–24 hrs. or until tests show that the higher "albumen complexes" are converted into amino acids, peptones and albumoses. The soln. is treated with NH₃ to neutralize nearly all the acid then present and, after sepn. from insol. substances, is suitable for use. Other details are specified.

Yeast mixture. M. E. NEIL. U. S. 1,557,764, Oct. 20. A mixt. stated to possess good durability comprises moist compressed yeast 2, milk powder 2 and cooked arrow-root powder 0.125 part, with sufficient H₂O to facilitate admixture.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Future research in the field of organic arsenicals. W. G. CHRISTIANSEN. *Ind. Eng. Chem.* 17, 1270–1 (1925). E. J. C.

A new method for the determination of phenols in essential oils. L. RETI. *Ann. chim. applicata* 15, 317–20 (1925).—For a description of the method see *C. A.* 19, 1928. Typical results with oils included the following: thyme, 36% thymol; marjoram, 65% carvacrol; *Satureia montana*, 49% carvacrol; clove, 82% eugenol; pimento, 63% eugenol; Ceylon cinnamon, 14% eugenol. When an oil contains such a mixt. as eugenol and acetyleneugenol, *e. g.*, clove, which should both be detd. as phenols, the dil. NaOH should be added at 70–80°, under which conditions sapon. of the acetyl deriv. to eugenol is complete. The method may be extended to the detn. of basic compds. in neutral mixts., *e. g.*, pyridine and quinoline, by the use of 20% HCl as absorbent. C. C. DAVIS

New ampules. G. E. DANN. *Pharm. Ztg.* 70, 1520–2 (1925).—Five different types of the more recent multiple-chambered ampules are illustrated and described in detail. W. O. E.

Impregnated gauzes. P. SCHÜTZ. *Pharm. Ztg.* 70, 1522 (1925); cf. *C. A.* 19, 2861.—The analytical findings of a series of gauzes medicated with dermatol, Bi subgallate and xeroform are presented in tabulated form showing the declared and actual drug content of the fabric, the variations being such as to warrant more stringent control. W. O. E.

Strontiuran as solvent and reagent for arsphenamine and neoarsphenamine. ALFRED HIRSCH. *Pharm. Ztg.* 70, 1577–8 (1925).—Expts. are described showing how with the aid of "strontiuran" (a prepn. of SrCl₂ and urea, proportions not given) arsphenamine and neoarsphenamine may be applied in medical practice without fear of intoxication. 0.2 g. samples are dissolved in 100 cc. of H₂O, acidified with 25 cc. of 1:20 HCl, and treated with 50 cc. of 0.1 N I soln. After 3 min. the mixt. is titrated with 0.1 N Na₂S₂O₃ in the presence of starch. The no. of cc. of I soln. expended $\times 5$ = the total reduction capacity of 1 g. of the sample. This value should range between 152 and 160; the use of a product with a value of 149 to 150 is permissible, while those having lower values should be regarded with suspicion, and preferably discarded. W. O. E.

Strontiuran as reagent for neoarsphenamine and arsphenamine. W. KOLLE, H. BAUER AND F. LEUPOLD. *Pharm. Ztg.* 70, 1614–5 (1925).—The utility of strontiuran as a reagent in judging the quality of neoarsphenamine and arsphenamine, as advocated in the preceding abstr., is seriously questioned; in fact the results obtained and conclusions arrived at by Hirsch are shown to be illusory and based on false assumption. A more detailed publication of the authors' findings is shortly promised. W. O. E.

Examination of some Rhodesian eucalyptus oils. P. G. CARTER AND JOHN READ. *J. Soc. Chem. Ind.* **44**, 525-6T.—In the great majority of instances the material heretofore examd. was obtained from trees growing in their natural environment, comparatively little information of the kind now reported being available for material derived from cultivated trees. In the present instance small quantities of the 1st specimens of eucalyptus oils were distd. from 2 to 3 year old seedlings grown in the central region of Africa. In all cases the crude oils were dried with anhyd. Na_2SO_4 and filtered before examn. The values in parentheses represent findings for similar Australian products. *Eucalyptus macarthurii*.—Yield 0.32% (0.21), n_D^{15} 1.4821 (1.476 to 1.4718), α_D^{15} 4.1° (1.2 to 3.6), d_4^{15} 0.9329 (0.9214 to 0.9245); *E. citriodora*.—Yield 1.6% (0.8), n_D^{15} 1.4595 (1.4515 to 1.4596), α_D^{15} 3.5° (—1.0 to +1.7), d_4^{15} 0.8787 (0.8657 to 0.8697); *E. globulus*.—Yield 1.25% (0.92), n_D^{15} 1.4695 (1.4663), α_D^{15} 3.56° (8.4), d_4^{15} 0.9389 (0.913). The first named oil was almost colorless, contg. 57.1% of ester calcd. as geranyl acetate, as compared with 60 to 70% for Australian specimens. The free alc. calcd. as geraniol amounted to 5%. On keeping the crude oil deposited a large quantity of eudesmol, becoming ultimately almost solid. The *citriodora* product was almost colorless and contained 95% aldehyde, thus corresponding closely to Australian values. The oil from *E. globulus* was practically colorless, contg. *via* the H_3PO_4 method 65% of cineole, a value very like that for the Australian product. The results obtained indicate that although the Rhodesian and Australian oils exhibit appreciable difference in phys. consts., they nevertheless contain sensibly identical amts. of the main components of com. value, with the exception that the ester content of *E. macarthurii* oil is distinctly low.

W. O. E.

Veronal-pyramidone and "Veramone." HEINRICH RHEINBOLDT AND MARIETTE KIRCHSEIN. *Arch. Pharm.* **263**, 513-8(1925).—Examn. of varying mixts. of veronal with pyramidone by the "thawing and melting" method shows that veramone, alleged to consist of 2 mols of pyramidone and 1 mol. of veronal, is in reality a mixt. of the compd. $\text{C}_{21}\text{H}_{23}\text{O}_4\text{N}_2$ (veronal and pyramidone in equimol. proportion) with pyramidone, colored more or less yellow by decompn. (oxidation) products.

W. O. E.

Influence of alkali in hemolysis experiments on drug extracts. K. A. KARSMARK AND L. KOFLER. *Pharm. Zentralhalle* **66**, 717-23(1925).—In a study of this question 2 points were considered: (1) influence of alkali addn. on the extn. of saponins and other drug components; (2) influence of alkali on the final outcome of the hemolysis. For the proper clarification of the 1st point a great no. of expts. will be required involving a variety of saponin drugs in varying degrees of fineness. In this connection also some consideration must be given the influence of H-ion concn. To this end expts. are still in progress. In the present paper numerous expts. are described involving rat blood and various preps. of *Polygala* and Senega, while saponinum pur. albiss. Merck served as test object. It is shown that addn. of Na_2CO_3 in moderate amt. to the finished decoction of Senega depresses the hemolytic index, while larger amts. of alkali inhibit hemolytic action completely. That this is not due to hydrolysis is shown by electro-dialyzing the liquid thus treated, whereupon the hemolytic action of the dialyzate is regenerated. A decoction of *Polygala amara* prepd. without Na_2CO_3 reacting strongly acid was, by subsequent addn. of alkali, made to show any desired index from 1:260 to 0. Very min. quantities of Na_2CO_3 , insufficient to neutralize the decoction, depressed the hemolytic index. The explanation for the exptl. findings is believed to be found less in the chem. influence of alkali addn. on the saponins than in the influence of such addn. on the nature of hemolysis itself, since in expts. of this character the action of a pure saponin alone on the red blood corpuscles is not involved. On the contrary, the magnitude of the hemolytic index may be influenced by the reaction of the soln. as also by the presence of substances other than saponins in the decoction.

W. O. E.

Aspirin tablets. L. ROSENTHALER. *Pharm. Zentralhalle* **66**, 629-31(1925).—A case of substitution for the true Bayer product (including both container and label) of a competitive acetylsalicylic acid. The tablets in question were compounded with potato starch, whereas the Bayer product carries wheat starch.

W. O. E.

Tests for diethyl phthalate. HENRY LEFFMANN AND MAX TRUMPER. *Am. J. Pharm.* **97**, 507-10(1925); cf. *C. A.* **17**, 853, 1202, 2845; **19**, 152.—The procedure which calls for the addn. of a phenolic compd. and subsequent addn. of H_2SO_4 has been modified by producing sulfonic acid beforehand by addn. to 10 g. phenol 5 cc. H_2SO_4 and diluting with an equal vol. of H_2O . This soln. was used with about 15 cc. of a soln. of 2 drops of diethyl phthalate in 100 cc. alc., following the recommendation of Breithut and Apfelbaum (*C. A.* **19**, 1753) in heating for a short time at 160°. A positive reaction by production of phenolphthalein was obtained. Much stronger solns. of the ester,

such as one of the com. "rubbing alcs." gave positive results when the mixt. was simply heated in the evapg. dish. The resorcinol test as perfected by Andrew (*C. A.* 17, 2845) seems to be entirely satisfactory. Hydroquinol, pyrocatechol and pyrogallol are useless as they promptly oxidize and become dark in alk. soln. and no characteristic reactions were produced in H_2SO_4 soln. Acetone did not under any of the conditions employed give a fluorescence, but a very distinct temporary effect was obtained when small amts. of acetaldehyde were added and the higher temps. used. No effect was obtained at the low temp. prescribed by Andrews.

W. G. GAESSLER

Question of soap in dentifrices. HERMAN BRODY. *Dental Cosmos* 67, 948-52 (1925).—The sole purpose of a dentifrice is to aid in the mechanical cleansing of the teeth. Soap should be a constituent since it is a cleanser, antacid, antiseptic and emulsifier. Pure soap, used in the proper amt., does not injure the teeth, mucous membrane, or general health, and does not depress the flow of saliva. Use of an acid dentifrice does not produce a marked increase in oral alkalinity. Harsh abrasives, such as Ca phosphate, should not be present. Strongly antiseptic or alk. dentifrices are of practically no value in the prevention of dental caries. A bibliography is appended.

JOSEPH S. HEPBURN

Capillary analysis in pharmacy. GIULIO CONCI. *Boll. chim. farm.* 64, 353-7 (1925).

MARY JACOBSEN

The determination of silver and arsenic in silver arsenobenzenes. UGO CAZZANI. *Boll. chim. farm.* 64, 513-5 (1925).—The slightly modified method of Lehmann for the detn. of As in neoarsphenamine was used for the detn. of As and Ag in one sample. In an aliquot part of the oxidized soln. As was detd. iodometrically, in another Ag was titrated with 0.01 N NH_4CNS . The results are accurate for As, slightly too high for Ag. In presence of chlorides Ag is detd. as $AgCl$.

MARY JACOBSEN

The chemical assay of arsenobenzenes, with especial reference to the D. M. index. ALDO PATA. *Boll. chim. farm.* 64, 417-24 (1925); cf. *C. A.* 19, 1756.—Valeur and Launoy's results are confirmed. The reason for the inconsistent results obtained in the detn. of D. M. is probably to be sought in the too long heating with $AcOH$, which seems to cause decompn. of the arsenobenzene. Five to 6 mins. heating is sufficient for the pptn. of the latter.

MARY JACOBSEN

A clinical method for the estimation of the amount of quinine in medicinal solution. J. A. SINTON. *Indian J. Med. Research* 13, 25-8 (1925).—The quinine soln. is tested for albumin (heat coagulation). Four cc. of the soln. is dild. to 250 cc. with water. One vol. of the latter is treated with 1 volume of Tanret-Mayer reagent. (This reagent is made as follows: Add with shaking 1.35 g. mercuric perchloride in 75 cc. water to 5 g. KI in 20 cc. water and make up to 100 cc.) The opacity produced is compared with Brown's $BaSO_4$ standards or quinine standards.

FRANCES KRASNOW

An oil from Tonquin rich in cedrol. ÉTABLISSEMENTS A. CHIRIS. *Parfums de France* No. 32, 285 (Oct., 1925).—Oil obtained from the leaves of an unidentified conifer (probably a *Cunninghamia*) consisted of a light yellow semi-solid mass, contg. cryst. needles, which became completely fluid at 50° . It had d_{15} (calcd. from its soln. in xylene) 0.972, $[\alpha]_D^{18}$ $-17^\circ 10'$ (from a 51.66% soln. in xylene), acid no. 0, total alcs. as $C_{15}H_{26}O$ via acetylation in xylene soln. 30.60%, total alcs. as $C_{15}H_{26}O$ via cold formylation 73.91%, showing that the alcs. are tertiary. The cryst. portion after repeated recrystn. from alc. m. $85-6^\circ$, and has $[\alpha]_D^{20}$ $+8^\circ 33'$ (from a 17.647% soln. in xylene). A mixt. of the crystals with pure cedrol had the same m. p. With phenyl isocyanate in the cold it gives a phenylurethan m. $106-106.5^\circ$, identical with that of cedrol. The liquid portion must be strongly l-rotatory, and presumably contains cedrene.

A. P.-C.

(South) American oil of petitgrain. ÉTABLISSEMENTS A. CHIRIS. *Parfums de France* No. 32, 286-90 (Oct., 1925).—Brief description of its production and properties.

A. PAPINEAU-COUTURE

Artificial musks. L. V. DOUAU. *Rev. parfumerie* 5, 288-92 (1925).—Brief review of the com. manuf. of the more important artificial musks, $C_6(NO_2)_3Me_2CMe_3$, $C_6(NO_2)_3MeOMeCMe_3$, and $C_6(NO_2)_3Me_2COMeCMe_3$.

A. PAPINEAU-COUTURE

Formation of natural perfumes in plants: Algerian oil of geranium. ANDRÉ DUBOSC. *Parfumerie moderne* 18, 98-9, 196-200 (1925); *Bull. soc. ind. Rouen* 53, 306-21 (1925).—Review of the mechanism of the formation of perfumes in plants and of the constitution and properties of citronellol, rhodinol, geraniol and linalool.

A. P.-C.

Adulterations of saffron. G. PIERLOT. *Ann. fals.* 18, 464-8 (1925); cf. *C. A.* 10, 1490; 17, 2767.—The following forms of adulteration have been observed recently: incorporation of up to 35-40% stamens of *Crocus sativus* (normal content in pure saffron, 3-5%); petals of *Cynara cardunculus* loaded with Na glyceroborate and KNO_3 and

colored with a red dye, contained no saffron; saffron loaded (by osmosis) with up to 40-60% of borax, KNO_3 and glycerol; addn. of about 25% of invert sugar; addn. of 40% of sugar and Na_2SO_4 ; introduction of up to 50% of pollen. A. P.-C.

Note on the stability of Dakin's solution. G. W. PUCHER AND LILLIAN A. BURD. *Buffalo General Hospital Bull.* 3, 20-1 (1925).—The bleaching powder used in the prepn. of Dakin's soln. must contain at least 25% available Cl and the boric acid and NaHCO_3 employed for p_{H} adjustment must be free from organic impurities. Dakin's soln. with an initial NaOCl content of 0.500% is satisfactory for use over a period of six weeks if preserved in clean dark bottles and maintained at 10-24°. N. v. P.

Accuracy of the standardization of hypophysis preparations by means of the isolated uterus. H. SAWASAKI. *Arch. ges. Physiol.* (Pflüger's) 209, 137-69 (1925).—By the Dale-Ruidlaw method the probable error in detns. amounts to something less than 10% in 88% of the measurements, but it can be materially reduced by making sufficient detns. By the method of Kochmann the probable error is about 8%. G. H. S.

West Australian sandalwood oil. H. FINNEMORE. *Pharm. J.* 115, 168-9, 178-9; *Chemist & Druggist* 103, 178-9 (1925); P. MAY. *Ibid.* 179.—West Australian differs from the East Indian sandalwood oil in its botanical source, chem. compn. and phys. properties; hence it fails to meet the Brit. Pharm. requirements for this oil (*Bull. Imp. Inst.* 18, 163 (1920); cf. *C. A.* 17, 2472). However, in discussion, P. May found no chem. or phys. differences in recent, authentic Australian oils; agreement exists even in optical rotation. He recommends an impartial pharmacol. and clinical examn. of the Australian oil (cf. *C. A.* 13, 2415, 2730; 19, 418, 3349). S. WALDBOTT

True and false santonicas. T. E. WALLIS AND ELLINOR J. MOWAT. *Pharm. J.* 115, 149-56; *Chemist & Druggist* 103, 182-5 (1925).—A detailed botanical description, with line drawings, is given of many species of *Artemisia*, section *Seriphidium*, enabling the formulation of botanical characteristics by which the flower heads of genuine santonica of commerce may be identified with certainty. The botanical source of true com. wormseed is *Artemisia cina* (Berg) Willkomm, differing from *A. maritima*, var. *α -Stechmanniana*, Besser, of the Brit. Pharm., (Flückiger and Hanbury) and from *A. pauciflora*, Weber (*A. lercheana*, Karel. et Kiril.) of the U. S. P. (Bentley and Trimen). Com. specimens of santonica devoid of santonin (cf. *C. A.* 16, 4296) can all be distinguished from the true drug botanically. The plant cultivated in Holland (*C. A.* 18, 1364) is not *A. cina*, Berg, but is a distinct species differing from all those examd. S. WALDBOTT

The structure of Coscinium. G. R. A. SHORT. *Pharm. J.* 115, 156-62; *Chemist & Druggist* 103, 185-6 (1925).—A detailed histological and general description of the stem of *Coscinium fenestratum*, Colebrooke, native of Ceylon, (false calumba root) is given, with drawings and 11 references. Several com. samples of "*Berberis aristata*" consisted entirely of *Coscinium* stem. Definite histological differences exist also between the stems of *C. fenestratum* and *C. wallichianum*, Miers. S. WALDBOTT

Sulfur content of arspenamine (CHRISTIANSEN, *et al.*) 10. Assaying HgI_2 , HgCl_2 , and some other Hg compounds (ELLMAN) 7.

Organic antimony compounds for pharmaceutical use. H. HAHN. U. S. 1,561,535, Nov. 17. In making alkali metal salts of complex Sb compds. of mercapto-carboxylic acids, the mercapto-carboxylic acid, e. g., thiosalicylic acid, or thioglycolic acid, is treated with Sb_2O_3 , $\text{Sb}(\text{OH})_3$ or other O deriv. of tervalent Sb, and the resulting product is neutralized with Na_2CO_3 or other suitable alkali metal compd.

Synthetic drugs. F. LEHNHOFF-WYLD. *Brit.* 232,612, April 17, 1924. Metallic derivs. of 3,3'-diamino-4,4'-dihydroxyarsenobenzene-*N*-methylenesulfonic acid are prepd. by reaction of a sol. metallic salt such as ZnCl_2 or compds. of Mg, Cd, Cu or Ag with 3,3'-diamino-4,4'-dihydroxyarsenobenzene before or after its conversion into the methylenesulfonate.

Medicines. INSTITUT SERO-THERAPIQUE ET VACCINAL SUISSE. *Brit.* 232,906, April 28, 1924. Substances for use in dentistry or medicinal, antiseptic or cauterizing substances (e. g., As_2O_3 , Co oxide or arsenites formed within the jellies by reaction between As_2O_3 and oxides, hydroxides or salts of alk. earths or noble or heavy metals) are suspended uniformly in gelatin, agar agar, cellulose or other gelatinous substance which is caused to set, dried and formed into tablets, balls, etc., contg. a known amt. of the active ingredient.

Medicinal irritant from the Rhus plant. P. MASUCCI. U. S. 1,559,340, Oct. 27. A soln. is formed comprising a fixed vegetable oil such as cottonseed or olive oil and the

irritant or vesicant principle of the *Rhus*. This compn. is adapted for use as a therapeutic agent.

Deodorant mixture. A. G. SMITH. U. S. 1,558,405, Oct. 20. A mixt. adapted for use on the skin comprises NaHCO_3 50, Zn stearate 10, CaSO_4 20 and talc 20%.

Massage cream or paste. C. M. GEARHART. U. S. 1,558,160, Oct. 20. S and an astringent such as alum are used with glycerol, starch and H_2O .

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Synthesis of ammonia by the Casale process. J. DUBOURG. *Technique moderne* 17, 714-6(1925).—Brief description of the process. A. PAPINEAU-COUTURE

The industrial uses of zirconium ores. M. F. BERTRAND. *Rev. universelle mines* [7], 7, 218-34(1925).—The occurrence, properties and analysis of Zr ores, the prepn., phys. and chem. properties and uses of Zr, the value and use of ZrO_2 and Zr silicate as refractories, the manuf. of porcelain and enamels with ZrO_2 and various other uses of ZrO_2 are described. C. C. DAVIS

Pyrites containing selenium. I. WOLKOFF. *Bumashnaja Promuschlennostj* (Russia), No. 2 (1925); *Zellstoff u. Papier* 5, 355-6(1925).—The removal of Se from SO_2 , resulting from the burning of pyrites, by suitable washing operations is discussed. Se acts catalytically to form SO_3 . Pyrites from the Ural mountain region contain 20 g. Se per ton. J. L. PARSONS

The stability of solid calcium hypochlorite. H. H. KING. *Indian J. Med. Research* 13, 191-4(1925).—Ca hypochlorite is stable if dry and air-tight. F. K.

The salt industry of Poland. P. H. SERAPHIM. *Kali* 19, 354-6(1925).

WM. B. PLUMMER

The cast basalt industry. ANON. *Le Génie civil* 87, 57(1925).—The cast material has great physical strength and chemical resistance. It is used for insulators and for chemical apparatus. JACK J. HINMAN, Jr.

Removing water from oils and solvents. C. F. GREEN. *Textile Colorist* 47, 644(1925).— H_2O may be removed from oils and solvents before lab. distn. by mixing them with very finely powd. gum tragacanth. This absorbs the H_2O , swells and settles on standing. CHAS. E. MULLIN

Ebony and its substitutes. E. J. FISCHER. *Kunststoffe* 14, 113-6, 164-5, 181-3(1924).—The general properties of ebony wood are discussed. Substitutes consist of various woods dyed to match the color of ebony; artificial products consisting largely of cellulose fibers and a binder, such as albumin, casein or blood; products free of cellulose contg. glue, glycerol, waxes or resins, casein or rubber; and cellulose esters or artificial plastics (phenol resins, etc.). A list of 24 patents relating to the manuf. of these substitutes is given. C. J. WEST

Manufacture of artificial cork. OTTO LINCKE. *Kunststoffe* 14, 116(1924).—Very general discussion of the manuf. of "Subertit," made from cork waste and a suitable binder. C. J. WEST

New impregnating and binding agents. M. BOTTLER. *Kunststoffe* 15, 4-6(1925).—Discussion of various trade products. C. J. WEST

Advances in the field of adhesives and binding agents. MAX BOTTLER. *Kunststoffe* 15, 89-91, 114-7(1925).—Patent review. C. J. WEST

Artificial products from blood. K. J. BREUER. *Kunststoffe* 15, 1-2(1925).—The blood is dried by spraying into a stream of warm air or heated with superheated steam, pressed and finally dried. 100 l. blood gives 14 kg. dry material, deep black in color. This is finely ground and then pressed or molded into the desired shapes. C. J. W.

Animal size. E. O. RASSER. *Kunststoffe* 15, 23-4, 38-41, 55-6(1925).—Review of methods of prepn. and tests. C. J. WEST

Sealing waxes. LEIT. *Kunststoffe* 15, 109-11(1925).—In part a review of Andes' book on this subject; in part, of recent German patents. C. J. WEST

Old and new about polishes and polishing varnishes. FRITZ ZIMMER. *Farben-Ztg.* 31, 390-400(1925).—Review. F. A. WERTZ

Organic glasses. J. FRERES. *Rev. prod. chim.* 28, 113; *Kunststoffe* 15, 92-4(1925).—Discussion of the history of the condensation of $\text{CO}(\text{NH}_2)_2$ and HCHO . C. J. WEST

Recent advances in the preparation of plastic masses. S. HALEN. *Kunststoffe* 15, 19-23, 70-82, 134-5(1925).—Patent review. C. J. WEST

Modern plastic masses. A. HUTIN. *Rev. gen. mat.-plastiques* 1, 57-63, 105-11,

163-7(1925); *Kunststoffe* 15, 116-7, 196-9(1925).—A large number of the trade names of various artificial plastics are given; the method of prepn. is indicated in most instances; in some cases patent references are given.

C. J. WEST
Condensation of formaldehyde with phenols. H. BARTHÉLÉMY. *Kunststoffe* 15, 150-1(1925).—See C. A. 19, 2552.

The manufacture of chewing gum as a problem in dispersion. RUDOLF DITMAR. *Gummi-Ztg.* 40, 156-8(1925).—A review of various patented processes, with special reference to the Pratt process of dispersing rubber in H_2O (cf. Brit. pat. 233,370).

C. C. DAVIS
Impregnation of waterproof materials. KARL MICKSCH. *Kunststoffe* 14, 133-4 (1924).—Various methods are discussed, alum and lead acetate, Cu salts, linseed oil, etc., being used.
C. J. WEST

The classification of common salt by its iodine content (RÓZSA) 11G. The gasification of molasses residues and the recovery of potash, NaCN and $(NH_4)_2SO_4$ (MÜHLERT) 2B. Effect of X-rays on the Pt catalyst in the contact H_2SO_4 reaction (CLARK, *et al.*) 2.

LANGTON, H. M.: **Blacks and Pitches.** Ernest Benn, Ltd. 178 pp. 15s., by post 15s. 6d. Reviewed in *Munic. Eng.* 76, 116; *Chemistry and Industry* 44, 999 (1925).

Sulfuric acid. H. KLENCKE. U. S. 1,561,985, Nov. 17. Gases contg. SO_2 are brought into contact with nitrosyl sulfuric acid of a sp. gr. of about 58° Bé. and of the highest possible concn. with respect to N-O compds. and the resulting gas mixt. is then brought into contact with nitrosyl sulfuric acid of a sp. gr. of about 66° Bé. and of about the highest concn. attainable in N-O compds.

Sulfuric acid. C. B. CLARK. Can. 251,618, Oct. 13, 1925. In the contact process of producing H_2SO_4 , SO_2 gases of a temp. above the one used for the contact reaction are produced and these are cooled before the first contact stage by causing them to give up heat to the gases which are on their way from the absorption stage to the next contact stage after such gases have abstracted heat on the way from the first contact stage to the absorption stage. App. is also specified.

Purifying waste waters containing sulfuric acid. J. A. NEWLANDS. U. S. 1,557,188, Oct. 13. Waste waters from pickling brass or other waste waters contg. H_2SO_4 are freed from Cu and H_2SO_4 (e. g., by use of Zn) or other impurities which would impair the quality of the product to be produced or contaminate streams and are then treated with Zn to form $ZnSO_4$. Ba sulfides are then added and the pptd. ZnS and $BaSO_4$ are sepd. from the liquor for use as a pigment.

Hydrocyanic acid. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT (VORM. ROESSLER) and O. LIEBKNECHT. Brit. 232,834, Aug. 1, 1924. HCN is sepd. from gaseous mixts. by use of absorbents such as activated charcoal or silica gel, in the presence of H_2O , steam, or acids or other liquids which themselves are capable of absorbing HCN.

p-Hydroxy-m-nitrophenylarsenious acid. IWAN OSTROMISLENSKY. Can. 255,009, Oct. 27, 1925. Arsanilic acid is diazotized in the presence of water at 70°, the diazotized product is nitrated at a temp. below the b. p. of the mixt., an alkali is added and the alk salt of p-hydroxy-m-nitrophenylarsenious acid is recovered.

Apparatus for ammonia synthesis. I. W. CEDERBERG. Can. 250,080, May 26, 1925.

Combining alkaline earth metals with other refractory metals. H. BOVING. U. S. 1,562,202, Nov. 17. In combining an alk. earth metal, e. g., Ba, with a refractory metal of higher volatilizing temp., such as Ni, W or Pt, the refractory metal is formed into thin strips, a spongy mass, filaments or other configuration having a large ratio of surface to vol. and it is then exposed to vapor of the alk. earth metal at a temp. lower than the m. p. of the combined metals.

Arsenical salts. S. J. LLOYD and A. M. KENNEDY. Can. 253,583, Sept. 15, 1925. As_2O_3 is dissolved in NaOH, the arsenite is converted into arsenate by electrolytic oxidation, and to the soln. is added a soln. or suspension of a salt of a base producing an insol. arsenate which is sepd. and the soln. reused in the process.

Drying calcium hypochlorite. CHEMISCHE FABRIK GRIESHEIM-ELEKTRON. Brit. 232,560, April 15, 1924. $Ca(OCl)_2$ or basic hypochlorite is partially dried by heating and then mixed with CaO to combine with residual H_2O .

Zinc oxide. A. FORGEUR and L. GRANGE. Brit. 232,610, April 16, 1924. Roasted blende or other crude material contg. ZnO , which may be first treated with H_2O to remove sol. sulfates, is treated with NH_4Cl soln. in an autoclave to dissolve the Zn

The soln. is treated with metallic Zn to remove Cu and is then poured into H_2O to ppt. $Zn(OH)_2$. NH_3 liberated in the autoclave is led to the hydrolysis vessel and the NH_4Cl soln. is concd. and used repeatedly.

Iron oxide and sulfur trioxide from ferrous sulfate. AUSTRAL PIGMENTS, LTD. Brit. 232,581, April 16, 1924. Hydrated $FeSO_4$ crystals are directly heated by a gas flame or otherwise so as to liberate the H_2O of crystn. at a temp. above 64° to avoid caking. Monohydrated sulfate thus produced is ground, oxidized with air to form a basic ferric sulfate and then calcined in a roasting furnace to produce Fe_2O_3 and SO_3 . Details of heating app., etc., are described.

Recovery of hydrated oxides of iron and calcium sulfate. J. B. DUFAUR. Can. 254,503, Oct. 13, 1925. $CaCl_2$ is added to Fe sulfate solus., the $CaSO_4$ pptd. is removed and $CaCO_3$ is added to the soln. which is agitated with air under pressure to ppt. Fe in the ferric state.

Titanium oxide. METAL AND THERMIT CORPORATION. Brit. 232,680, Jan. 23, 1924. A black form of TiO_2 which is a conductor of heat and electricity is obtained by heating TiO_2 or rutile to 800 – 1000° in a covered crucible in a gas- or oil-fired furnace or in H . The material may be first molded into electrodes, conductors or containers for elec. or chem. purposes.

Titanium oxide. S. J. LUBOWSKY. Can. 253,964, Sept. 22, 1925. An electrically and thermally conductive oxide of Ti is formed by heating TiO_2 in a non-oxidizing atm. at 800 – 1000° .

Hydrogen. J. ROCHET. Can. 254,162, Sept. 29, 1925. In the production of H by the reduction of water vapor with metallic Fe and then reducing the FeO formed with a reducing gas, the reaction mass is maintained at a uniform reacting temp. by arranging the mass in small thicknesses in narrow chambers which are heated by circulating a double current of gas along their walls.

Nitrogen and hydrogen mixtures. J. ROCHET. Can. 254,163, Sept. 29, 1925. A mixt. of CO , H and hydrocarbon gases is burned in an excess of air and the products of combustion are subjected to the action of H in excess at a temp. suitable for the combination of the H and of the free O contained in the gases, then absorbing the CO_2 by means of NH_3 soln.

Sulfur burner. H. F. MERRIAM. Can. 254,659, Oct. 13, 1925.

Moldable mixture of sulfur and lime. C. E. HITE. U. S. 1,551,307, Aug. 25. A powd. mixt. comprising S 1 and hydrated lime 3 parts is adapted, on addn. of H_2O , for use as a mortar, plaster, etc.

Casein. A. MESSMER. U. S. 1,557,181, Oct. 13. Curd, sepd. from whey, is discharged from its container in a stream into which a stream of cold H_2O is directed. H_2O is drained from the curd and the latter is centrifuged and washed.

Modified casein. H. V. DUNHAM. U. S. 1,551,471, Aug. 25. H_2O and an excess of caustic alkali are added to casein and sufficiently heated to form NH_3 . Excess $NaOH$ is neutralized with NH_4Cl by heating. The product thus formed is adapted for sizing paper, leather, cloth, etc.

Dental cement. P. W. KRUGER. U. S. 1,556,696, Oct. 13. Guaiacol is used as a setting agent with a powder contg. kaolin and MgO or with other dental cement-forming ingredients.

Bleaching solutions. D. A. PRITCHARD. Can. 254,155, Sept. 29, 1925. A predetd. quantity of liquid Cl from a storage tank is heated to form gas, the pressure exerted by the gas is used to feed liquid Cl into a chlorinated chamber where it is thoroughly mixed with a base.

Plastic molding composition. R. W. SEABURY. U. S. 1,561,525, Nov. 17. A compn. for manuf. of battery jars or other molded articles comprises a phenolic condensation product, and a filler, e. g., SiO_2 and wood-flour, in intimate mixt. with particles contg. a vulcanizable rubber compn. and a filler.

Colored plastic composition comprising phenolic formaldehyde condensation products or similar substances. C. T. FULLER. U. S. 1,560,346, Nov. 3. Cements (for uniting glass to metals) or other products are formed from material such as "bakelite" or similar compns. which are capable of being hardened or cured without change in color by heating to a crit. temp., admixed with malachite green or other coloring material which changes color or fades out permanently only when heated to the temp. of curing or hardening, e. g., at 150 – 220° .

Composition of fibrous material and phenol resin. L. V. REDMAN and H. C. BERTHAM. U. S. 1,551,428, Aug. 25. Cotton, paper pulp or other fibrous material is compounded with a non-reactive phenol resin and a hardening agent such as CH_2O .

or $(\text{CH}_2)_6\text{N}_4$, with or without furfural, in the presence of H_2O contg. PhOH or other free phenolic substance. The product is adapted for making laminated sheets.

Fibrous material impregnated with phenolic condensation products. K. BROWN. U. S. 1,559,846, Nov. 3. Fibrous material such as laminated paper or cloth sheets for making gears, etc., is impregnated in its inner portion with substances such as PhOH and CH_2O which are capable of reacting to produce a H_2O -resistant phenolic condensation product; less of the CH_2O or other hardening reagent is used than would be required to produce a condensation product of max. hardness and infusibility. The outer portion of the fibrous material is similarly impregnated, with the use, however, of a larger proportion of the hardening reagent and the materials are then heated to effect reaction and different degrees of condensation and hardening in different portions of the material.

Impregnating strings of fibrous material with phenolic condensation product. F. S. SMITH. U. S. 1,557,730, Oct. 20. A string formed of jute, cotton or other similar org. material is impregnated with "Bakelite A" dissolved in a mixt. of EtOH or MeOH and C_6H_6 or other solvent and is then subjected to the action of a high-tension elec. current for removing the solvent and thereafter converting the "bakelite A" into the "B" form.

Condensation products. K. RIPPER. Can. 254,238, Sept. 29, 1925. A mixt. of urea and formaldehyde is heated, the product is preferably concd. by evapn. and basic substances and salt-like electrolytes are added just before the final insol. products are formed.

Sealing composition. S. FREEDMAN. U. S. 1,558,008, Oct. 20. A sealing liquid for compressed air containers is formed of glue, sawdust, Na_2CO_3 , rubber shavings and resin, cooked together in H_2O .

Acidproof composition. CONSOLIDATED MINING AND SMELTING CO. OF CANADA, LTD., F. S. WILLIS and B. A. STIMMEL. Brit. 232,742, March 12, 1924. An acidproof mixt. for use as a lining, etc., is prepd. by mixing sand 70-60 with melted S 30-40% and heating the mixt. to about 150° , after which it may be cast or used as a plaster.

Friction material for brake linings, etc. I. J. NOVAK. U. S. 1,561,740, Nov. 17. Mech. features of molding and heat-treating products such as those formed from asbestos, phenolic resin and gum sandarac. Cf. C. A. 20, 98.

Friction-resisting material for facing or lining clutches or brakes, etc. P. A. ANDREWS. U. S. 1,559,146, Oct. 27. Mech. features of forming molded products from materials such as reinforced mixts. of asbestos and cement.

Revivifying fuller's earth. F. W. HALL. U. S. 1,558,162, Oct. 20. Decolorizing clay which has been used for oil refining is treated with a solvent comprising acetone and gasoline. U. S. 1,558,163 specifies the use of a mixt. of acetone and C_6H_6 .

"Dustless" crayons. J. A. HAUFF. U. S. 1,561,075, Nov. 10. Hydrated Al silicate and magnesia are mixed with a binder such as gum arabic and moistened to produce a putty-like mixt. This is allowed to season, molded and subjected to spontaneous air drying. The product is suitable both for use dry as a crayon and for use with H_2O as a water color and also may be used in plastic form as a painting medium. Kaolin, steatite and talc may be used.

Purifying graphite. E. J. E. DUMOND. Brit. 232,936, April 23, 1924. To remove siliceous and other impurities, crushed crude graphite is triturated in moist condition, sieved in the presence of H_2O and subjected to a flotation sepn. Further purification may be effected by heating the material in a kiln with Na_2CO_3 , treating with dil. HCl , washing and further sieving.

Lithographic printing plate. W. GRASS. U. S. 1,562,324, Nov. 17. Exposed portions of metal plates such as those of Zn are subjected to an etching bath contg. "a neutralized acid," e. g., FeCl_3 soln. treated with NaHCO_3 and also contg. HNO_3 and HCl or other etching acid.

Composition for preventing obscuration of glass panes by moisture. R. V. RIDGELY. U. S. 1,556,714, Oct. 13. A mixt. of soap, glycerol, waterglass and H_2O .

"Antitarnish" composition. T. H. LASHAR. U. S. 1,561,650, Nov. 17. A compn. adapted for use by jewelers on silverware, etc., to prevent tarnishing comprises a soln. of Pb acetate or other metal salt capable of absorbing H_2S , in a hygroscopic non-volatile solvent such as glycerol.

Composition for cleaning and polishing silverware, etc. E. M. BURKET. U. S. 1,560,659, Nov. 10. A mixt. of rouge, CaCO_3 , floated pumice, H_2O and whiting.

H. F. S.

The renumbering of Seger cones. KNUTH, MICHR AND STEPHAN. *Tonind. Ztg.* **49**, 1234-6(1925).—The present method of numbering Seger cones is too complex because it requires a table to convert the cone numbers into temps. It is suggested that the cones be numbered so as to correspond to the temp. at which they soften, as below:

Cone no.	Temp., °C.	New cone no.	Cone no.	Temp., °C.	New cone no.	Cone no.	Temp., °C.	New cone no.
022	600	60	1a	1100	110	28	1630	163
021	650	65	2a	1120	112	29	1650	165
020	670	67	3a	1140	114	30	1670	167
019	690	68	4a	1160	116	31	1690	168
018	710	71	5a	1180	118	32	1710	169
017	730	73	6a	1200	120	33	1730	173
016	750	75	7	1230	123	34	1750	175
015a	790	79	8	1250	125	35	1770	177
014a	815	81	9	1280	128	36	1790	179
013a	835	83	10	1300	130	37	1825	182
012a	855	85	11	1320	132	38	1850	185
011a	880	88	12	1350	135	39	1880	188
010a	900	90	13	1380	138	40	1920	192
09a	920	92	14	1410	141	41	1960	196
08a	940	94	15	1435	143	42	2000	200
07a	960	96	16	1460	146			
06a	980	98	17	1480	148			
05a	1000	100	18	1500	150			
04a	1020	102	19	1520	152			
03a	1040	104	20	1530	153			
02a	1060	106	26	1580	158			
01a	1080	108	27	1610	161			

R. RIEKE in answer to this article opposes this change. The numbering has been the standard for the past 40 years and the change would necessitate changing all references for the past to the new numbers when referring to them. It would also cause considerable confusion among the practical men who have learned to use the cones according to their old numbers.

The Swedish feldspar industry. A. S. W. ODELBURG. *Trans. Ceram. Soc. (Eng.)* **24**, 275-7(1924-25).

H. F. S.

Observations on the elimination of carbonaceous matter from fireclay bricks. L. S. THEOBALD AND A. T. GREEN. *Trans. Ceram. Soc. (Eng.)* **24**, 159-69(1924-25).—The material used was Stourbridge fireclay, as this seemed to show the elimination of the carbonaceous matter to the greatest advantage. Under the particular conditions of the heat treatment, no change is apparent in the test specimen at temps. below 500° , but at 600° oxidation has, undoubtedly, commenced. With full-sized bricks drawn from actual burns, the cores become distinctly darker and blacker as the time at 600° is increased, indicating that as heating continues further changes are taking place in the carbonaceous matter in the center of the piece. As soon as the temp. approaches 650° , a white ring, which develops into a yellow area follows the removal of the carbonaceous matter. Above 600° some chem. action takes place in a deficiency of air in the

interior of the piece, which is manifested as a yellowish area replacing the C. On heating to 750°, there is a darkening in the shade of the interior as if a diffusion of C had taken place. Reduction of the Fe to the ferrous state may also contribute to this change. The black cores at this temp. are definitely replaced by persistent yellow areas and a more prolonged soaking at 750° would not remove them. H. F. S.

The action of carbon monoxide on fire brick. GILARD. *Rev. universelle des mines de Liège*, December 1, 1923; *Le Genie civil* **84**, 457-8(1924).—The CO penetrates the fire brick and if the brick contains Fe_2O_3 it reacts setting free C. Disintegration results. American work is noted. JACK J. HINMAN, JR.

The electrical conductivity of magnesia refractories at high temperatures. J. T. BURT-GERRANS AND R. S. KERR. *Trans. Roy. Soc. Can.* **19**, 27(1925).—The sp. cond. of new magnesia bricks increases from 2×10^{-6} reciprocal ohms per cc. at 870° to 5×10^{-6} at 1020° then falls to 2×10^{-6} again at 1080° and finally increases with the temp. to 0.27 reciprocal ohms at 1550°. Bricks after heating above 1400° and then cooling showed decreased cond. between 1200° and 1300° but behaved as new bricks at higher temps. J. W. SHIPLEY

Laboratory production of pure magnesia ware. R. F. MEHL, J. L. WHITTEN AND D. P. SMITH. *Ind. Eng. Chem.* **17**, 1171-2(1925).—Pure MgO crucibles and tubes are made by (1) heating pure MgO for 1 hr. at 1800°, (2) mixing with shellac (12 g. orange shellac in 80 cc. EtOH or MeOH, mixed with 120 g. of the previously heated MgO), (3) pressing into mold, (4) drying at room temp. for 1 hr., (5) drying at 150° for 2 hrs. or more, (6) firing at 1800° for 1 hr. The resulting ware is excellent. C. H. KERR

Apparatus for drying "ceramic and chemical products" (Brit. pat. 232,851) 1. Refractory oxides and alloys (Brit. pat. 232,549) 9.

Polishing and glazing glassware. A. B. KNIGHT. U. S. 1,562,341, Nov. 17. The ware is subjected to the action of a polishing burner, and then, after lowering its temp., to the action of a glazing burner. U. S. 1,562,342 relates to a glass-working burner construction.

"Plastic fire brick." W. A. L. SCHAEFER. U. S. 1,561,571, Nov. 17. Fire bricks are formed of a clay rich in Al_2O_3 (apportioned into raw and calcined portions in the ratio of 9:2 parts, mixed together) mixed with ground burner fire brick in the proportion of 11 and 18 parts, resp.

Chamotte bricks. S. E. SIEURIN. U. S. 1,561,492, Nov. 17. There is added to the main mass from which the bricks are formed a binder consisting of a mixt. of finely divided SiO_2 and fireclay, the mixt. being so proportioned that after heating to glowing it contains 73-90% SiO_2 .

Bricks, pottery, etc. V. M. GOLDSCHMIDT and J. C. W. VAN KROGH. Brit 232,943, April 25, 1924. In the manuf. of burnt or sintered clay products, the base material is mixed, before burning, with a substance which is richer in Fe, in such quantity as to effect an increase in the % of FeO compds in the final product of 3-15%. About 1% of borax also may be added. A rapid burning of the material produces a relatively porous product and a slower burning a product of greater solidity.

Refractory composition. W. A. FARISH. U. S. 1,561,641, Nov. 17. A non-crystd. refractory compn. adapted for making crucibles, retorts, pyrometer tubes, etc. comprises a refractory elec. furnace product such as SiC_2 , Al_2O_3 or SiO_2 , 65, a carbonizing binder, e. g., tar 32, and borax 3%.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

A native national wealth, the cement of Vassy. G. BIDAUT DE L'ISLE. *La nature* **53**, ii, 182-7(1925).—An illustrated description of the geological, phys. and chem. characteristics of the deposit of argillaceous limestone at Vassy. It produces an excellent hydraulic cement, forming with H_2O a double Ca-Al silicate of unusual hardness. It contains no Mg and gives a product which in strength and adherence is in a few days the equal of most hydraulic limes and portland cements after several yrs. Like *ciment fondu* it is not decompd. by sea or selenitic waters and does not slowly expand under such conditions. It is of extreme value where *rapid setting* is necessary, such as emergency work, particularly under H_2O . C. C. DAVIS

Close water control important in alumina cement concrete. P. H. BATES. *Eng.*

News-Rec. 95, 462-3(1925).—Expts. showed that marked decrease in strength accompanies use of excess water with high-alumina cement, as little as 0.5% (of wt. of dry mix) causing distinct reduction. Grading of aggregate, by influencing amt. of water required to secure workability, is also a factor. R. E. THOMPSON

The properties of aluminate cement. R. L. MORRISON. *Cont. Rec.* 39, 417-8 (1925).—Tests of properties of American aluminate cement (Atlas Lumnite Cement Co.) indicated that max. strength is reached in 3-5 days, strength of 1:2:4 aluminate cement concrete at 5 days being almost twice that of the best 1:2:4 portland cement concrete at 29 days. At 29 days a 1:4:8 aluminate cement concrete has approx. the same strength as 1:3:6 portland cement concrete, while 1:3:6 aluminate is approx. as strong as 1:2:4 portland. In practically all the cases, the strength of aluminate concrete was inversely proportional to the amt. of water used. The amt. of water required to produce a given slump with aluminate cement was practically the same as with portland cement. In almost every case cylinders cured in dry air were stronger than those cured in moist air, the av. difference in strength being 7%. An av. of 209 lbs. per sq. in. was required to break at the end of 24 hrs. 6 cylinders made by replacing in molds half-briquets of portland cement and filling the rest of the space with aluminate cement mortar. Results of setting time tests made upon mixts. of aluminate and portland cements showed that flash set does not occur unless the proportion of portland cement falls between 33 and 90%. R. E. T.

The influence of the quantity of water in the mixture on the heat of setting of aluminous cements. J. BERTET. *Genie civil* 84, 542-4(1925).—Two distinct reactions are indicated. J. J. HINMAN, JR.

Slag in wet process cement manufacture. SOZO KANO. *Concrete* (Mill Section) 27, 93-7(1925).—Data are given on setting time of clay-limestone and slag-limestone slurries. Because of hydraulic properties of granulated slag, continuous agitation of slag-limestone slurry is necessary. RAYMOND WILSON

Method for testing fine aggregate. G. W. HUTCHINSON. *Eng. News Rec.* 95, 395(1925).—As standard test methods are of questionable economic value, an attempt was made to devise a method more consistent with the use of fine aggregate under field conditions. The test adopted consists in proportioning materials as follows—dry vol.: cement 23%, fine aggregate 46%, coarse aggregate 76%, with a standard consistency analogous to that required in field concrete. The specimens, 3 × 6 in. cylinders, were stored in a moist closet until compared with similar specimens made with standard Ottawa sand. Prepared coarse aggregate (Mascot Chats), grade $\frac{3}{8}$ to $\frac{3}{4}$ in., was employed. R. E. THOMPSON

Preservation of wood. SEDLACZEK. *Kunststoffe* 14, 49-52, 103-5, 134-6(1924).—Discussion of patented processes. C. J. WEST

Experimental study on the transmission of heat by some building materials made at the University of Lausanne. DUMAS. *Bul. technique de la Suisse romande* Nov. 10 and 24, 1923; *Genie civil* 84, 43-4(1925).—Expts. made with walls electrically heated from within showed that a considerable role is played by moisture. Porous materials when dry give much better insulation than more dense substances, but a wet porous wall conducts heat more strongly than a less porous wall does when dry. JACK J. HINMAN, JR.

The effect on the principal building materials of carbonated and iron-bearing mineral waters. P. LIEGEAIS. *Ann. soc. geol. Belg.* 48B, 30-2(1925).—Marble is diminished $\frac{1}{8}$ the original weight after 10 months immersion. Siliceous-aluminous substances are not appreciably affected, although artificial substances of like character, such as brick, are easily corroded. A mixt. of 50% sand and 50% port. cement is completely disintegrated 4 hours after setting. Siliceous substances such as quartzite, and sandstone, and eruptive rocks with a siliceous base are not affected. O. F. P.

Cement production (Brit. pat. 232,930) 9.

Deterioration of Structures in Sea Water. Fifth (Interim) Report of the Com-

mittee of the Institution of Civil Engineers. H. M. Stationery Office. 65 pp. 3s. 6d. by post 3s. 8d. Reviewed in *Munic. Eng.* 76, 285(1925).

Portland cement. A. G. CROLL. U. S. 1,562,207, Nov. 17. A cement of high strength is produced by burning the ingredients at a clinkering temp., quenching the clinker at white heat, and grinding.

Cement. E. C. ECKEL. Can. 253,811, Sep. 22, 1925. A cement contains calcareous material, TiO_2 , FeO and Al_2O_3 . Cf. C. A. 19, 3579.

Cements. L. G. PATROUILLEAU AND ALUMINE ET DERIVES. Brit. 232,898, Dec. 19, 1924. In making aluminous cements the raw materials are treated with SO_2 or a substance capable of supplying SO_2 in order to prevent formation of silicates. H_2S , S , sulfides such as Fe pyrites, sulfites, hyposulfites, or sulfates such as those of Fe , Al or Ca may be used.

Articles of concrete impregnated with sulfur. R. F. BACON, W. H. KOBBE and P. H. BASCOM. U. S. 1,561,767, Nov. 17. The interstices of building blocks, conduits or other articles formed of concrete are filled with S , e. g., by immersion in molten S at 125° , so as to produce a material having at least 10 times the tensile strength of the concrete itself.

Artificial stone. H. S. LUKENS. U. S. 1,561,473, Nov. 17. A wet mixt. is formed from soapstone in small fragments or other aggregate (other than ores of metals), with a binder mainly consisting of MgO and sufficient H_2O to confer plasticity, and, while wet, the mixt. is carbonated to convert the MgO into MgCO_3 .

Preserving stone. A. P. LAURIE. U. S. 1,561,988, Nov. 17. Sandstone or other stone is soaked in a soln. of an undecomposed silicic ester, e. g., a soln. formed from SiCl_4 and HCl in alc. and CaH_2 or other volatile solvent (the HCl being volatilized) and the moisture of the air is allowed to hydrolyze the soln. so that a continuous film of hydrated silica is formed in the stone and holds it together.

Road construction. R. W. COBURN. U. S. 1,561,139, Nov. 10. Crushed stone and dry mortar are deposited upon a base and an overlying layer of bituminous material is then applied before the mortar has set, so that good bonding is effected.

Roofing felt of asbestos and other fibrous material in united layers. F. C. OVERBURY. U. S. 1,558,495, Oct. 27.

Mixing asphalt with fibrous and abrasive materials. A. R. LUKENS. U. S. 1,556,703, Oct. 13. Sep. batches of asphalt or the like are mixed, resp., with fibrous and abrasive materials such as paper waste and kieselguhr and the 2 batches are then mixed to obtain a product for making roofing or other purposes. The sep. mixing minimizes the action of the abrasive on the fiber.

Floor covering. C. M. TAYLOR. U. S. 1,562,382, Nov. 17. The tensile strength of a dry felt flooring material is increased by satg. it with a mixt. of a cellulose ester and a vegetable drying oil, e. g., a mixt. of nitrocellulose, linseed oil and solvent. U. S. 1,562,383 specifies satg. a felt base with asphalt or similar material and coating it with a compn. formed from nitrocellulose 12, a solvent such as "acetone oil" and naphtha 88, resin 12 and linseed oil or a similar vegetable oil, 12 parts.

Floor covering. C. M. TAYLOR. U. S. 1,562,384, Nov. 17. A floor covering is prepd. as described in U. S. pat. 1,562,383 (cf. above) and then, after drying, is given a coating of paint. U. S. 1,562,385 specifies applying, over the paint coating, an additional coat of compn. formed of nitrocellulose 10, a solvent such as "acetone oil" and C_6H_6 90 and linseed oil or other softening agent 10 parts. U. S. 1,562,386 specifies impregnating felt or a similar porous base with asphalt or the like and then successively coating it with paint and with a film of pyroxylin or other cellulose ester. U. S. 1,562,387 specifies satg. felt with a nitrocellulose compn. and then coating it with a film of pyroxylin or similar material on both sides.

Pulverized fuel and low temperature carbonization in relation to the mining industries. DAVID BROWNLIE. *Combustion* 13, 101-4(1925). J. F. BYRNE

Boiler-furnace design for pulverized fuel. J. G. COUTANT. *Combustion* 13, 278-9 (1925).—Changes in boiler furnace design to meet the conditions imposed by the use of pulverized fuel are discussed. J. F. BYRNE

Furnace heating. VIII. R. J. SARJANT. *Fuel in Science & Practice* 4, 383-95 (1925); cf. C. A. 19, 3362.—An illustrated review and discussion of the influence of the furnace atm. on the materials heated and the use of heat-resistant steels, the phys. and chem. properties of refractory materials and the influence of repeated heating and cooling, the proper selection of refractories, melting furnaces, open-hearth furnaces, hearth area, ports, regenerators, valves, the general construction of a furnace and the heat balance. C. C. DAVIS

Present status of the facts and theories of detonation. G. L. CLARK AND W. C. THREE. *Ind. Eng. Chem.* 17, 1219-26(1925).—A review with an extensive bibliography (61 references), certain of the more significant data covering the effect of various factors on gaseous detonation being tabulated. The various theories which have been advanced are discussed briefly and further suggested research is outlined. WM. B. PLUMMER

Faulty oil causes carbon? J. W. ORELUP AND O. I. LEE. *Petr. Age* 16, No. 2, 50-2(1925); cf. C. A. 19, 2398.—The reaction producing cylinder carbon, which consists of highly condensed hydrocarbons of a bituminous nature, is still an open question but probably runs: petroleum, naphthenic acids, asphaltogenic acids, asphaltenes, carbenes, carbides (cylinder carbon). Tests to det. the factors affecting the deposition of carbon in the engine indicate that conditions causing crank-case diln. must cause spraying of oil into the combustion chamber by the breaking of the oil seal of the piston rings, thus bringing about increased deposition of carbon. In general, the major factors of carbon deposition are: (1) amt. of lubricating oil projected into the combustion chamber, (2) kind of oil used, (3) temp. of the combustion chamber, (4) extent of time the preceding factors have been in effect. M. B. HART

Lead tetraethyl: its use in explosion engines as an anti-detonant. J. H. FRYDLENDER. *Rev. prod. chim.* 28, 685-8(1925).—A review. A. PAPINEAU-COUTURE

The hydrogenation and liquefaction of coal. III. The hydrogenation of brown coal, of Devonshire lignite and of low temperature coke obtained from Devonshire lignite. D. G. SKINNER AND J. I. GRAHAM. *Fuel in Science & Practice* 4, 474-85 (1925); cf. Shatwell and Bowen, C. A. 19, 2401.—Work was continued to det. the extent to which geologically more recent and more highly oxygenated coals could be converted into oil by hydrogenation at temps. and pressures similar to those of the earlier expts. A German brown coal and 2 English lignites, 1 much more recent than the other, were tested. Low-temp. coke was also hydrogenated at higher temps. to study the nature of the reaction. The yields of tar were much the same in brown coal and in the older ("normal") lignite, being in each case about 40% of the original dry, ash-free material. With the "recent" lignite the product sol. in CHCl_3 was only 0.75 that from the brown coal and "normal" lignite, but it consisted of more mobile tar yielding a greater proportion of volatile on distn. up to 300°. Hydrogenation of both the "normal" and "recent" lignite cokes gave smaller yields than the original lignites, and the amt. of CHCl_3 sol. material formed in the prepn. of the cokes did not account for these differing yields. Hydrogenation products sol. in PhOH but insol. in CHCl_3 were also obtained, the yield being very small with the "recent" lignite. A balance of the elements showed only very small losses with brown coal and the "normal" lignite, but with the "recent" lignite considerable loss of C, H and O occurred, probably because of the formation of phenols or acids, and possibly H_2O and low boiling oxygenated compds. Phenols were not formed in the hydrogenation of brown coal and the "normal" lignite. A comparison of the compn. of the products sol. in both PhOH and CHCl_3 with those from bituminous coals showed that the C/H ratio was greater in the products from brown coal and lignites. This was even more marked in the products of hydrogenation of the semi-cokes. The products sol. in PhOH but insol. in CHCl_3 and those sol. in CHCl_3 were formed by simultaneous hydrogenation and thermal decompn. of the original lignite. The hydrogenating action was probably due in part to the addn. of H at the moment of decompn. (depolymerization) of portions of the coal conglomerate as a result of heat treatment and in part to the direct action of H on certain mol. aggregates remaining in the residual coke. The influence of thermal decompn. on hydrogenation was more marked in the "recent" than in the "normal" lignite. In general the expts. indicated that under the particular conditions of temp. and pressure used the yield of tar oil was not appreciably greater with coals of recent geological age than with bituminous coals. C. C. DAVIS

Experiments on the combustion of pulverized coal. ÉTIENNE AUDIBERT. *Rev. Ind. minerale*, Jan. 1, 1924; *Genie civil* **84**, 231-4(1924). J. J. H., JR.

Thermodynamic and industrial bases of pulverized coal combustion. ROSIN. *Combustion* **13**, 94-5(1925); cf. *C. A.* **19**, 2735.—As with other forms of coal, the combustion of pulverized coal is a surface phenomenon. The ratio of the surface of the individual particle to its wt. is related to the combustion period by an hyperbolic curve. The disturbing influence of ash on combustion is not thermodynamic in nature but is due to the reduction in effective surface of the coal by the ash constituents. The combustion chamber must meet 2 fundamental specifications: (1) The fuel must burn completely in it. (2) The temp. of the inner refractory walls must be below their softening point, *i. e.*, there must be a transfer of heat to the body to be heated immediately after flame production. J. F. BYRNE

The length of visible flame and length of flame travel in combustion of powdered coal. HENRY KREISINGER. *Ind. Eng. Chem.* **17**, 1232-3(1925).—The length of the visible flame depends on the volatile matter of the coal, its compn., the amt. of primary air, and the method of mixing the coal and air. The combustion of the coke particles after the volatile matter has been driven off gives no visible flame, so that the length of the visible flame is no general guide to proper operation. The velocity of combustion of powd. coal is mainly dependent on the rate and manner of mixing of the gases and the fuel during combustion. WM. B. PLUMMER

The mechanism of combustion in the Bunsen cone. E. W. REMBERT AND R. T. HASLAM. *Ind. Eng. Chem.* **17**, 1233-6(1925).—Varying the temp. of the furnace walls surrounding a Bunsen flame from 110° to 1100° had no effect on the rate of combustion in the cone as detd. by analysis of the stack gases, which is in accord with the theory. Expts. made to det. the effect of port velocity, port diam., and air-gas ratio upon the height of the cone gave the following results. The rate of change of cone area decreases with increasing port velocity, becoming almost const. at high velocities; the rate of change of cone height decreases with the port diam., in some cases passing through a max.; the rate of combustion in the cone increases with increase in the primary air-gas ratio. These facts lead to the conclusion that heat transfer from the flame surface to the cold gas is the factor controlling the combustion of gas premixed with air. WM. B. PLUMMER

The development of a unit pulverizer (for coal). R. S. RILEY AND OLLISON CRAIG. *Mech. Eng.* **47**, 1045-52(1925). E. H.

The use of raw brown coal in the foundry drying chambers of the Krupp-Gruson works. W. TROLLIUS. *Braunkohle* **24**, 595-9(1925).—Shifting from coke to raw brown coal has reduced the B.t.u. requirements 43% and the fuel cost 73%. W. B. P.

Powdered coal transportation. WALTHER. *Braunkohle* **24**, 599-601(1925).—A brief discussion. WM. B. PLUMMER

The products of the distillation of coal: Installation of coke furnaces and recovery plant of the Société normande de metalurgie at Caen. A. GREBEL. *Genie civil* **84**, 585-93(1925).—Description with photographs, detail drawings and process diagrams. JACK J. HINMAN, JR.

Determination of heating value of coal in Monel metal bombs. J. C. GENIESSE AND E. J. SOOP. *Ind. Eng. Chem.* **17**, 1197-9(1925).—A study of the heat evolved through dissolution of the Monel metal in a combustion bomb has shown that if a suitable correction is applied, it is possible to reduce the error to less than 0.4%, even with coals contg. over 5.0% S. A bomb of Monel metal or a bomb with a Ni-lining will give corrected results well within the ordinary limits of accuracy of the method as a whole. The proper correction is obtained by titration of the liquid used for washing the bomb and comparison of the results with the total S of the coal. C. C. DAVIS

The Powell and Parr method for the determination of sulfur compounds in coal. T. G. WOOLMOUSE. *Fuel in Science & Practice* **4**, 454-6(1925).—The method of Powell and Parr (cf. *C. A.* **14**, 112) was used for the analysis of 12 coals of different types, as a result of which several conclusions are drawn. The dil. HNO₃ appears to be a complete solvent for the Fe compds. since the residues after extrn. with HNO₃ contained no Fe. With some coals the theoretical value for pyritic S is greater than the value detd. suggesting either that in these coals the difference between the Fe sol. in HNO₃ and that sol. in HCl is not true pyritic Fe, or that the formula for Fe pyrites in coal is not FeS but intermediate between FeS and FeS₂. With other coals the theoretical value for pyritic S is less than the detd. value, suggesting that the org. S in these coals is attacked by HNO₃. The method in general is fairly accurate, but it seems desirable always to est. Fe values together with S values so that some idea of the probable error involved may be obtained. The nature of the Fe compds. sol. in HCl varies from sample to

sample and includes ferrous compds., derivs. of hydrated ferric oxide and ferric compds. Complete analytical data are given. C. C. D.

Plant ash in relation to the inorganic constituents of coal. P. HAAS. *Fuel in Science & Practice* 4, 424-9(1925).—A survey of the quantity, distribution and nature of the ash of plants emphasizes the fact that too much reliance must not be placed on the value of an ash analysis as an indication of the nature of the plant material furnishing the ash. Accordingly caution must also be exercised in deducing from the ash analysis of a coal the nature of the plant from which it may have originated. Quant. data on the nature and compn. of the ash of numerous plants are included, with a description of the function of K, Ca, Mg, Fe, P, S and Mn. C. C. DAVIS

Washing coal by flotation: the treatment of dusts and slimes of high ash content. CH. BERTHELOT. *Genie civil* 84, 521-6(1924).—A promising scheme to treat material now wasted and recover the combustible material. Dutch national mines are now treating 100,000 metric tons per year. Also in *Chimie et industrie Special No.*, 154-62 (Sept., 1925). JACK J. HINMAN, JR.

Pulverized coal as applied to the steam boiler plant. W. E. EAST. *Proc. Illinois Eng. Soc.* 40, 75-80(1925).—Present specifications require 65% of coal to pass 200-mesh sieve. Formerly finer grinding was required. It was formerly thought necessary to dry coal to 1% moisture, but now it is considered necessary to dry it only to 5 to 8% moisture. Lignite contg. 24% moisture will be used at Denver. Advantages: (1) high boiler efficiency, (2) ability to burn high- and low-grade fuels with approx. the same efficiency, (3) ability to burn liquid, solid, or gaseous fuel in the same furnace, (4) low banking and stand-by losses, (5) ability to carry high over-loads for long periods, (6) ease of adapting to automatic control. JACK J. HINMAN, JR.

Moisture as a component of the volatile matter of coal. W. T. THOM. *Colliery Guardian* 130, 558-9(1925).—Moisture eliminated from air-dried low-grade coals below 100° is essentially the same as moisture liberated above 100° and is formed by analogous reactions. It is, therefore, essential to the formulation of a systematic classification of coals on a chem. basis to class all moisture forming a normal essential part of the coal as a sep. component and not as an extraneous impurity. The use of an air-dried sample in proximate analysis is the best method for distinguishing between accidental H₂O and that comprising a normal component. By plotting the % volatile (H₂O after air-drying included) against the calorific power for 800 samples the various types of coals could then be distinguished more clearly than by the usual dry basis. This was especially true with low-grade coals in which the H₂O in the air-dried coal increased the total volatile and decreased the calorific power much more than with high-grade coals and therefore allowed the various grades of coal to be distinguished more readily when plotted graphically. Low-grade coals such as lignites and sub-bituminous coals change rapidly on exposure to air, the volatile and the calorific power decreasing rapidly. This same degradation may take place geologically in coal seams over long periods of time. C. C. DAVIS

A routine apparatus for the determination of volatile matter in coal. A. E. BEET. *Fuel in Science & Practice* 4, 382(1925).—A set of SiO₂ crucibles (inside top diam. 24 mm., bottom 21 mm., height 39 mm., projections outside 27 mm. from bottom) with SiO₂ lids, resting in a SiO₂ rack and contg. 1 g. of sample in each crucible, is heated in an elec. muffle for 7 min. at 900°. The gases from the distn. are sufficient to maintain a reducing atm. Parallel expts. with Pt crucibles showed no appreciable differences in results. C. C. DAVIS

Fellner-Ziegler process of low-temperature carbonization. FR. SHÜTZ AND W. BUSCHMANN. *Iron Coal Trades Rev.* 111, 140, 182-3, 212-3(1925).—The economic factors in low-temp. carbonization are discussed. The value of lignite is greatly enhanced. The 20% yield of semi-coke contains 76.7% of the calorific value of the crude lignite and the tar—8.75% by wt.—has 12.8% of the calorific value. Small bituminous coal can be carbonized as cheaply as it can be briquetted, except the non-coking coals. These make better briquets after carbonization and, in addn., the by-products are recovered. Semi-coke has a calorific value of 6500-7500 cal. per kg., depending on the coal from which it was made, and can be used for coal dust firing, briquets, producer-gas furnace coke, mixed with strongly caking coals in coke ovens, as an intermediate product in the liquefaction of coal, i. e., to be converted to CO and H for high-pressure synthesis. The tar can be used as a source of motor fuels, chem. agents, impregnating oil, etc. Low-temp. tar fractions between 200° and 300° contain 40-50% phenols with the remainder mainly aromatic hydrocarbons of the benzene series, and 5% satd. hydrocarbons of the paraffin series. Coke-oven tar, between 200° and 300°, is mainly aromatic, with only 3-6% phenols. Lubricating oil extn. from low-temp. tars is impracticable,

the only present uses for the tar being liquid fuel, impregnating oils and disinfectants. The benzene obtained makes a very desirable motor fuel. Its chem. compn. is more complicated than coke-oven light oils or petroleum, and consists of paraffins 10-25%, diolefins 1-5%, aromatic hydrocarbons 25-60%, naphthenes 1-2%, ketones 1-2%, aldehydes, S and N compds., and phenols. Gasol, the liquid mixt. that boils below 30°, contains 10,000 cal. per kg., and is excellent for cutting and welding. The operation of the Fellner-Ziegler plant at Frankfurt, which uses the compression method for recovering benzene and gasol, is described. J. F. BYRNE

Recent progress in the peat problem. R. M. PERKIN. *Colliery Guardian* 130, 556-7(1925).—A review and discussion of present developments in the drying, briquetting and distn. of peat, with a description of a new method devised by P. The latter consists essentially of macerating the peat and extruding as much H₂O as possible, then heating it in an autoclave under pressure, suddenly discharging it by a sluice valve, filtering and finally pressing into briquets which are hard and contain only 18-20% H₂O. When carbonized these briquets give a charcoal which is superior to Swedish charcoal for the manuf. of steel. A typical analysis gave 83.5% fixed C and very low P and S and volatile. Analyses and yields of distn. products from peats are also given. C. C. DAVIS

Industrial importance of Rumanian natural gas. P. STACHELIN. *Mon. Petr. Roum.* 24, 971(1925).—The principal use of the natural gas is the production of mechanical and elec. energy. A plant was established in Sarmas for the production of nitrogen oxide according to the process of Bender by direct combustion of the natural gas with air. At a temp. of 2000°, 1% of nitrogen oxide is formed. This process was abandoned later because the furnace walls did not resist the high temp. By passing natural gas over heated quicklime, H was obtained besides Ca contg. 50% C, which can be preferably used in blast furnaces. Martin Bank has a Rumanian patent according to which 33.8% by vol. of acetylene can be obtained by passing methane through an elec. furnace at a temp. of 1400°. M. B. HART

The choice of properties for gas. KARL BUNTE. *Gas u. Wasserfach* 68, 587-90, 607-10, 623-5(1925).—Gas properties are discussed, in particular the mixing of coal and water gas to obtain the properties desired for various purposes. The operation of the Bergius process as a gas plant adjunct is also discussed. WM. B. PLUMMER

Use of oxygen in the manufacture of water gas. F. E. VANDAEVER WITH S. W. PARR. *Ind. Eng. Chem.* 17, 1123-7(1925).—It is estimated that O₂ at 25 cents/1000 cu. ft. will certainly, at 50 cents may possibly, compete with air in gasification processes. Tests on a small generator (approx. 5 × 10 in. section × 5 ft. high, inside) burning coke without steam used 0.417-0.512 cu. ft. O₂/cu. ft. gas made, the final gas being somewhat over 200 B.t.u./cu. ft. and contg. 60-70% CO and 10-15% CO₂. Similar tests with steam and the min. amt. O necessary to sustain the reaction gave results as follows: 920 lbs. steam with 20,562 cu. ft. O₂ gave 66,000 cu. ft. gas, all per ton coke; the gas was 254 B.t.u./cu. ft., contg. 10.4% CO₂, 57.6% CO, 20.7% H₂, 0.6% O₂, 10.7% N₂. In both producer and water gas tests suction was used on the generator; temps. were sufficient to slag the ash but caused no operating difficulties. WM. B. PLUMMER

The removal of benzene from gas: the present state of the matter in France. A. GREBEL. *Genie civil* 87, 37-43, 53-7(1925). JACK J. HINMAN, JR.

Factors influencing length of a gas flame burning in secondary air. F. W. REMBERT AND R. T. HASLAM. *Ind. Eng. Chem.* 17, 1236-8(1925).—Expts. on the effect of port velocity, port diam., and primary air-gas ratio on the length of a flame burning in free space show that the length is expressed by the equation $L = K \log u + B \log D + E$, where u is the port velocity and D the port diam., the consts. K and B being dependent upon the furnace construction, and also upon the primary air-gas ratio. These consts. are tabulated for various cases. WM. B. PLUMMER

Factors affecting the utility of secondary air in gaseous combustion. F. W. REMBERT AND R. T. HASLAM. *Ind. Eng. Chem.* 17, 1238-40(1925).—With increasing air supply the ratio of air utilized/supplied passes through a max., the actual values depending on port diam. and velocity. For a given air supply the ratio of air utilized/supplied increases with both port velocity and diam., probably because of increased rate of mixing. WM. B. PLUMMER

Relative rates of combustion of constituents of city gas burning in secondary air. F. W. REMBERT AND R. T. HASLAM. *Ind. Eng. Chem.* 17, 1240-2(1925).—Provided that over 80% of the gas has already been burned, the relative rates of combustion of the various constituents of city gas may be approx. expressed by the following ratios: C₂H₄/CH₄ = 1.1, H₂/CO = 4.9, CH₄/H₂ = 3.0, CH₄/CO = 14.9. These results were obtained by detn. of flue gas compn. for various controlled conditions. W. B. P.

Chemical equilibrium in gases exhausted by gasoline engines. W. G. LOVELL WITH T. A. BOYD. *Ind. Eng. Chem.* 17, 1216-9(1925).—Numerous data on the compn. of engine exhaust gases have been examd., it being found that the *water gas equil. const.* $K = (\text{CO})(\text{H}_2\text{O})/(\text{CO}_2)(\text{H}_2)$ calcd. from them lies, for practically all cases of load, carburetor adjustment, etc., between 3.0 and 4.0, which corresponds to an apparent equil. temp. of 1350-1550°.

WM. B. PLUMMER

Experiments on the flow of gas in long pipe lines between Saint-Quentin and Noyon. COMMISSION DE DISTRIBUTION, 48TH CONGRÈS DE LA SOCIÉTÉ TECHNIQUE. *J. usines gaz* 49, 260-8, 275-85(1925).—A detailed report of expts. on coal gas, water gas and city (mixed) gas at various rates of flow in various pipe lines. The results have been compared to those calcd. by the Girard, Unwin, Towl, Mommer, Arson, Weymouth-Towl and Chicago formulas. Of these the last is accurate to 1% for initial pressures of over 1 kg. This is much closer than with any of the other formulas. W. B. P.

Contribution to the study of the gas producer. G. HUSSON. *Rev. ind. minérale* 1925, 451-72.—A discussion of the *theoretical relations between the temp. gradient of a gas producer using coke and the compn. of the gas*, with their application to the practical operation of the producer. In effect the article is an amplification of a previous one (cf. *C. A.* 16, 4327). The determinant factors governing the operation of such a producer are the insulation of the equipment, the reactivity of the coke and the softening temp. of the ash, the first two of which have heretofore been too little appreciated. The insulation detcs. the temp. of the zone where the ratios CO/CO_2 and $\text{H}/\text{H}_2\text{O}$ are max. and the rate at which combustion should be carried on to obtain max. efficiency. It is shown to be of great advantage to have a very reactive coke and so a gas producer using coal should be so operated that the distn. in the upper region yields a coke of max. reactivity. Theoretically ideal conditions are modified in practice by the fact that the softening point of the ash limits the temp. of the hot zone, the efficiency becoming less above this temp. because of mech. troubles caused by fusion of the ash. Further considerations, such as the effects of steam injection, the max. temp. of combustion and the application of the theories derived for coke gas producers to producers using coal, are discussed in a way which does not admit of brief exposition.

C. C. DAVIS

Conditions governing the efficiency of gas burners. S. W. PARR. *Ind. Eng. Chem.* 17, 1215-6(1925).—A brief discussion of the inefficiency of ordinary gas burners, and of the advantages of increasing the primary air and the gas pressure in burners of the Bunsen type.

WM. B. PLUMMER

New apparatus for the determination of carbon dioxide in flue gases. CAILLOT. *Rev. ind. minérale*, Jan. 15, 1924; *Genie civil* 84, 415(1924).—As the CO_2 increases in the flue gases their heat cond. decreases. Two Pt wires, one in the air and one in the flue gases, are heated by the same elec. current. The wire in the flue gases gets hotter as the CO_2 increases and its resistance increases. The amt. of CO_2 and the resistance therefore vary similarly. A recording galvanometer is used.

J. J. H. JR.

Vapor composition relationships in the systems phenol-water and phenol-cresol. F. H. RHODES, J. H. WELLS AND G. W. MURRAY. *Ind. Eng. Chem.* 17, 1199-1201(1925).—PhOH and H_2O form azeotropic mixts. which have min. boiling points, the proportion of PhOH in the const.-boiling mixt. decreasing with the pressure. Thus at atm. pressure the mixt. contains 9.4% PhOH and at a pressure of 260 mm. 4.4% PhOH. The concn. of PhOH in the distillate remains approx. const. as long as its concn. in the liquid is over 85% or so. Comparison of exptl. and calcd. data (cf. *Z. physik. chem.* 26, 603(1898)) of the vapor compns. indicates that PhOH forms "ideal" liquid mixts. with *o*-, *m*- and *p*-cresol. The complete data allow the calcn. of the theoretical min. reflex ratio and the min. no. of sections required in the fractionating columns of stills for the sepn. of PhOH from H_2O and from cresols.

C. C. DAVIS

The testing of coke. G. E. FOXWELL AND R. V. WHEELER. *Fuel in Science & Practice* 4, 410-3(1925); cf. *C. A.* 19, 3368.—The CO_2 , O and air methods for detg. the combustibility and reactivity of coke and the general principles involved in methods for detg. its temp. of ignition are described and criticized. The CO_2 method prescribes 950°, so that cokes made below this temp. are superheated before the actual detn. Furthermore crushing destroys the macrostructure and exposes an undue amt. of the interior of the cells to CO_2 , which have a different reactivity from the surface, and therefore the mean reactivity differs from coke in bulk. When the finest material is discarded the reactivity is abnormally low. In the O method the order of the rates of reaction of different cokes is not the order of their rates at other temps. In the air method channeling is likely, difficulty is encountered in maintaining a const. height of bed and there is no temp. control, but in spite of these short comings the air method using a grate area of 1 sq. ft. appears to be the most satisfactory. The ignition temp.

method is of doubtful value in that the ignition temp. of coke is not necessarily a function of its combustibility.

C. C. DAVIS

New continuous vertical chamber ovens. O. PEISCHER. *Gas u. Wasserfach* **68**, 596-7(1925).—Results of several tests show no decrease in coke quality in continuous ovens as compared to intermittent ovens of the same dimensions.

W. B. P.

The gasification of molasses residues (MUEHLERT) **28**. $\text{CO}_2\text{-NH}_3$ compounds (MEZGER, PAYER) **2**. Air pollution (KERSHAW) **14**. Rational use of conduits for transporting water and gas (GILBERT) **14**. Kiln for drying and carbonizing coal (U. S. pat. 1,556,571) **1**. Apparatus for drying wet coal (U. Hydrocarbon gases from coal, etc. N. G. LINDERBORG. U. S. 1,528,623, March 3, 1925. In producing gas from coal, gasoline and other products from kerosene, or in carrying out other similar reactions, the raw materials are passed successively through hotter zones of a furnace partially heated by elec. devices adjacent the extreme end of the furnace and volatilized products are subjected to high-tension elec. discharges from rapidly moving electrodes.

Gravity separation apparatus for testing coal and separating impurities from it. G. R. DELAMATER. Brit. 232,942, April 26, 1924.

Benzene, etc., from heavy oils. E. A. BARBET. U. S. 1,561,899, Nov. 17. A mixt. which may comprise a heavy non-volatile oil and substances absorbed from coke-oven gas is first heated by heat of out-going stripped oil and by vapors of C_{10}H_8 coming from a heating of the oil to a higher temp. at a later stage. The oil thus preheated is then run through a still and rectifying column and heated by indirect steam heat to about 160° while vapors are drawn off from the lower portion of the rectifying column, and is then further heated by superheated steam to a temp. which will vaporize C_{10}H_8 .

Apparatus for distilling benzene, etc., from wash oils. KOPPERS COKE OVEN CO., LTD. Brit. 232,724, Feb. 9, 1924. The app. is arranged so that circulation of the oil is not affected by the degree of reduced pressure in the app.

Apparatus for washing benzene and light oils from gas works, etc. K. PFISTERER. Brit. 232,730, Feb. 20, 1924.

Apparatus for testing the explosiveness and explosion pressure of motor oils and fuels. H. JENTZSCH. Brit. 232,633, April 20, 1924.

Liquid seal valve device for gas manufacturing plants. ASKANIWERKE AKT. GES. FORM. CENTRALWERKSTATT-DESSAU AND C. BAMBERG-FRIEDENAU. Brit. 232,937, April 26, 1924.

Gas scrubber. H. BAUER and G. TAUBE. Brit. 232,590, April 15, 1924.

Apparatus for separating tar from producer gases by scrubbing and baffling. B. MOSCOVITCH. U. S. 1,562,118, Nov. 17.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Progress in petroleum engineering. W. R. ECKART, et al. *Mech. Eng.* **47**, 1126 (1925).

E. J. C.

Chemistry of petroleum. II. Action of sodium hypochlorite on sulfur compounds of the types found in petroleum distillates. S. F. BIRCH AND W. S. G. P. NORRIS. *Chem. Soc.* **127**, 1934-44(1925); cf. *C. A.* **19**, 2407.—Solns. of Et_2S , dipropyl sulfide, diisobutyl sulfide and diisoamyl sulfide dissolved in naphtha ($100\text{--}175^\circ \text{ b. p.}$) were made to have S contents of approx. 1%. All were oxidized wholly or in part to the analogous sulfones when shaken (15 min.—2 hrs.) in equal vol. with a soln. of NaOCl (8.42% of available Cl). The % of free alkali (NaOH) influenced greatly the rate of the reaction, the most active solns. contg. relatively little excess of NaOH (0.22%). Solns. of org. sulfides give rise under similar conditions to sulfonic acids and sulfuric acid. The reaction of these products with NaOH must be considered in prepg. the soln. of hypochlorite, which in practice should remain alk. Mercaptans in fairly alk. solns. are oxidized largely to the disulfides. In less alk. solns., the products are the same as those of the analogous disulfides. The activity of the hypochlorite is increased by diln. and by decrease of concn. of OH . Elementary S is not attacked. H_2S is oxidized to

H₂O and S, and there is evidence that some H₂SO₄ is formed simultaneously. Thiophene is not oxidized. W. F. FARAGHER

Analysis of crude oils of Roumania. G. GANE AND A. MOSCHUNA. *Mon. Petr. Roum.* **24**, 950-60(1925).—Samples of all the Roumanian crudes were studied to det. (1) the d₁₅, (2) color, (3) point of liquefaction and (4) the paraffin content at -20°. M. B. HART

Absolute viscosity of the Roumanian petroleum. C. PREDESCO. *Mon. Petr. Roum.* **24**, 1248(1925).—The method used is described and a table contg. the exptl. results is given. The abs. viscosity with the b. p. of the fraction 100-110° is 0.004891 and 0.1703 for the fraction 340-350°. It increases much faster than the surface tension. Up to the fraction 200-210°, the absolute viscosity increases in straight line; from this fraction up to 300-310°, it increases faster; then up to 340-350°, it increases much faster. The surface tension increases in nearly a straight line. The variation of the absolute viscosity with the temp. for the heavy fractions is much greater than for the light fractions. M. B. HART

Chemical problems in the water-driving of petroleum from oil-sands. P. G. NUTTING. *Ind. Eng. Chem.* **17**, 1035-6(1925).—Exptl. results of displacing oil by water from spaced plates of glass and from sand are described and discussed theoretically. Na₂CO₃ is particularly effective in enabling H₂O to displace petroleum. Its use is being tested in the Bradford district (Pa.). W. F. FARAGHER

Developments in American refining methods and equipment. J. T. B. BOWLES. *Oil Trade* **16**, No. 8, 27-8(1925). M. B. HART

Petroleum motor fuel. K. G. MACKENZIE. *Ind. Eng. Chem.* **17**, 1105-14(1925).—A historical account of the production of motor fuel is presented statistically (domestic and foreign). Factors of conservation are discussed and emphasized. W. F. F.

Mazut. E. DAWKIN. *Chem. Tech.-Ztg.* **43**, 113-5(1925).—The physical properties of mazut (fuel oil) are given. Suitable methods of combustion are discussed. M. B. HART

Mazut (fuel oil). I. DAVIN. *Chem. Tech.-Ztg.* **43**, 113(1925).—Well-known methods of testing fuel oil are mentioned. Special attention is paid to its use in burners of different types as follows: (1) burning in a pan; (2) preheating and burning the gas; (3) atomizing by compressed air; (4) atomizing by superheated steam. Atomization is the most economical on boats. A rapidly rotating atomizer is used, the fuel being preheated. M. B. HART

Wastage and salvaging of oil at tanks in Salt Creek Field, Wyo. J. S. ROSS. *Nat. Petroleum News* **17**, No. 29, 58(1925).—Effective tank drainage and waste oil recovery systems in use include: wooden drain and sump boxes together with a steam pump to remove to 50-barrel tank, in which drain connections discharge downward into the boxes; drains around the bases of tanks, either ditches or concrete drains; the use of ponds, dams or earthen sumps to catch wastage is poor, for the oil is difficult to recover. Satisfactory collectors are small wooden or concrete sump boxes "Tank bottoms" and "burnt oil" may be treated effectively by steaming with care for 4¾ hrs. on one day and 2½ hrs. the next day, the temp. being raised from 50° to 160° F. After steaming the oil was allowed to stand for four days when but 2% bottom settlings and emulsion were present as compared to 5 to 12% before steaming. Conditions for proper steaming include: No live steam should come in contact with the oil; heat until all is at the desired temp., let steamed oil stand until all free water and bottom settlings have settled; keep tank tops tight to keep out moisture. M. B. HART

Extraction of gasoline by absorption. L. H. HILE. *Oil & Gas J.* **24**, No. 10, 186(1925).—The oil absorption method is described and commended because of its application to gases of any gasoline content under varied pressures, and its simplicity of operation. M. B. HART

Engineering increases the capacity of gasoline plant at minimum cost. J. C. CHATFIELD. *Nat. Petroleum News* **17**, No. 33, 36-38(1925).—It is recognized by natural gasoline engineers that 50% of the absorption oil circulated will ext. 80% of the gasoline, while the rest is necessary to absorb the remaining 20%. The Phillips Petroleum Company will double the gas flow through the absorbers, extg. about 80% of the available gasoline and pass the gas through three 7 × 30 foot horizontal charcoal absorbers to recover the remaining 20%. The gas will be passed from the oil absorber through two 7 × 30 foot horizontal scrubbing tanks to remove all absorber oil. M. B. H.

Gasoline manufactured from California crude has superior quality. ROY CROSS. *Oil Age* **22**, No. 8, 11, 12(1925).—The various types of anti-detonating gasolines are discussed with curves to show volatility gravity relations of various types. An app. and method for detn. of gasoline content are described. The relative value of fuels in

regard to anti-detonating properties for carboned cylinders or high-compression motor, is approx.: benzene-gasoline, synthetic gasoline from cracking coal tar gas oil, synthetic gasoline from cracking kerosene under high pressure, California natural gasoline, synthetic gasoline from cracking paraffin-base petroleum, Mid-Continent natural gasoline, pure paraffin base gasoline.

M. B. HART

Prevention of evaporation losses from gasoline storage tanks. R. E. WILSON, H. V. ATWELL, E. P. BROWN AND G. W. CHENICEK. *Ind. Eng. Chem.* **17**, 1030-5 (1925).—The process of "breathing" of tanks is discussed fully. Breather-bags of canvas, rendered impervious by a dope consisting of high-grade glue and glycerol and coated, after drying, with talc to prevent adhesion of surfaces in contact, are connected to breather-pipes of tanks. A bag 25 ft. in diam. and 45 ft. long (18,000 cu. ft.) will serve two 40 × 120 ft. gasoline tanks. The bags are housed in a sheet-metal building. Loading, seals, performance, durability and costs and savings are discussed. W. F. F.

Motor design and fuel economy. C. F. KETTERING. *Ind. Eng. Chem.* **17**, 1115-6 (1925).—A discussion of ideal requirements for a motor car, and the departures from them forced by the demands of the purchaser.

W. F. FARAGHER

The "cracking" of paraffins. A. WILLIAMS-GARDNER. *Fuel in Science & Practice* **4**, 430-40 (1925).—With the ultimate object of detg. the chem. changes involved in the cracking of oils, a study was made of the thermal decompn. of the simplest compd. capable of being cracked, viz., C_2H_6 . At pressures slightly below normal C_2H_6 begins to decomp. at 550°. Decompn. is very slow, and secondary changes do not occur at this temp., the chief products being CH_4 and C_2H_4 with traces of H. At slightly higher temps. the C_2H_4 has a tendency to be hydrogenated by the H present, forming CH_4 and at the same time undergoing slight decompn. into C and H. The intermediate formation of C_2H_2 is extremely doubtful and at no time during the thermal decompn. of C_2H_6 does C_2H_2 appear in appreciable quantity nor does it play an important part in the different reactions taking place at any temp. Up to 800° conditions favor the formation of liquid products, but above 800° there is a strong tendency for C_2H_6 and C_2H_4 to decomp. into their C and H and at the same time to be hydrogenated to CH_4 . At still higher temps. decompn. of CH_4 into C and H sets in. Contrary to the expts. of Bone and Coward (*C. A.* **2**, 3061) aromatic compds. were formed in considerable quantities and C_6H_6 was one of the chief liquid products. This formation of aromatic compds. is ascribed to the behavior of C_2H_4 in the region of 750°. At such temps. the predominant secondary change is apparently the polymerization of an unsatd. compd. with elimination of H. The mechanism of the changes can be explained on the assumption that there is a scission of the C-C bond in the C_2H_6 mol., giving rise to Me residues which are stable at temps. around 550°. With rise in temp., however, these residues are dissociated to the more unsatd. and perhaps less stable $:CH_2$ residues, which form equil. mixts. with C_2H_4 , H being at the same time eliminated. With rise in temp. Me groups are hydrogenated to CH_4 and H, while the reaction $:C_2H_4 \rightleftharpoons :CH_3 + :CH_2$ proceeds from left to right, the unstable $:CH_2$ residues undergoing either (1) decompn. into $:CH$ residues and H (the former polymerizing to liquid products or decompng. into C and H); (2) hydrogenation to CH_4 or (3) direct decompn. to C and H. The $:CH$ residues may be considered to have more than the "fugitive sep. existence" attributed to them by Bone and Coward (*loc. cit.*), for C_2H_2 is formed from C and H above 1000° (cf. *J. Chem. Soc.* **89**, 1591 (1906)) and it is probable that at such temps. C_2H_2 does not exist but that CH residues are stable. In general the thermal decompn. of C_2H_6 is typical of the decompn. of a paraffin to form a lower paraffin or an olefin in the manner suggested by Haber, Thorpe and Young and others. Subsequent changes are due to the secondary decompn. of the products. The app. and methods used in the expts. are described and illustrated, besides which a bibliography of 26 references is included. C. C. D.

N. T. U. Company building for eduction of shale in large quantity. L. E. SMITH. *Nat. Petroleum News* **17**, No. 33, 30 (1925).—The process is based upon the principle of a down draft within a vertical steel shell with a controlled zone of combustion. All fuel for the internal heating of the generator is supplied from the shale itself. Temp. control is effected by returning some of the gaseous products of combustion through the air feed pipe to the top of the generator. The oil produced is condensed in the cool shale below the zone of distn. or in the condensing and scrubbing app. 68 to 88.3% recovery of available oil and gasoline at a cost of 65-70 cents per ton of shale distd. is possible from a plant costing \$400,000. The shales used have not been true oil shales but a diatomaceous earth satd. with a bituminous substance similar to asphalt which is sol. in gasoline, but tests on kerogen shale showed a 96.0% recovery. The Cross cracking process produced an ultimate yield of 78% gasoline and 22% gas and coke from samples of the oil.

M. B. HART

A general survey of the economics of the oil-shale industry. R. B. DAY. *Pet. World Calif.* 10, No. 8, 30, 31, 114(1925). M. B. HART

Charcoal adsorption plant set up in eight days making money from gas of one well. J. C. CHATFIELD. *Nat. Petroleum News* 17, No. 32, 63, 64, 66(1925).—Charcoal adsorption has been used efficiently on rich gas by the Skelly Oil Co. by means of three 6 by 8 foot absorbers contg. 7000 lb. of activated charcoal running on 30-min. cycles. Gas enters the system at 5 lb. well pressure per sq. in. and is being handled at the rate of 950,000 to 1,000,000 cubic feet per day without the use of scrubbers. The charcoal is cooled to 135 to 145° by the residual gas before reabsorbing, leaving only 60 to 66 gallons of gasoline per million cu. ft. of gas. M. B. HART

Colorado oil shales. W. C. ALDERSON. *Petroleum Times* 14, 227(1925).—Oil shale is found in all periods of geological formation and can be classified as a natural deposit resulting from the deposition of org. matter from plants and animals of a former geological period. Oil shale contains ferns, leaves and fish scales, besides pollen, insects and other remnants of plant and animal life, but no oil as such. Since H and C are present a proper distn., in an air-tight retort at about 800° F., produces oil and gas. Tables are given which show the potential supply and approx. relative value of oil shales in the United States. M. B. HART

The present status of the oil-shale industry in Esthonia. P. N. KOGERMAN. *J. Inst. Petroleum Tech.* 11, 210(1925).—A short history of the development and method of operation of the oil-shale industry in Esthonia is given. Kukersite, the Esthonian oil shale, produces 20% of its wt. of oil. The gas produced by carbonization in old-type horizontal retorts contains H 37.6, methane 25.8, CO 19.1 and CO₂, etc., 13.3%. The oil yield is greater from unweathered shale and contains hydrocarbons 72.1, phenols 22.4, carboxylic acids 4, bases 0.2%. Shale oil is at present the cheapest crude oil in Esthonia. M. B. HART

Control of consistency in manufacture of cup-grease. D. R. MERRILL. *Ind. Eng. Chem.* 17, 1068-71(1925).—The general method of making cup-greases is discussed briefly. An *Abraham consistometer* was used to det. consistencies of commercial grades of lime-soap cup-greases. A control test during manuf. involves cooling in the air for 15 min. A sample (judged by quantities of oil, etc. used and "by feel" of an air-cooled sample to be slightly too hard) in a spice can (1 1/4" X 2 1/4" X 3 1/8") is cooled in the air during 15 min., and is then chilled for an hour in crushed ice and water. Two tests are made on each can. The quantity of oil to be added is known from previous tests for the particular grease. Temp. at which grease is finally drawn into the containers is important. W. F. FARAGHER

Density of a lubricating oil at temperatures from -40° to 20°. H. K. GRIFFIN. *Ind. Eng. Chem.* 17, 1157-8(1925).—A special pycnometer and the method of using it are described. Determinations of density are accurate to 1 part in 1000. W. F. F.

Decolorization of lubricating oils by the contact method. A. R. MOORMAN. *Nat. Petroleum News* 17, No. 29, 84(1925).—Contact filtration which produces oil of uniform color and eliminates grading allows clay to be used directly on sour oils from acid treat, thus eliminating neutralization. Action of clays is entirely selective, and is independent of temp. (up to 500° F.). The decolorizing power is ordinarily independent of the acidity of the oil, being greater in contacting a sour oil, and increases with rise in temperature. Steam should be present until the clay is removed from the oil, which makes a continuous process preferable. Natural clays are lower in efficiency and price than treated clays and are best adapted to use on gasoline and neutralizing lubricating oils while treated clays are better decolorizers. Clays are used either dry or in the form of a pulp, the latter being more efficient, after they have been treated with acid and washed. M. B. HART

Increasing viscosity of lubricants. E. C. ISOM. *Oil & Gas J.* 24, No. 13, 156 (1925).—"Voltol" is a lubricant manuf. by subjecting fatty and mineral oils to an elec. glow discharge of 4000 v. at 500 cycles. The process is covered by the German patents 234,543, 236,294, 185,931. It is carried out in a closed horizontal cylindrical steel vessel of 30 cu. m. content, under a reduced pressure of 24-26 inches of Hg with the addition of no other gas. Since the oil is held at 80°, vapors are formed and the "voltolizing" is carried on in a rarified atm. of oil vapors. None of the properties is affected except the viscosity, but the friction reduction often amounts to 30%. "Normal voltol" is a compounded oil with a viscosity of 1500 Saybolt at 212° F., consisting of a mixt. of fatty oil with mineral oil. Uses of the lubricant include lubrication of internal-combustion engines, high-pressure compressor, superheated steam cylinders, marine engines, heavily loaded ring-oiling bearings, etc. The process increases the viscosity of an oil 300% without affecting its original pour test. M. B. HART

Low-grade crude available for lubricants. J. W. WEIR. *Oil & Gas J.* **24**, No. 17, 24, 84-6(1925).—Mixed-base crude is reduced to asphaltum, the lubricating stock is reduced to viscosity and the wax sepd. by filtering through clay, usually clay that has already been used for decolorizing purposes. The wax is then removed from the clay by extn. with a solvent, the soln. filtered from the clay and the clay used over again together with a certain additional amt. of fresh clay. M. B. HART

Identification of Norit and other wood charcoals. H. G. TANNER. *Ind. Eng. Chem.* **17**, 1191-3(1925).—Charcoals prepd. by heating various types of wood in the presence of insufficient O all contain occasional particles having a perforated structure characteristic in size and pattern of the particular genus of wood used, varying somewhat in the various species within the genus, and independent of the exact conditions of prepn. Norit (a Dutch com. active C) has thus been identified as apparently made from birch wood, and a charcoal prepd. as above from birch (yield 7%) has been found to have the same decolorizing power as Norit. Photomicrographs are given of characteristic particles from a no. of woods. WM B. PLUMMER

The carbonization oven competition of the Sénart forest (France). ANON. *Recherches et inventions* **7**, 789-809(1925).—The Frey, Laurent, Camille Rochet, Delhommeau, Krug, Magnein and Trihan portable carbonization ovens and their method of operation are described. Their comparative performances during the competition are given. A. PAPINEAU-COUTURE

Hydrocarbon gases from coal (U. S. pat. 1,528,623) **21**. Bituminous liquid coating compositions (U. S. pat. 1,558,082) **26**. Tetraalkyl lead (U. S. pat. 1,559,405) (U. S. pat. 1,550,940) **10**.

Refining petroleum oils. J. F. FABER, H. C. HANNA and M. L. CHAPPELL. U. S. 1,562,156, Nov. 17. After treating oil with H_2SO_4 , the treated oil is sepd. from the acid sludge and neutralized in the presence of a "petroleum carboxylic salt" to prevent the formation of a persistent emulsion, this "petroleum carboxylic salt" being obtained by extg. "petroleum carboxylic acids" from crude petroleum oil by use of an aq. soln. of a metallic base so as to avoid the presence of sulfonated soaps.

Gases containing olefinic hydrocarbons. GOLDSCHMIDT AKT.-GES. Brit. 232,568, April 15, 1924. Pennsylvania gas oil or a similar oil is passed through a bath of molten Pb or the like maintained at about 600-650° and the resulting gases are freed from undecomposed oil, "benzines" and diolefins by cooling, compression or absorption. They consist of CH_4 , C_2H_4 , C_3H_6 and C_4H_8 . C seps. on the surface of the Pb bath.

Removing wax from hydrocarbon oils. A. GREENSPAN. U. S. 1,562,425, Nov. 17. Kerosene 15-20% is added to oil to effect the crystn. of cryst. wax at a temp. of about 27-32°. The oil is then sepd. from the wax crystals and amorphous wax and kerosene are distd. off from the sepd. oil until the residuum in the still is a high-grade cylinder stock.

Rectification of alcoholic or hydrocarbon liquids. E. A. BARBET. U. S. 1,559,218, Oct. 27. In rectifying mixed liquids such as petroleum oils or "benzols," heat is supplied to the mixt. to vaporize its lower b. p. constituents at atm. pressure. Vapors formed are condensed, and the heating of the residual liquid is interrupted and it is subjected to a reduction of pressure while still hot, the vapors thus formed are fractionated and the liquid residue from the fractionation is further subjected to multiple effect evapn. *in vacuo*.

Dephlegmator for hydrocarbon vapors. F. LAMPOUGH. U. S. 1,557,478, Oct. 13.

Cracking petroleum oil. G. EGLOFF. U. S. 1,561,779, Nov. 17. Oil is passed through a heating coil where it is subjected to cracking conditions of heat and pressure. A portion of the oil is then transferred to a primary expansion chamber and all of the oil constituents are transferred from this chamber into a secondary chamber. The remaining portion of the heated oil from the coil is directly introduced into liquid oil in the secondary chamber to increase the amt. of conversion.

Still for cracking petroleum oil. G. W. WALLACE. U. S. 1,561,758, Nov. 17. Vertical tubes through which the oil is circulated (and which are heated by combustion products to effect cracking of the oil) extend between upper and lower headers. From shaves in these headers, chains pass through the tubes and by their movement prevent collection of C deposits in the tubes.

Apparatus for fractional distillation of petroleum. H. P. STRAUS. U. S. 1,562,009, Nov. 17. The app. comprises a column with perforated plates.

Decolorizing oil. P. W. PRUTZMAN and C. J. VON BIBRA. U. S. 1,562,001, Nov. 17. An aq. mud is prepd. from pulverulent solid decolorizing material to exclude all

from the pores of the material. This mud is mixed with oil to be decolorized, *e. g.* petroleum lubricating oil, and the mixt. is heated until the H_2O is evapd., the spent decolorizing material being then sepd. from the oil.

Purifying and decolorizing oils. P. W. PRUTZMAN. U. S. 1,561,999, Nov. 17. A portion of petroleum oil of high b. p. or other similar oil to be decolorized is mixed with powd. porous adsorbent material such as fuller's earth, boneblack or acid-treated montmorillonite and the mixt. is allowed to stand until air has been displaced from the pores of the adsorbent by the oil. The remainder of the oil is heated to a temp. above 175° and mixed with the adsorbent and its associated adsorbed oil to effect a partial decolorization. The adsorbent is then sepd. Cf. C. A. 19, 3013.

Removing acids from oils. P. W. PRUTZMAN and P. D. BARTON. U. S. 1,562,000, Nov. 17. In removing acid-tar from acid-treated petroleum oil contg. tar, the oil is agitated with adsorbent clay or other powd. adsorbent which has been previously used for removing impurities from tar-free oils and is charged with tar-free oil.

Retort for distillation of shale, coal, etc. W. GUY-PELL. U. S. 1,558,671, Oct. 27. See Brit. 223,652 (C. A. 19, 1192).

Bituminous emulsions. H. A. MACKAY. Brit. 232,683, Jan. 23, 1924. The process of Brit. 202,021 and 202,235 (C. A. 18, 326) is modified by effecting the prep. of the emulsion at a lower temp., about 88° , in an agitating app.

Bituminous composition for use in block or sheet form, etc. G. J. MULLER. U. S. 1,559,731, Nov. 3. Bituminous material such as asphalt is mixed with finely divided slate contg. graphitic C, *e. g.* with Peach Bottom slate.

Metallic lubricant-carrier. A. E. BECKER. U. S. 1,562,138, Nov. 17. Metallic lubricant-carrier material such as steel, Cu, brass or Monel "wool" is heated in the presence of a S-contg. oil, *e. g.* heavy distillate from Mexican petroleum oil, to increase its holding capacity for lubricant.

Refining gum turpentine. A. R. AUTREY. U. S. 1,559,399, Oct. 27. Gum turpentine or similar substances to be refined and decolorized is agitated with dried fuller's earth, preferably at a temp. of about $57-68^\circ$, and then filtered and distd. with steam at a temp. not exceeding about 155° .

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Reactions relating to carbohydrates and polysaccharides. XI. Oxidation of cellulose. HAROLD HIBBERT and J. L. PARSONS. *J. Soc. Chem. Ind.* 44, 473-85T (1925).—From expts. on the oxidation of purified cotton cellulose, 22-26% over the oxidizing range 0.01-2.00 atomic portions O per $C_6H_{10}O_5$ unit using $KMnO_4$, $Mg(MnO_4)_2$ and $Ba(MnO_4)_2$ in neutral and slightly alk. solns. and with CrO_3 in 90% aq. $AcOH$ soln., there is evidence of a progressive degradation of the fibers and CO_2 is one of the chief products of oxidation. From ash, Cu no., alkali soly., furfural and Lefèvre CO_2 detns., the cotton oxidized in acid soln. contains a larger amt. of oxidized cellulose on the fiber than in neutral soln. Soly. of oxidized cellulose in alkali is regarded as due not only to salt formation and aldehydic reactions but also to soln. of a portion of the unattacked, though probably depolymerized, cellulose. The viscosity of $Cu-NH_4$ hydroxide solns. of oxidized cellulose is much lower than of the original cotton, even when the min. amt. of oxidant was used. Acetylation tests showed that the av. no. of OH groups decreased from 3 to nearly 2. Oxidation of cellulose, in general, is accelerated by alkalis and retarded by dil. acids, and also is dependent on other exptl. conditions. Oxidized cellulose is regarded as a mixt. of a large amt. of unattacked, but partly depolymerized, cellulose with small quantities of complex oxidation products, aldehydic and acidic in nature.

J. L. PARSONS

Determination of α -cellulose. C. G. SCHWALBE. *Papierfabr.* 23, Tech.-Wiss. Teil, 177-80 (1925); cf. C. A. 19, 170, 2127.—Report of a comparative investigation of the Jentgen, Waentig and Fiber Analysis Committee (German) methods for the detn. of α -cellulose in wood pulps. A recommended sampling procedure is to cut the pulp strips into small pieces. Disintegration of the sample in an Fe grinding mill increases the ash content in Fe by as much as 9.3%. Rased pulp contains fibrous particles which are strongly attacked by the alkali. Comparative α -cellulose detns. gave the following results: by the Jentgen method, 86.4-88.2%; by the Waentig method, 83.5-87.0%; and by the Committee procedure, 84.9-87.0%. The Waentig method was considered unsatisfactory. Time, temp. and the method of stirring are the most important factors in the detn.

The manufacture of vulcanized fiber products. F. HUTH. *Papierfabr.* 23, Tech.-Wiss. Teil, 621-3 (1925).—A general discussion. J. L. PARSONS

Swelling and adsorption of cotton and wood pulp fibers. C. G. SCHWALBE AND G. A. FELDTMANN. *Papierfabr.* 23, Tech.-Wiss. Teil, 589-95 (1925).—A simple method for detg. the absorption quality of a pulp is to expose weighed strips of air-dry sample, 4 by 8 cm., to the action of a liquid for 4 hrs. at room temp. The pulp is then drained for 120 sec. and weighed. By this method there were practically no differences in the absorption of water and of a 1% AcOH soln. by various pulps. Water absorption of bleached pulp is less than that of unbleached pulp. Swelling and adsorption of fibers are closely related. The latter is easily detd. by ascertaining the quantity of Fe_2O_3 retained by the fibers after exposing the pulp to a $\text{Fe}(\text{OAc})_3$ soln. for 1 hr. with agitation. The no. g. Fe_2O_3 held by 100 g. ash- and moisture-free fibers is termed the Fe_2O_3 no. Detns. of water absorption and the Fe_2O_3 no., in addn. to the usual chem. analysis, are valuable quality tests for wood pulps. The researches of S. and Teschner (C. A. 19, 3017) are discussed. The amts. of Al_2O_3 and Fe_2O_3 retained by the fibers are proportionately the same. Unbleached Mitscherlich pulps show greater absorption than other pulps. J. L. PARSONS

The reducing power of waste sulfite liquor and its use in dyeing and bleaching. M. G. KOTIBHASIKER. *J. Soc. Dyers Colourists* 41, 361-2 (1925).—The reducing power of waste sulfite liquor was measured by Fehling soln.; it was found that 17.66 cc. of the liquor was equiv. to 1 g. of $\text{Na}_2\text{S}_2\text{O}_4$. Lab. expts. were made to test the action of the liquor as a reducer in indigo dyeing and indigo stripping. The work is in progress. L. W. RIGGS

Production of sulfite cellulose from *Pinus maritima* in France. ANON. *Papir-Journalen* 13, 153-4 (1925).—The usual sulfite cellulose app. was used. Fresh wood 4-6 in. and with 18-23% moisture was digested for 15 hrs. The yield of cellulose was 35.7%. W. SEGERBLÖM

Ventilation in paper and cellulose plants in connection with recovery of heat. H. ERIKSSON. *Svensk Pappers-Tid.* 28, 391-3, 450-5 (1925).—Tables, diagrams and graphs give further data similar to items mentioned in C. A. 19, 2745. W. SEGERBLÖM

Ionic reactions in the sulfite pulp cooking process. E. ØMAN. *Svensk Pappers-Tid.* 28, 81-4, 106-10 (1925); *Papierfabr.* 23, Tech.-Wiss. Teil, 445-8, 483-6, 510-3, cf. C. A. 19, 2743. J. L. PARSONS

The use of chlorine in the production of bleaching liquors. B. SMÄRT. *Svensk Pappers-Tid.* 27, 447 (1924).—Of the Cl used in bleaching pulp 80% is shipped as liquid Cl and not as CaOCl_2 . Prepn. of liquid Cl is described. Freshly burnt lime is slaked, strained and pumped into absorption chambers supplied with stirrers and special inlets for Cl. The temp. is regulated to prevent chlorate formation. The resulting Ca hypochlorite soln. contg. 20-30 g. Cl per l. is run into settling tanks. The clear soln. is dild. to hold 15 g. Cl per l. (cf. C. A. 19, 2129). W. SEGERBLÖM

Sizing with hard water. J. CHINTSCHIN. *Zellstoff u. Papier* 5, 299-300 (1925).—Polemical with Lorenz (C. A. 19, 2129). Coagulation of rosin size is possible with a hard water when the paper stock is sufficiently highly dild. Sizing expts. should be carried out under mill conditions to det. the best practice to follow with hard water. The size concn., in general, should be increased. RUDOLF LORENZ. *Ibid.* 300-3. —A reply to Chintschin's criticism. Pptn. of rosin size with hard water is independent of the size dild. but is influenced by the compds. in the water. Mg salts are more effective precipitants than Ca salts. The more concd. the rosin emulsion, the more rapid is the pptn. with hard waters. For the protection of size dispersions the use of protective colloids is recommended (cf. C. A. 19, 3017). J. L. PARSONS

Pulp produced from Bordeaux pine by the Chevalier-Girard process. A. RETTORI. *Papeterie* **47**, 798, 801 (1925).—Results of analysis of pulp produced by the Chevalier-Girard process, the details of which are not given (Fr. pat. 568,630—the chipped wood is treated for 2-6 hrs. at 90-100° with an alk. soln. to remove the resin, drained, washed and treated by one of the usual processes) show it to be equal to the best grades of wood pulp produced by the ordinary soda and sulfite processes. A. P.-C.

Semi-cellulose and semi-chemical pulping. J. D. RUE. *Paper Trade J.* **81**, No. 16, 57-9 (1925).—A review of the literature and patents on processes for the treatment of wood preliminary to grinding (or mech. disintegration by other means than the ordinary grinder), so as to increase at low cost the strength and quality of the product without serious loss of yield. Steaming apparently is the only process used commercially at present for the purpose.

A. PAPINEAU-COUTURE

New developments in refining and finishing of paper pulp. K. A. PELIKAN. *Paper Trade J.* **81**, No. 17, 52-4 (1925); *Pulp Paper Mag. Can.* **23**, 1387-9 (1925).—Waste paper can be cheaply and efficiently de-inked by passing through a Hurrell homogenizer together with a suitable "solving agent," the cost and efficiency of the treatment both being increased by increasing the diln. of the pulp or the amt. of solvent. By passing pulp through the mill under certain conditions (not described) the mill does not hurt the fibers appreciably, but thoroughly seps them from one another. Colloidal rosin suspensions can be made without the use of alkali by passing through the homogenizer together with a suitable filler to prevent subsequent coagulation of the rosin particles. The "filler" may consist of montan wax, fibers (pulp), clay, satin white, blanc fixe, etc., $Mg(OH)_2$, $Al(OH)_3$, glue, casein, viscose. The $Mg(OH)_2$ or $Al(OH)_3$ can be either left in the pulp as a filler, or removed by means of acid. Paper-making fillers or dyestuffs can be reduced to an impalpable state of fineness by putting through the homogenizer, and the resulting material gives a better yield and better and more homogeneous appearance to the paper.

The manufacture of coating stock. E. ARNOULD. *L'industrie papetière* **4**, 266, 268 (1925).—Practical hints on properties, furnishes and operating conditions.

A. PAPINEAU-COUTURE

Some properties of paper. P. M. HOFFMAN JACOBSEN. *Paper* **28**, 895-900 (1925); *Paper Trade J.* **81**, No. 21, 49-51 (1925).—Breaking length (tensile strength), "zero-breaking-length," fiber breaking length, adhesion and bulk are defined. The importance of testing conditions, and more particularly of tension in detg. folding resistance, is briefly discussed (cf. *C. A.* **19**, 174).

A. PAPINEAU-COUTURE

Woods from French West Africa ("Emien," *Alstonia congensis*, Engl.). F. HEIM, M. CERCELET, J. MAHEU, G. S. DAGAND AND R. HEIM DE BALSAC. *Bull. agence gén. colonies* **17**, 1377 (1924); *Bull. Imp. Inst.* **23**, 367-8 (1925).—A sample of "Emien" from Ivory Coast, contg. 8.25% H_2O , showed (on dry basis): ash 0.91, fats and waxes 0.63, cellulose 64.3, lignin 34.16%. Cooking 8 hrs. under a pressure of 3 kg. with a 5.5% NaOH soln. gave a brownish yellow pulp, which bleached white with av. facility, yielding 33% (on dry basis) of bleached pulp. The pulp consists almost entirely of narrow-ended, cylindrical fibers, with very thin walls and very wide lumen, 1.0-1.5 mm. long (av. 1.2 mm.), 0.025-0.035 mm. (av. 0.030 mm.) in diam., and with a felting power (diam.: length) of 0.025. The pulp gives paper of similar quality to ordinary wood pulp papers (cf. *C. A.* **19**, 1947).

A. PAPINEAU-COUTURE

Sorghum from Madagascar. R. HEIM DE BALSAC, J. MAHEU AND M. CERCELET. *Bull. agence gén. colonies* **18**, 360 (1925); *Bull. Imp. Inst.* **34**, 466 (1925).—Fragments of stalks received under the name of "Bakaka," a form of *Sorghum vulgare*, Pers., contg. 9.59% H_2O , showed (on dry basis): ash 6.22, cellulose 82.83, lignin 10.05%. Cooking 7 hrs. under pressure (not given) with a 5% NaOH soln. gave a yellowish brown, very easy-bleaching pulp. The yield of bleached pulp was 37%. It is composed of fibers, fragments of vessels, and a rather large proportion of cellular matter. The felting power was 0.005. Paper made from the bleached pulp was dull white, soft to the

touch, and had a fair rattle; in general it was of good quality but a little lacking in suppleness.

(Paper making qualities of) creepers from Indo-China. F. HEIM AND M. CÉRCELET *Bull. agence gén. colonies* **17**, 1609(1924) *Bull. Imp. Inst.* **23**, 366-7(1925).—Sixteen kinds of creepers, which have not been botanically identified and are referred to under their native names, can be converted into pulp by similar treatment. In each case the samples were cut into pieces 3-4 cm. long and 3-5 mm. thick, and were digested with a 3-4% NaOH soln. for 3.5-4 hrs. Bleaching was effected with av. facility and yielded 20-32% (37% in one case) of bleached pulp. The av. yield from the whole series was 28%. The paper made from the pulp was generally of fairly good quality. Some difficulty might be experienced in sepp. the different species of creepers, but there appears to be no doubt that good results would be obtained by treating them in admixt.

A new method for determining the strength of chemical pulp. P. M. HOFFMAN JACOBSEN. *Papier* **28**, 877-80(1925); *Paper Trade J.* **81**, No. 22, 52-3(1925).—J. shows that the tensile strength of paper can be found from that of the pulp from $r = R \cdot \gamma \cdot a$, in which r is the breaking length of the paper, R is the "zero-breaking-length" of the unbeaten pulp, γ is the increase in R obtained by beating for the given grade of paper (to be detd. exptly. under mill conditions), and a is the adhesion (ratio of ordinary to "zero" breaking length, approx. const. for a given grade under given mill conditions)(cf. *C. A.* **19**, 2129).

Determination of the acidity of paper. S. KOHLER AND G. HALL. *Paper Ind.* **7**, 1059-63(1925).—The acidity of engine-sized papers is mainly due to the rosin precipitant (usually $Al_2(SO_4)_3$) ("internal" acidity); that of tub-sized papers to the $Al_2(SO_4)_3$ added to preserve the glue ("external" acidity). The latter is almost harmless as regards the permanence or durability of the paper, while the former may affect durability seriously. To det. total (both "internal" and "external") acidity, grind the sample in a suitable app. (e. g., a Koerner leather grinder), to 5 g. in a 500-cc. Erlenmeyer flask add 250 cc. of boiling water in small portions with vigorous shaking between addns (see that the paper is properly soaked), heat 1 hr. on a steam bath with an air reflux condenser, drain off on a Buchner funnel (with a strong suction), rinse with 10 cc. cold water, transfer the fibers back to the flask and repeat the extn. twice. Cool the exts. to room temp. and titrate separately with 0.01N NaOH, using phenolphthalein as indicator. The "acidity no." is the total no. of cc. of 0.01 N NaOH required to neutralize the first 3 exts., calcd. per 10 g. of oven-dry paper. To det. "external" acidity, use the following modification of Vandeveld's method (*Revue des Bibliothèques et Archives de Belgique* 1906, Pt. 4, p. 77): cut 10 g. into small pieces, ext. by shaking continually for 2 min. with 100 cc. of cold distd. water, draw off on a Buchner funnel without washing, and titrate as before. "Internal" acidity is the difference between total and "external" acidities. Titration with iodeosin indicator (see Richter, *C. A.* **6**, 2524; Quist, *C. A.* **14**, 344) gave much lower results, but the ratio of the results obtained with the 2 indicators was practically const. Iodeosin titrations are much more tedious.

The technic of the use of rosin in paper making. A. THIRIET AND P. DELCROIX. *Chimie et Industrie, Special No.*, 508-12(Sept., 1925); cf. *C. A.* **18**, 3718. Free rosin is the active sizing agent, and the rosin is made into soap so as to obtain the required degree of subdivision. Use of an acid size contg. more or less free rosin is of advantage only insofar as it reduces alkali consumption, and it does not give any better results than neutral or alk. size, provided the stock has the right p_H when it reaches the paper machine. This should be 4.5-5.0. This is readily controlled by means of methyl red and of Na alizarinsulfonate, proper sizing conditions obtaining when the back water from the paper machine gives the same color with both indicators. A continuous and recording control method could be worked out by means of the cond. of the back water, the excess of alum being the main factor affecting the cond.; but details would have to be worked out in each mill according to local conditions. Graphs are given by means of which the amt. of H_2SO_4 required to replace a given proportion of alum can be calcd.

Demonstration of the use of glue in coated paper. ANON. *Paper Mill* **49**, No. 43, 16, 18, 37, 38(1925).—A demonstration of the use of glue in coated paper was given at the Paper Section, Bur. of Standards, and at the Govt. Printing Office, Washington. Results of practical coating and printing tests showed that: (1) with proper selection of the glue and adaptations to local conditions and product requirements, the use of glue in coating paper requires little change in equipment and involves little change in operating technic from procedure with casein; (2) the choice of various types of glue

offers a considerable latitude within which local conditions may be met; and (3) the use of glue-bound coated paper offers no new difficulties to the printer and engraver as regards printing processes other than lithographic color work and possibly offset processes.

A. PAPINEAU-COUTURE

Determination of the specific gravity of paper-making fillers. J. R. *Papeterie* 47, 905-9(1925).—The method uses Regnault's volumenometer and is based on Mariotte's law. It consists essentially in placing a weighed amt. of the material in a flask of known vol. connected to a Hg manometer. By addn. or withdrawal of Hg from the manometer the vol. is changed by a known amt.; and by reading the resultant change in pressure the actual vol. of gas in the app. contg. the filler can be calcd., thus giving the vol. actually occupied by the powder.

A. PAPINEAU-COUTURE

Manufacturing of pulp and paper in 1925. W. G. MACNAUGHTON. *Paper Trade J.* 81, No. 18, 35-41(1925).—Discussion of the present status and tendencies of pulp and paper mfg. along mech. and chem. engineering lines, mainly as regards the use of wood as the chief primary raw material.

A. PAPINEAU-COUTURE

Theory and practice of rosin sizing. RUDOLF LORENZ. *Wochbl. Papierfabr.* 56, 962-7, 1027-30, 1090 3, 1214-6(1925); cf. *C. A.* 19, 2129, 2564. —The concluding articles of a series in which recent developments in rosin sizing are discussed from a colloid-chem. standpoint. Concerning the pptn. of rosin size in the beater, the following conclusions are reached: (1) The Al ion exerts a coagulating effect over all ranges of concns.; (2) with a high concn. of rosin, especially with a large amt. of alkali, a portion of the former is carried down with the insol. $\text{Al}(\text{OH})_3$ formed in the beater; and (3) the colloidal coagulation of a rosin- $\text{Al}(\text{OH})_3$ adsorption compound depends upon the relative concns. of the rosin and $\text{Al}(\text{OH})_3$. There are yet many difficulties in sizing with rosin prepd. in a mech. way, as by means of the colloid mill. J. L. PARSONS

French colonial cellulosic fibers. A. THIRIET. *Chimie et industrie, Special No.*, 498-507(Sept., 1925).—A review of the paper making qualities of the more important French colonial fibers.

A. PAPINEAU-COUTURE

Bald-cypress (*Taxodium distichum*) pulp. I. VIDAL. *Papier* 28, 985-8(1925).—Results are given of a detailed micrographic examn. of the sample included in Surface's "Paper pulps from various forest woods" (*C. A.* 6, 3516). The sample in question was very noticeably undercooked and contained many shives and incompletely sepd. fiber bundles. A sample prepd. in the lab. from a tree grown at Grenoble (France) seemed to be of better quality and appeared noticeably stronger. V. concludes that, though not as good as spruce pulp, bald-cypress pulp is of some value and could doubtless be used instead of spruce in many cases.

A. PAPINEAU-COUTURE

Physico-chemical study of cellulosic fibers. ROGER BOUSSU. *Papyrus* 6, 495-7(1925).—The colloidal properties of cellulose and its chief derivs. (hydracellulose, hydrocellulose and oxycellulose) are briefly reviewed, and the phenomena of beating, sizing and loading are explained in the light of these properties.

A. P.-C.

Khanbaligh and other ancient Asiatic papers. R. BOUVIER AND L. VIDAL. *Mon papeterie française* 56, 467-70(1925).—A description of Khanbaligh paper, an exceptionally high-grade, ancient, Persian paper of Chinese manuf., of 2 samples of Chinese papers of the 15th and 17th centuries, resp., of 2 samples of Persian papers of the 10th and 12th centuries, resp., of a Syrian paper of the 12th century, and of a Turkestan paper of the 10th century, all of which are taken from old dated manuscripts.

A. PAPINEAU-COUTURE

The impregnation of pasteboard. J. SOUDIER. *Caoutchouc & gutta-percha* 22, 12862-3(1925).—A brief description of present developments in impregnating cardboard with viscose and drying oils.

C. C. DAVIS

Electric drive in a modern paper mill. O. C. CORDES AND B. L. KERNS. *Elect. World* 86, 1143-7(1925).

C. G. F.

The manufacture of pulp by the chlorination process. U. POMILJO. *Wochbl. Papierfabr.* 56, 1115-21(1925).—Description of the Pomilio Cl process for the manuf. of chem. pulp from straw, esparto, etc. In spite of the large no. of chem. and mech. operations (12 in all) the process is easily controlled and requires a comparatively small amt. of fuel. The treatment varies with the kind of fibrous raw material and the cellulose produced is of a very high quality. The pulp yield from esparto was 38.6-42.0%; from cereal straw, 38.5-42.0%; and from rice straw, 31.7-38.9%. J. L. PARSONS

The solubility of sulfur dioxide in calcium bisulfite solutions up to 100° and certain practical considerations. JARL ENCKELL. *Pappers och Trävarutidskrift för Finland* No. 4, 93-9(1925); *Papierfabr.* 23, Tech.-Wiss. Teil, 633-6. —The solubilities of SO_2 in water, in $\text{Ca}(\text{HSO}_3)_2$ solns. of different concns., in 6.8% H_2SO_4 soln., and in 7.5% Na_2SO_4 soln. are given over the range 40-90°, at 10° intervals and 1 atm. pressure.

Its soly. is somewhat less in an acid or salt soln. Graphs are shown indicating the relations between the concn. of free SO_2 in sulfite cooking acid and the gas pressure above the soln., and also between gaseous SO_2 , water vapor and air at different temps. and acid concns. at 1 atm. pressure. To diminish losses of SO_2 in waste gases, the latter should be introduced into the cooking liquor through an injector. Filling a pulp digester at the bottom with cooking acid contributes to SO_2 economy. Steaming the chips brings the SO_2 loss to a min.

Filter paper. ANON. *Papierfabr.* 23, Tech.-Wiss. Teil, 639-41(1925).—A general discussion.

Evaporation of waste sulfite liquor. F. KOENIG. *Papierfabr.* 23, Tech.-Wiss. Teil, 544-5(1925).—Waste sulfite liquor, before or after neutralization and after being heated by waste heat from the mill, is evapd. by exposing a large surface to the atm. and sun, as in a salt works.

Blotting paper and cardboard. H. POSTL. *Papierfabr.* 23, Tech.-Wiss. Teil, 578-80(1925).—A general discussion of the raw material for blotting-paper manuf. and its prepn. for the machine. Fine blotting paper is made from cotton cuttings, a good blotting paper is made from cotton rags and aspen wood pulp and a cheap paper has the following compn.: 30% coniferous wood pulp, 40% aspen wood pulp, and 30% clay. Its testing is briefly described.

New methods for the regeneration of alkali from black liquors. E. HAGGLUND. *Papierfabr.* 23, Tech.-Wiss. Teil, 493-9(1925).—Decarbonization of black liquors from alk. wood digestion processes is effected by heating the filtered liquor in an autoclave to 350°. The org. matter is converted to gases (mainly H_2 and CH_4), MeOH, tar, C and AcONa. Increase in alky. of the liquor decreases the pitch and MeOH yields, while the vol. of gases evolved is greater. The following by-products were obtained from a metric ton of kraft pulp from pine wood: 510 kg. tar and C, 130 cu. m. gas, 325 kg. AcONa crystals, and 55 kg. MeOH. From straw, calcd. on a ton of pulp, 375 kg. AcONa and 26 kg. MeOH were obtained, and from birch wood pulp, 500 kg. AcONa and 36 kg. MeOH. The calorific value of the tar, C and gases is sufficient to furnish heat and steam for the alkali regeneration, the cooking and drying of the pulp and other purposes. Black liquor from the sulfate process yields by-products contg. S.

Bag papers. W. ROTH. *Papierfabr.* 23, Tech.-Wiss. Teil, 529-31(1925).—An exptl. investigation of bag papers showed that paper made from soda pulp is preferable for filling with hot material, such as cement, etc., because of its ability to regain moisture and strength. The more viscous a pulp stock becomes, the less permeable is the resulting paper to air and the less suitable for bag paper. Paper having a tearing length over 5000 m. and a stretch over 3% is unsuitable for bag manuf. The air no. is defined as the time required for 1 l. air under a certain pressure to pass through a certain area of paper, and is a test used in evaluating papers made from soda and sulfite pulps for bag manuf.

Cymene. F. KOENIG. *Papierfabr.* 23, Tech.-Wiss. Teil, 501-2(1925).—Of the 8-12 kg. cymene formed in the manuf. of a ton of sulfite pulp, only 0.1 is obtained in the crude condition. SO_2 is removed from the cymene mixt. by shaking with NaHCO_3 soln. and after several hrs. the oil seps. from the water and can be siphoned off. The crude cymene was distd. and the distillate redistd. over Na to 200°. Fractionation was carried out under reduced pressure at 240° and 60 mm. The first fraction, yield 38.6% and distg. at 174-8° and 740 mm., consisted mostly of *p*-cymene. Six fractions were made in all; the residue was a brown resin, amounting to 25.9% of the cymene used. Crude cymene was also neutralized and distd. with steam, yielding 47.2% distillate (sp. gr. 0.867, 20°), and 52.8% residue (sp. gr. 0.99). Fractionation of the distillate gave a 76.6% yield cymene, b. 173-7.5°.

Strength tests on pulps. K. RIETH. *Papierfabr.* 23, Tech.-Wiss. Teil, 525-9(1925).—Strength tests on pulps showed that the max. tearing length was obtained when the stock was parchementized. The expts. are described in detail. The CI figure of the pulp decreases with an increase in strength.

Investigation on the strength of fine paper with special reference to paper of the Swedish government. II. S. KOHLER AND G. HALL. *Svensk Pappers-Tid.* 28, 333-9, 358-63, 421-5, 446-9(1925); cf. C. A. 19, 2745.—Surface-sized paper resists molds and bacteria better than rosin-sized paper. Addn. of $\text{Al}_2(\text{SO}_4)_3$ or NaF to animal size increases this resistance. Two percent NaF is equiv. to 10% $\text{Al}_2(\text{SO}_4)_3$, and obviates an acid condition in the paper. $\text{Al}_2(\text{SO}_4)_3$ in the usual amts. in surface-sized paper does not markedly affect the strength. Corresponding tests with NaF were not tried.

W. SEGERBLOM

The removal of printer's ink from old paper. E. BERL AND W. PFANNMÜLLER. *Z. angew. Chem.* **39**, 887-9(1925).—Removal of printer's ink from old papers was best accomplished by a short preliminary cooking at low temp. with $N/20-N/60$ NaOH, followed by agitation of the stock with tetralin, which dissolves the binding material in the ink and holds the lampblack in suspension. The org. solvent, carrying the removed ink, is sepd. from the stock by flotation from water, the fibers remaining in suspension in the water. W. H. SWANSON

Grease-proof and sulfite paper. ANON. *Svensk Pappers-Tid.* **28**, 386-7(1925).—An investigation made by the Government Testing Institute, Stockholm, to det. the difference in compn. and general character of grease-proof and sulfite paper. One grease-proof and 3 sulfite papers were tested. The different qualities of paper made from sulfite cellulose do not appreciably differ in regard to sizing. The grease-proof differs considerably from the sulfite paper in regard to the microscopic appearance of the fibers, transparency, water absorption, and grease-proofness. The grease-proof paper, being manufd. from a more drastically beaten and hydrated pulp, allows 25-50% more light to pass through it, absorbs less water and is considerably more grease-proof than the sulfite samples. Printed in English. W. SEGERBLÖM

Plant control. E. MATHESON. *Papir-Journalen* **13**, 205-15(1925).—Various aspects of modern plant control in the paper industry are collected. Their relations to each other are discussed on an economic basis. Tables compare the detailed items of raw material, fabrication and administration of paper, sulfite and pulp. Machine production and efficiency records also are given. Some of the tables are in English. W. SEGERBLÖM

Influence of moisture of air on determination of moisture in paper. R. KARLBERG. *Svensk Pappers-Tid* **28**, 306-7, 363-5, 388-91(1925).—Newspaper in single sheets having a lower moisture content than surrounding air rapidly takes up moisture. Absolutely dry paper in 8 min. took up 6% and 16% moisture with a relative air moisture of 40% and 90%, resp. Samples for moisture content must be taken with this in mind. Closely packed paper and paper in rolls do not take on moisture so rapidly. Absorption data are tabulated and absorption curves given. W. SEGERBLÖM

Insulation material from impregnated hard paper. K. J. BRIQUER. *Kunststoffe* **15**, 17-9, 31-5(1925).—Discusses the impregnation of paper with bakelite and the forming of tubes, etc., from it. C. J. WEST

Rendering paper impermeable to water. KARL MICKSCH. *Kunststoffe* **14**, 52-4(1924).—Review of methods. C. J. WEST

Paraffin paper. KARL MICKSCH. *Kunststoffe* **14**, 122-3(1924).—General discussion of its manufacture. C. J. WEST

Paper and cellulose investigations conducted in Laboratory D at the Technical High School in Norway. S. SCHMIDT-NIELSEN. *Papir-Journalen* **13**, 250(1925).—A lecture on the retention of paper fillers by pulp fiber. S. considers retention as a filtering process, modified by various adsorption processes. In unsized paper, the amt. of filler retained increases with the size of the granules within certain limits. On the other hand, the possibility of adsorption is increased with a decrease in the size of the granules. *Ibid* 267. A report on expts. showing that sulfite solns. of relatively low % of CaO and high % of SO₂ had the highest solvent effect on cellulose and in-crustants in wood shavings. The solvent action increased rapidly near 125°, but boiling above this temp. (125-140°) caused a darkening of the fiber mass. E. O. E.

Toxicity of solvents for rubber, resins and cellulose esters (KOHN-ABREST) **30**. The conversion of wood cellulose into sugar and alcohol (FOULON) **16**. Distribution of lignin in wood (RITTER) **11D**. Purification of waste waters from cellulose factories by fish ponds (SELTER, HILGERS) **14**. Modified casein [for sizing paper] (U. S. pat. 1,551,471) **18**. Preheating and spray desiccation of waste sulfite liquor by combustion gases (U. S. pat. 1,558,022) **13**.

Nitrating cellulose. G. JUER. U. S. 1,562,093, Nov. 17. Cellulose and nitrating acids are thoroughly mixed in a mixing pot so as to effect a partial nitration of the cellulose, and the mixed materials are then charged into a rotatable cylinder and tumbled in the latter to complete the nitration.

Nitrocellulose solvent from wood-tar oil. A. E. MAZE. U. S. 1,558,446, Oct. 20. A wood-tar distillate b. up to 130° is agitated with bleaching powder to obtain a product of improved odor and good solvent properties, adapted for use as a solvent for nitrocellulose, etc.

Molded articles from nitrocellulose and furfural. C. ELLIS. U. S. 1,558,442, Oct. 20. Nitrocellulose is dissolved in furfural and the acidulated mixt. is allowed to harden in molds or spread to form molded articles or films.

Water- and grease-proof paper. L. KIRSCHBRAUN. U. S. 1,561,728, Nov. 17. A fibrous web is treated with bituminous material and with a product formed from waste sulfite liquor and formaldehyde.

Stencil sheet. R. LANT. U. S. 1,561,865, Nov. 17. Sheets adapted for stencilization by pressure comprise a base of open porous material such as Japanese paper with a type-impressible coating including nitrocellulose or similar cellulose derivs., castor oil and tallow.

• **Stencil sheet.** J. D. GRANGE. U. S. 1,562,228, Nov. 17. A sheet of Japanese Yoshino paper or similar fibrous material is impregnated with gelatin or other protein, an Al salt such as $\text{Al}_2(\text{SO}_4)_3$ and HOAc or other material which retards the hardening effect of the Al salt, together with a "tempering agent" such as glycerol and sugar, a coloring agent and H_2O .

Evaporating waste sulfite liquor or other liquids. G. BOJNER. U. S. 1,561,636, Nov. 17. Combustion gases are passed through a rotating heater immersed in the liquid to be evapd. and the heater is rotated with sufficient speed substantially to avoid incrustation.

Control of bisulfite pulp cooking. J. E. FLEURY. U. S. 1,562,217, Nov. 17. A sample of liquor is drawn from the digester in operation, treated with NH_4OH or other alk. hydroxide and an alc., filtered, dild. and compared in a colorimeter with standard samples corresponding to certain percentages of strength and bleach of finished pulp.

Rosin from pulp mill black liquor. F. E. GREENWOOD. U. S. 1,560,420, Nov. 3. Resinous components of black liquor are treated with a solvent or emulsifying liquid e. g., gasoline or naphtha, and an acid such as H_2SO_4 is added which will liberate resinous substances so that they may be taken up by the solvent. A second solvent, immiscible with the first solvent e. g., EtOH or MeOH , is used for selective sepn. of the rosin from the soln. in which it is first obtained.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Richard Escales. ANON. *Kunststoffe* 14, 145-6(1924).—Obituary. A list of his publications is given.

Sugar-dust explosions. VOJTECH SANDTNER. *Z. Zuckerind. czechoslovak* Ref. 50, 33-8, 41-5(1925).—Mainly a review of the work of Beyersdorfer. Cf. C. A. 15, 1996; 16, 1021; 17, 1144, 1551, 2192, 2785, 3608.

Mine dust. Its sampling and treatment as carried out at the Cannock Chase colliery. M. J. FOGGO. *Colliery Guardian* 130, 1047(1925).—In wide experience with the sampling of mine dust, 1.2% needed treatment with non-combustible dust, viz. with gypsum. This ratio is based on the practice of treating with gypsum all roadways or zones having 40% or more of combustible in the dust. The latter amt. is chosen because it has been found with some dusts that it is possible to explode a 50/50 mixt. The methods of sampling and treating and the keeping of records are described in detail.

C. C. DAVIS

The ignition of gases. A. C. G. EGERTON. *Colliery Guardian* 130, 556(1925). The time for detonation of an explosive mixt. to occur varies with the particular gas present, being longest delayed with N, less so with A and occurring soonest with O.

C. C. DAVIS

The ignition of gases. H. B. DIXON. *Colliery Guardian* 130, 555-6(1925). A crit. discussion of the ignition of gases under various conditions, covering work from that of Bunsen and LeChatelier to the most recent developments.

C. C. DAVIS

The ignition of gases. O. C. DE C. ELLIS. *Colliery Guardian* 130, 556(1925). A discussion of the principles and characteristics of the propagation of flame in a closed vessel with and without an opening. When CO or other combustible gas is exploded in O the flame is followed by a glow beginning near the point of ignition. When the combustible mixt. is satd. with H_2O vapor at 45° the glow is still marked but is of far less intensity and duration, suggesting that burning takes place after the flame passes through the mixt. Certain radiations which are found after passage of the flame affect a photographic plate, and it is possible that they represent a residual combustion of gas which has escaped the flame.

C. C. DAVIS

The ignition of gases. W. T. DAVID. *Colliery Guardian* 130, 556.—Expts. are described in which *spontaneous ignition temps. of inflammable gaseous mixts.* were detd. by means of adiabatic compression produced by the flow of compressed air in a tube contg. the mixt. Under these conditions the spontaneous ignition temp. varies with the pressure, this temp. decreasing with increase of pressure in mixts. of CH_4 and O. Further expts. on the *rate of combustion of inflammable mixts.* in a closed system showed that the introduction of infra-red radiation increases the speed of combustion provided that N is present and that the radiation is of such a nature that it is absorbed by the gases. Thus the rate of combustion of CO and O with N present is increased by 4.4μ rays and that of CH_4 and O with N by 3.2μ rays. Since H has no absorption bands, radiation does not accelerate the combustion of H and air. No such increase in the rate of combustion occurs when the N is replaced by O, A or CO_2 . The expts. suggest a temporary association during explosion of N and the combustible gas which is inhibited by the radiation. The rate of combustion of CO and O with N is much greater when the interior of the container is polished (Ag-plated) than when it is black. C. C. D.

The ignition of gases. E. K. RIDEAL. *Colliery Guardian* 130, 556(1925).—The acceleration of combustion in the presence of N described by David (cf. preceding abstr.) may be due in part to the fact that N is activated by the absorption of radiation and acts as a reservoir of energy. C. C. DAVIS

Explosibility of coal and other dusts in a laboratory steel dust gallery. V. C. ALLISON. *Colliery Guardian* 130, 495-6(1925).—A lab. app. for the study of the explosibility of various combustible dusts is described. Data were obtained which show graphically the *length of flame of explosive mixts. as a function of the concn. of the dust in the air.* The limits of explosibility for mixts. of combustible and inert dust also were studied. With increasing concn. the explosibility of a dust passes through a max. and then decreases, but this is not true of a mixt. of coarse and fine mine dust where the coarse dust is less inflammable and there is only a partial initial combustion. Furthermore 1 dust may be more explosive than another at low concns., and yet the explosibility of the second increases so rapidly at higher concns. that the order of explosibility of the 2 dusts is reversed. A third dust may be more explosive than either at low concns. and less so at higher concns. Thus S dust, though more difficult to ignite at low concns. than starch, sugar, corn, wheat, coal or Al, ranked next to Al at higher concns. The explosibility comprises in general 3 factors: the *initial explosibility*, the *rate of increase of explosibility with increase in concn.* and the *max. explosibility.* There is no necessary relation between the explosibility and the rate of combustion. The explosibility may further be divided into 2 factors, the explosibility of the dust *per se* and the explosibility of that part of the dust rendered volatile by the explosion flame. Combustible volatile is not necessary in a dust to render the latter explosive, though it does increase the explosibility. Any dust not already in its most highly oxidized condition may explode if in sufficiently fine condition. Moisture is about 2.4 times as effective as ash in reducing the explosibility, a ratio which is close to that of their heat capacities. The limiting % of inert dust (*I*) to prevent explosion in a mixt. of inert dust and combustible dust can be expressed by the relation $I = 46 + 79 [\text{volatile}/(\text{volatile} + \text{fixed C})] - 1.7\text{H}_2\text{O} - 0.5 \text{ash} - 1.5\text{CO}_2 + 2\text{CH}_4$, where all components are expressed in %. This is accurate to ± 4 parts of rock dust. If *I* is below 60, subtract 5, if over 60, add 5. For coarse mixed mine dust in not too large amt., 17 parts of rock dust should be subtracted from *I*. The term CO_2 can be replaced by $7.5 \times \text{O deficiency}$ when an inert gas is used as the explosion preventive. C. C. D.

Fire hazards of static electricity. R. M. CLARK. *Ind. Eng. Chem.* 17, 1127-9 (1925).—Fire hazards in cleaning processes of various types, in cotton ginning, agitation of org. liquids, etc., are discussed with examples, and the necessity of properly interconnecting and grounding all parts is emphasized. Oil films in bearings may give sufficient insulation to permit accumulation of static in rotating parts despite thorough grounding of the body of the machine, and hence brushes should be used properly to ground agitators, etc. WM. B. PLUMMER

Heat stability tests of guncotton. MARCEL LEMIRE. *Bull. soc. ind. Rouen* 53, 292-6(1925).—Brief description of the Abel, "110" and Bergmann stability tests. The latter is the most severe. Guncotton washed with distd. H_2O gave satisfactory results with the "110" test, but almost invariably exploded in the Bergmann test, while guncotton boiled with hard water followed by washing with Na_2CO_3 soln. and finally by working in the presence of CaCO_3 gave a satisfactory Bergmann test (cf. Bréguet and Caille, C. A. 18, 3715). A. PAPINEAU-COUTURE

The liquid-oxygen plant of the Real del Monte Co. J. MARTINEZ. *Bol. minerio Mexico* 20, 105-19(1925).—Actual experience showed that 1 kg. of 40% dynamite =

2.1 kg. of liquid O or 0.87 kg. of liquid-O explosive. To obtain a useful kg. of liquid O it was necessary to produce 3.36 kg., the difference being evapn. losses. These are higher than in Germany because local labor is less efficient. Whenever the price of 40% dynamite is above 41.17 centimos per kg. it is economical to use liquid O. Its advantages of safety, absence of CO when properly shot and beneficial effect on mine air are reviewed. Only a large concern can manufacture it economically. E. M. SYMMES

The Fort Worth Imhoff tank accident (THACKWELL, JONES) (CAMP, LEWIS) 14.
Fort Worth Imhoff tank explosion recalls one in S. Carolina (MAFFITT) 14.

• **Blasting cartridge for use with liquid air.** SPRENGLUFT GES. AND L. LJSSE. Brit. 232,885, Feb. 19, 1925. A blasting cartridge adapted to be impregnated with liquid air is charged with a compn. contg. cork or wood 25% admixed with NaCl, sugar, soda, borax, alum, chalk, $(\text{NH}_4)_2\text{SO}_4$ or NH_4Cl .

Dropping and exploding blasting charges in hardpan or other refractory formations to be excavated. F. W. CAMP. U. S. 1,560,038, Nov. 3. Mech. features.

25— DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

• **Aniline black.** BONUS. *Farbe und Lack* No. 44, 517-8(1925).—Review.

Printing of aniline black. W. R. MCKENNON. *Textile Colorist* 47, 578(1925).
F. A. WERTZ
CHAS. E. MULLIN

Casein dye compounds. H. O. RASSER. *Kunststoffe* 15, 91-2(1925).—Formulas are given for various compositions contg. casein. C. J. WEST

Chrome colors on wool. L. J. MATOS. *Dyestuffs* 26, 133-4(1925). C. E. M.

Bleaching and dyeing of towelings. ISMAR GINSBERG. *Textile Colorist* 47, 701 2(1925) — Fast color towelings should be dyed only with vat dyes, about 33% excess of hyposulfite being used. Naphthol AS may be used for red. It is claimed that a previous treatment of the fabric with a 2 or 3% soln. of AcOH prevents the usual bleeding of reds on bleaching. S blacks are also used. Indanthrene blue and alizarin cyanol E or B are recommended for *bluing*. CHAS. E. MULLIN

Mordant reds for silk. H. W. WILSON. *Textile Colorist* 47, 734(1925).—The color obtained from alizarin red and alizarin bordeaux on silk mordanted with Al or Cr are considered as regards fastness. CHAS. E. MULLIN

The composition of some products used for the production of insoluble azo colors. F. M. ROWE AND ESTHER LEVIN. *J. Soc. Dyers Colorists* 41, 354-6(1925).—Naphthol AS-BR (GrE) is probably the dianisidide of β -hydroxynaphthoic acid. Naphtholate AS (GrE) is the Na salt of Naphthol AS to which sol. oil has been added to render the former more sol. Brenthol H Soluble 50% Paste (British Synthetics Ltd.) (S) is an aq paste of a readily sol. combination of Naphthol AS and pyridine. Baths prepd. with this paste may be kept almost indefinitely without oxidation or polymerization. The various bases in the following list were identified by diazotizing and coupling with β -naphthol and Naphthol AS, resp., followed by crystn. and detn. of m. p.: Fast Garnet base CL (JWL), Fast Garnet base L (JWL), Fast Garnet GB base (GrE), and Fast Garnet GC base (GrE) are *o*-aminoazotoluene. Fast Red base GL (JWL) and Fast Red GI base (GrE) are 5-nitro-2-aminotoluene. Fast Scarlet GL base special (JWL) and Fast Scarlet G base (GrE) are 4-nitro-2-aminotoluene. Fast Scarlet base GCL (JWL) and Fast Scarlet GG base (GrE) are the hydrochlorides of 4-nitro-2-aminotoluene. Fast Scarlet base 2GL (JWL) and Fast Scarlet GG base (GrE) are 2,5-dichloroaniline. Fast Yellow base GL (JWL) and Fast Yellow G base (GrE) are *o*-chloroaniline. Fast Yellow base GCL (JWL) and Fast Yellow GC base (GrE) are the hydrochlorides of *o*-chloroaniline. By other methods it was detd. that Fast Orange base (GrE) is *m*-chloroaniline. Fast Red KB base (GrE) is the hydrochloride of 4-chloro-2-aminotoluene. Fast Red Salt B (GrE) is stabilized diazotized 5-nitro-2-aminoanisole. Fast Red Salt GG (GrE) is stabilized diazotized 2,5-dichloroaniline. Fast Red Salt GI (GrE) is stabilized diazotized 3-nitro-4-aminotoluene. Fast Scarlet Salt R (GrE) is stabilized diazotized 4-nitro-2-aminoanisole. Permanent Red 2G (AGFA) and Monolite Red 2G (BCD) are identical and when crystd. from glacial AcOH m. 302°. This m. p. was not depressed by admixture with the azo compd. formed by coupling diazotized *m*-dinitroaniline with β -naphthol. L. W. RIGGS

Red and green shades of indanthrene blue RS and GCD. ADOLPH ZIMMERFELD. *Chemicals* 24, No. 15, 19-20(1925).—Z. gives expts. which support his theory that the redder shade of indanthrene RS and GCD is caused by the oxidation of the oxalic (carboxylic) H, while the greener shade is due to the oxidation of the imino H of the hydrazine group.

CHAS. E. MULLIN

Dyeing with Indanthrene Blue GCD. GUSTAV DURST AND HANS ROTH. *Textilber.* 6, 837-9(1925).—By analyzing some lab. and practical scale vats at intervals, it was found that reducing power of the liquor falls off rapidly during the first 30 min. working, but then reaches a min. The NaOH content falls off rapidly following introduction of the yarn, but very soon reaches a min.

E. R. CLARK

A study of certain derivatives of *p*-cymene, with special reference to possibilities of utilization (in dyestuffs). R. E. SARGENT AND F. W. HIBBARD. *Textile Colorist* 47, 561-5(1925).—The literature upon the chlorination, nitration and sulfonation of *p*-cymene is discussed. S. and H. were not successful in brominating it. They prepd. the benzidine homolog, dimethyldiisopropylbenzidine (I), which closely resembles benzidine, by suspending 1 vol. of nitrocymene in 4 vols of 25% alc., adding 2 vols. of alc. KOH while boiling and then Zn dust. The isomer, dimethyldiisopropylidiphenylene (II), which is very unstable, was formed simultaneously. Cymene was nitrated according to Wheeler and Smithy, reduced with Fe and HCl, diazotized and coupled with various (21) components to form monoazo dyes. I was tetrazotized and coupled as the first component of 11 combinations for direct dyes, while II was treated in the same manner with 6 combinations. Acid dyes also were prepd. In nearly every case the color tones of the dycings were darker than the corresponding dyes from benzidine or *o*-toluidine.

CHAS. E. MULLIN

Restraining dyes in dyeing. C. F. GREEN. *Textile Colorist* 47, 577(1925).—In order to obtain more even dyeings, it is suggested to work cotton yarn in a Na_2CO_3 soln before adding the direct dye or salt. Before dyeing tannin mordanted, or topping direct or S dyes cotton with basic dyes, the goods may be worked in an AcOH bath.

CHAS. E. MULLIN

Roughness of dyed silk hosiery. C. E. BICK. *Am. Dyestuff Rept.* 14, 717(1925).—Roughness in real silk is caused by excessive mech. action. Machines that will dye successfully with the least amt. of friction on the goods should be selected.

L. W. R.

Chats with the textile chemist. J. MERRITT MATTHEWS. *Textile World* 68, 2633-4, 2697(1925).—A discussion of the present status of the *adsorption theory of dyeing*, and *moisture in cotton*.

CHAS. E. MULLIN

Cleaning solution for the dye laboratory. C. F. GREEN. *Textile Colorist* 47, 614(1925).—A hot mixt of H_2SO_4 and HNO_3 is recommended as better than dichromate and H_2SO_4 . Sufficient HNO_3 should be used to keep the soln. nearly colorless.

CHAS. E. MULLIN

Proposed system of tests for the fastness of dyestuffs on wool. H. R. HIRST. *J. Soc. Dyers Colorists* 41, 347-54(1925).—The fastness requirements of the manufacturer and of the wearer are described, also the details of making the tests.

L. W. R.

Detection of oxycellulose in dyed cotton. E. RISTENPART. *Textilber.* 6, 830(1925).—The detn. of Cu numbers of dyed cotton is complicated by the fact that most dyestuff fix a certain amt. of Cu. Therefore a blank test on dyed material free from oxycellulose must be made, the test dyeing being dyed to match. The HNO_3 ext. may be evapd. to dryness, ignited and fused with KHSO_4 prior to detg. Cu colorimetrically or otherwise, to remove org. matter.

JAMES CHITTICK. *Ibid* 1776-8. **Dyeing of rayon hosiery.** H. C. ROBERTS. *Ibid* 1785-6. **Dyeing rayon in the skein.** E. F. JAMES. *Ibid* 1788-90. **Scouring and bleaching rayon.** ANON. *Ibid* 1790-1. **Standardized practical tests for rayon.** W. F. EDWARDS. *Ibid* 1791-4. CHAS. E. MULLIN

The fine structure of viscose rayon. H. C. DAHLENVORD. *Textilber.* 6, 739-42, 823-4(1925).—The velocity of coagulation, which is a function of ripeness, affects the crystal structure of rayon, and in turn the character of the dyeings. The more the viscose is ripened before spinning, the less is the extensibility of the threads. Hence it seemed that the more easily stretched types of viscose rayon should dye differently from those showing little stretch. Dyeing tests made parallel to stretch and strength tests, on a variety of com. viscose rayon products, seemed to confirm the conclusion.

E. R. CLARK

Bleaching rayon waste. WALTER KOSCHE. *Textilber.* 6, 827-8(1925).—Spinning wastes may be treated in a circulating kier with 1.5% perborate and 1.0% NaOH or 1½% water glass for 1.5 hrs. at 60° and 0.5 hrs. at 70°, then rinsed well, chemicked with NaOCl soln. contg. 2 to 6 g. active Cl per l., let stand 6 hrs., washed, soured with 4% HCl and rinsed out of monopol soap soln. If the waste contains S compds. a preliminary treatment with H₂SO₄ should be employed. A final treatment with olive oil, gelatin and HOAc adds luster and improves the feel. Textile-mill waste may be handled similarly if not dyed. Little can be done with dyed mill waste. Very dirty material of this type requires soap or tetrapol in the kier.

E. R. CLARK

Changes in the length of rayon and silk threads with variations in atmospheric humidity. ALFRED OPPÉ AND KURT GOTZE. *Textilber.* 6, 850-4(1925).—Single strands of the material being examd. were suspended with a fixed wt. attached in a glass tube provided with a means for circulating air of various degrees of humidity about them, and the amt. of extension was measured. Acetate rayon, contrary to what might be expected, stretched very similarly to viscose rayon at 83% relative humidity, and in fact there was in general a greater variation between the products of different makers, than between those of different chem. manufacturers. Degummed silk stretched less than raw silk.

E. R. CLARK

German patents (relating to rayons) made available. ANON. *Textile World* 68, 2313(1925).—A list of 73 U. S. patents in the hands of the Chemical Foundation, covering the production and use of rayons, cellulose products and esters, and wool substitutes.

CHAS. E. MULLIN

Preparation of water-impenetrable fabrics. SCHWARZ. *Kunststoffe* 15, 49-53, 74-7, 137-41(1925).—Patent review.

C. J. WEST

The fastness of dyed and printed cottons to washing agents. JAS. FERGUSON. *Textile Recorder* 43, No. 510, 61-3(1925).—Washing expts. were made to det. the fastness of 46 colors to soap, Na₂O₂, NaBO₃, Persil, Ca(OCl)₂ and NaOCl. Basic dyes are not as fast to hypochlorites as to the per-salts but their poor fastness is due to their alkali sensitiveness. The direct cotton colors are no more fugitive to Persil than to soap washing, but they are more fugitive to hypochlorites. Direct colors which have been after-treated with metallic salts are fugitive to Persil, possibly as a result of catalytic action, and in this case hypochlorites cause injury to the fiber. S colors are attacked by both peroxides and Persil, and more so by hypochlorites. Most other colors are as fast to Persil as to soap. The action of hypochlorite upon the various dyes, particularly vats, varies considerably. Turkey red, aniline black, naphthol red AS, and colors developed with hypochlorite are very fast to per-salts and Persil washing. Coupled and developed colors in general have a higher fastness to Persil than towards hypochlorite or soap. A fastness table is given.

CHAS. E. MULLIN

Faults in textiles and their causes. JOVANOVIĆ. *Textilber.* 6, 831-7(1925).—Faults in cotton and wool textiles and tests for detg. their nature and causes are presented in a compact tabular form, together with a considerable bibliography.

E. R. CLARK

Printing metallic powder (on fabrics). ALBERT SCHEURER. *Bull. soc. ind. Mulhouse* 91, 469-70(1925).—Scaled Notes 1788 of Nov. 26, 1907; 2127 of Nov. 22, 1911. 2134 and 2135 of Dec. 19, 1911. No. 1788: Cooking 20 kg. of a good grade of white glue with 80 l. of water for 1 hr. at 0.5 kg. pressure gives a gelatinous mass on cooling, which has a definite liquefying point lying between 27° and 35°. The paste-metal powder mixt. must be applied to the fabric at the critical temp. Waterproofness is obtained by the action of CH₃O vapors. No. 2135: As the metal powder has a tendency to settle out when mixed with the paste, this is overcome by cooking 600 kg. of gelatin with 400 l. of H₂O for 8 hrs. at a pressure of 2 kg. Nos. 2127 and 2134: The mixt. can be printed together with algal, helindone and indanthrene dyes on a bottom which can

be removed with hyposulfite. **Report.** PHILIPPE BRANDT. *Ibid* 471-2.—The process is cheap and gives good results. Care must be taken when the printed fabric must be subsequently washed, as the paste is not very resistant to rubbing when the fabric is wet. No anteriority was found. A. PAPINEAU-COUTURE

(Printing) alizarin rose and red (on fabrics). Method of eliminating iron. ALBERT SCHEURER. *Bull. soc. ind. Mulhouse* 91, 473(1925).—Scaled Note 1839 of May 20, 1906. Presence of basic Al chloride prevents alizarin rose and red from turning to violet on steaming, even in the presence of Fe; e. g., $Al_2Cl_3(OH)_4$ dissolved in AcOH, can be added to the mordanting soln. **Report.** PIERRE BINDER. *Ibid* 474.—S's claim was easily verified. No anteriority was found. A. PAPINEAU-COUTURE

Modern equipment (in the textile industry). ANON. *Textile Colorist* 47, 103-6, 171-4, 239-42, 307-10, 375-8, 443-6, 511-4, 579 82, 656 9(1925).—A description of various types of app., its uses and advantages. CHAS. E. MULLIN

Why new fabrics and fibers. H. G. BEEDE. *Textile World* 68, 2479, 2493-7, 2509(1925).—An address in which the prepn., uses and properties of *rhea* are described. CHAS. E. MULLIN

Transient decrease in the strength of cotton fabrics by dehydration at high temperatures. FÉLIX DRIESSEN. *Bull. soc. ind. Mulhouse* 91, 475-8(1925).—The strength of cotton fabrics is shown to be considerably reduced when they are very dry, but is restored when they reabsorb moisture. A. PAPINEAU-COUTURE

Purification of cotton linters. W. W. CHASE. *Textile World* 68, 1479-81(1925).—A discussion of the app., methods, materials, labor, records and costs of scouring linters. CHAS. E. MULLIN

Methods of drying wool. BROMPTON. *Textile World* 68, 2175, 2181(1925).—General. CHAS. E. MULLIN

The bleaching, dyeing and finishing of cotton fabrics containing rayon. R. W. ARRINGTON. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 192-4; *Am. Dyestuff Rept.* 14, 726-8. —Cotton threads will stretch and recover. Rayon threads have practically no resiliency. These facts govern the methods of handling fabrics contg. both cotton and rayon. L. W. RIGGS

Artificial silk industry. ANON. *Papir-Journalen* 13, 159-62(1925).—Various mfg. methods for artificial silk are compared. Tonnage and percentage produced in different countries are given. W. SEGERBLUM

The artificial silk industry. EUGENE GRANDMOUGIN. *Génie civil* 84, 33-6, 57-61(1925). JACK J. HINMAN, JR.

Artificial silk and the textile industry. G. J. ESSELEN. *Am. Dyestuff Rept.* 14, 713-7(1925).—The methods of manuf. and the properties of the 4 leading kinds of artificial silk are described. L. W. RIGGS

Silk and its testing. J. O. THOMPSON. *Textile Colorist* 47, 221-3, 293-5, 370-1, 374, 431-3(1925).—A discussion of the various tests and their applications. C. E. M.

Caustic soda discharges which do not affect printing rolls. WILHELM SIEBER. *Textilber.* 6, 829-30(1925).—Gum arabic or senegal soln. may be treated with successive small portions of the necessary amt. of NaOH in 36-40° BÉ. soln., along with const. stirring and removal of heat. E. R. CLARK

Caustic soda as a mercerizing agent for linen. ISMAR GINSBERG. *Textile Colorist* 47, 629-32(1925).—Mercerizing linen fabric, with or without tension, increases the luster and dyestuff affinity. The strength is decreased about 10% but the elasticity is increased. CHAS. E. MULLIN

Starch. JOSEPH WOODMAN. *Textile Colorist* 46, 717-9, 783-6(1924); 47, 232-4, 640-1(1925).—Starch is considered from the standpoint of its textile uses. C. E. M.

Jute fiber and its applications. W. VAUBEL. *Textilber.* 6, 805-6(1925).—Prior to the war the German jute industry had been increasing along with a decline in the flax and hemp industry. The war revived the latter and they are again growing, but the jute industry is also expanding rapidly. Efforts are being made to produce jute products of higher quality. Abstracts of patents, etc., are cited as suggestions for bleaching, improving fine spinning characteristics, cottonizing, dyeing and pulping wastes. E. R. CLARK

Sodium fluoride in cold-sizing materials. E. O. RASSER. *Kunststoffe* 15, 151-3(1925).—NaF in cold-sizing materials serves 2 purposes: as a preserving agent and as an adhesive. Various formulas are given for starch, dextrin or casein products contg. NaF. C. J. WEST

"Cold size." ANON. *Kunststoffe* 14, 54-6, 118-20(1924).—The name "cold size" is applied to products that are used at room temp. The dry cold sizes consist

of products from starch, dextrin or casein; these same products and waste sulfite liquor are also used in the liquid form. Various formulas and uses are given. C. J. WEST

Textile mill soaps (HAYES) 27. Dyes derived from oxalyldibenzyl ketone (CHAKRAVARTI) 10. The reducing power of waste sulfite liquor and its use in dyeing and bleaching (KOTIBHASHIKER) 23. Standardization of the analysis of sulforcinates (GALTIHERN, SUNDER) 27. Modified casein [for sizing cloth] (U. S. pat. 1,551,471) 18.

Dyes. BADISCHE ANILIN & SODA FABRIK. Brit. 232,799, May 24, 1924. Dyes producing gray to black shades on cotton from the vat are produced by treating nitrated dibenzanthrone with S or a S-yielding material, with or without a "transporter" such as Cu oxide or Sb₂S₃. A temp. of 240–250° may be used in forming the dyes.

Dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 232,620, April 20, 1924. The process of Brit. 207,162 (C. A. 18, 1206), according to which azo dyes are obtained by coupling an *o*-diazonaphthol with 1-hydroxynaphthalene-8-sulfonamide, is extended to the coupling of any *o*-hydroxydiazo compd. with any hydroxynaphthalenemono (or poly-) sulfonamide. The products dye wool various shades which may be after-chromed or after-coppered. Numerous examples are given. Hydroxynaphthalene-sulfonamides are obtained from the corresponding naphtholsulfonic acids by acylating the -OH group, converting the sulfo group into the sulfochloride and then into the sulfonamide group, and finally eliminating the acylidyl group.

Dyes. FARBENFABRIKEN VORM. F. BAYER & Co. Brit. 232,740, March 11, 1924. An orthoformic ester or a salt of formic acid or β -alkyloxy-acroleinacetal is condensed with a cyclammonium salt contg. a reactive Me group in the α -position to the N. α -Methylindolenium salts, the μ -methylbenzoxazolium salts and the μ -methylbenzthiazolium salts may be used. Red, blue and violet dyes are produced with various starting materials. α , β , β -Trimethylindolenium compds. of the naphthalene series (which may be used to form blue dyes) are prepd. by condensing 1- or 2-naphthylhydrazine with acetone or other ketone, melting with ZnCl₂ and alkylating the indole obtained to introduce 3 alkyl groups.

***o*-Hydroxyazo dyes.** O. KALTWASSER, H. KIRCHHOFF and H. OEHRN. U. S. 1,556,329, Oct. 6. The diazo compd. of 2-amino-4-nitro-1-hydroxybenzene-6-sulfonic acid or other sulfonated *o*-hydroxydiazo compd. is combined with an unsulfonated 1-naphthyl-3-methyl-5-pyrazolone. The after-chromed tints and tints produced by dyeing with chrome mordants by the resulting dyes are orange to bluish red of good fastness to light and staining.

Monoazo dyes. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 232,629, April 19, 1924. Sulfonated *o*-hydroxydiazo compds. are coupled with unsulfonated 1-naphthyl-3-methyl-5-pyrazolones. The products yield fast orange, bluish red, etc., shades when dyed on wool with a chrome mordant or when after-chromed. Several examples are given.

Dyeing "acetyl silk," etc. FARBWERKE VORM. MEISTER, LUCIUS and BRÜNING. Brit. 232,599, April 15, 1924. A violet-black is obtained by treating "acetyl silk" with the glycine of α -naphthylamine, diazotizing, and developing with β -hydroxynaphthoic acid. A yellow color is produced by the glycine of aminoazobenzene, violet with the glycine of 1,4-diaminoanthraquinone, and blue and reddish violet, resp. by the glycines of 1,4,5,8-tetraaminoanthraquinone and of 1-amino-4-hydroxyanthraquinone. Acids, salts or protective colloids may be added to the dye bath.

Benzene derivatives for dyestuffs. H. G. STONE and B. H. JACOBSON. Can. 254,834, Oct. 20, 1925. A mixt. of phthalic anhydride and anhyd. AlCl₃ is ground, benzene is introduced during the grinding which is continued for several hrs., the excess benzene is evapd. and the resulting AlCl₃ compd. of *o*-benzoyl-benzoic acid is obtained in dry finely divided form.

Phenol-sulfur compounds for use as mordants. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 232,958, April 24, 1924. Colorless S-contg. compds. suitable for use as mordants for basic dyes are obtained by heating (suitably at about 170°) with a phenol-sulfonic acid the resinous substances produced by treatment of phenols with S chloride.

Artificial silk from nitrocellulose. E. BINDSCHEDLER. U. S. 1,562,076, Nov. 17. Nitrocellulose hydrate dissolved in a mixt. of alc. and ether is exuded through orifices and the formed product drawn away and coagulated in a bath contg. EtOH or other similar alc. and glycerol. The drawing is effected at a speed greater than that of exudation.

Artificial silk from viscose solutions. W. P. DREAPER. Can. 255,256, Nov. 10,

1925. The viscose soln. is extruded from the spinning jet into an acid salt pptg. bath contg. not less than 4 or more than 10% of a Zn salt and about 20% of Na_2SO_4 .

Fibers from flax and hemp. C. DUBOIS. Brit. 232,935, April 26, 1924. Flax or hemp, freed from shives by retting or scutching, are treated with hot alk. solus. or other solvents to remove gummy and resinous substances, washed and passed through opening and carding machines. The silky fibers thus obtained are treated with oil or varnish, pressed and smoothed.

Apparatus for treating cotton or other fibers with oil, etc. C. C. SELDEN and R. D. PEARSON. Brit. 232,947, April 28, 1924.

Mothproof felt, etc. B. A. STAGNER. U. S. 1,558,122, Oct. 20. A soln. contg. an arsenical compd. such as Na arsenite, soap, and glue or other adhesive is used for coating the fibers of a hair fabric.

Bacillus felsineus cultures. D. CARBONE. U. S. 1,556,489, Oct. 6. *Bacillus felsineus* cultures are prepd. by using recipients contg. hemp cut into pieces, placed in H_2O and sterilized and bringing these into contact with *Saccharomyces ellipsoidus*, cultivated separately, *e. g.*, in a malt decoction. Cultures thus prepd. are adapted for macerating hemp.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Painting technic and colloid chemistry. HUGO KÜHL. *Farben-Ztg.* 31, 154-5 (1925).—Some of the directions of the early artists, especially in fresco and tempera colors, for the prepn. of the surface and the application of the paints, were founded on principles which are now recognized as colloidal phenomena.

F. A. WERTZ

Tar as a paint. F. O. RASSER. *Kunststoffe* 15, 131-4 (1925).—Tar is of general use where resistance to weathering is important and the esthetic side is unimportant.

C. J. WEST

Lead salts and their use in color manufacture. ANON. *Farben-Ztg.* 31, 26-8 (1925).—Review.

F. A. WERTZ

Rust-proof paints—iron lacquers—asphalt lacquers. F. O. RASSER. *Asph. u. Teer Ind. Zeit.* 25, 506-7 (1925).—A review of the requirements of a rust-proof paint with a brief discussion of those in use.

M. B. HART

Determination of asbestine in lithopone paint. F. G. GERMUTH. *Ind. Eng. Chem.* 17, 1150 (1925).—The extd. paint pigment contg. only lithopone and asbestine, is treated with acid NH_4OAc . The insol. residue is fused with Na_2CO_3 and K_2CO_3 , and the resultant BaCO_3 and the unattacked asbestine are sepd. from the leached fusion. The BaCO_3 is dissolved in dil. HCl , the asbestine filtered on a Gooch crucible and weighed after drying at 105° , and the Ba detd. in the filtrate as sulfate. Accurate results are obtained.

F. A. WERTZ

Lead suboxide as a pigment. A. V. BLOM. *Farbe und Lacke* 1925, No. 43, 504-5.—Theoretically, Pb_2O can react with linseed oil in the presence of moisture and air to produce Pb soaps, metallic Pb, and eventually $\text{Pb}(\text{OH})_2$. The behavior of Pb_2O in certain reactions suggests that one of the Pb atoms is more closely attached to the O atom than the other; and the variable reactivity of Pb_2O from different sources, which cannot be explained by variations in degree of dispersion, suggests that the structure may lie between the extremes of Pb_2O as a chem. compd. and PbO plus Pb as a phys. mixt. When a Pb_2O -linseed oil mixt. is examd. in a thin layer under a polarizing microscope, anisotropic formations appear around each pigment particle after 1 day. These birefringent formations of Pb soaps grow until the inter-particle space is eventually bridged over. Similar soap formations can be observed when other basic pigments are mixed with free fatty acids. When Pb_2O in linseed fatty acids with access of air is observed in the polarizing microscope or by dark field illumination, characteristic threads of oleate surround each pigment particle in a short time; this does not occur in absence of O. With limited access of O, it is sometimes possible to observe the mass of oleate threads spangled with minute opaque spots which are perhaps highly dispersed metallic Pb. These spots disappear on further access of air through formation of oxide and subsequent soln. in the fatty acid. The same reactions that occur in the fatty acid, occur more slowly in the glyceride, and they finally produce a paint film of increased elasticity and impermeability. An indication of the existence of Pb suboxides of different structures and reactivities is afforded by expts. on 4 vulcanized rubber compds. of identical compn. except contg. different samples of Pb_2O of similar particle

size. These rubber compds. were graded according to their structure detd. by microchem reactions in the polarizing microscope, and the grading arrived at was the same as that shown by tensile-strength measurements. The best pigment structure gave nearly twice the tensile strength of the poorest. The polarizing microscope can be used advantageously for studying rubber structure, and shows analogies between the dispersoid-chem. structures of rubber compds. and paint films. Illus. F. A. W.

New rust-preventive paint. HANS REBS. *Farbe und Lacke* 1925, No. 11, 124.—R. disputes that Pb_2O used as a pigment with linseed oil, gives up its O to the oil and deposits a film of metallic Pb; and other claims made for this pigment. A reply (W. PFLUGER, *Ibid*) is appended. F. A. WERTZ

Grape-seed oil as a paint oil. ANON. *Farbe und Lacke* 1925, No. 11, 125.—A review of phys. consts. drying characteristics, compn., etc. F. A. WERTZ

Poisonous paints. ANON. *Farbe und Lacke* 1925, No. 11, 129-30.—A review of the German laws governing the use and manuf. of pigments injurious to the health. Observations suggest that the danger from the handling and use of white lead, and other poisonous pigments is not as great as is often assumed. F. A. WERTZ

Luminous pigments. ANON. *Farben-Ztg.* 31, 401-3(1925).—A review of the discovery of phosphorescent mineral substances, of the requirements and causes for their phosphorescence, and of the uses and properties of pigments made with them and with radioactive constituents. F. A. WERTZ

Titanium white. SCHEIBER. *Farbe und Lacke* 1925, No. 44, 515-6, 527.—A review of methods of manuf. and properties. F. A. WERTZ

The use of Prussian blue in painting. ANON. *Farben-Ztg.* 31, 218-20, 276-9 (1925).—A review of the manuf., properties and uses of Prussian blue. F. A. W.

The genesis of the earth color mill. P. W. RICHTER. *Farben-Ztg.* 31, 223(1925).—A brief historical review of grinding operations from primitive times. F. A. W.

Heavy spar. ERICH STOCK. *Farben-Ztg.* 31, 341-2(1925).—A review emphasizing the legitimate uses of barytes as an extending pigment in paints. F. A. WERTZ

The German lead pigment industry from the standpoint of hygiene. ANON. *Farben-Ztg.* 31, 346(1925).—A review of the brochure by K. B. Lehmann, 95 pp. (Julius Springer, Berlin). F. A. WERTZ

Black drawing ink. ANON. *Farben-Ztg.* 31, 37-8(1925).—A review of the manuf. of drawing and India ink in liquid and tablet form. F. A. WERTZ

Manufacture of linoleum. J. A. PALMER. *Kunststoffe* 14, 148-9(1924).—General review. C. J. WEST

Manufacture of linoleum, artificial leather, etc. SCHWARZ. *Kunststoffe* 14, 161-4, 177-81(1924), 15, 34-8(1925).—Patent review. C. J. WEST

The running of varnishes. A. FREY. *Farbe und Lacke* 1925, No. 44, 518.—The "running" of varnishes after application may be due to "slack melting" of the gum, too low an oil content with certain types of gum, an excess of Pb driers, unfavorable humidity conditions, the presence of combustion products in the air, etc. F. A. W.

Linseed-oil varnishes—wood-oil varnishes—cellulose lacquers—a cross section. H. RASQUIN. *Farben-Ztg.* 31, 91-2(1925).—A comparative review of the properties and uses of these different types of varnish coatings. F. A. WERTZ

Fire-protecting varnishes. E. O. RASSER. *Kunststoffe* 15, 171-3, 199-200 (1925).—Various preps. are discussed, with special reference to the use of water glass. C. J. WEST

Sediments in varnishes and lacquers. HANS WOLFF. *Farben-Ztg.* 31, 29-32 (1925).—Investigation of a wood oil-linseed oil-hardened rosin varnish that had become mushy after 6 mo. storage, showed that the sepg. material was a double Pb salt of abietic and stearic acids. The sediment in another dark-colored varnish was found to be a mixt. of Pb acid resinate and Pb stearate with small quantities of other fatty and hydroxy acid salts. A third sediment contained Pb, glycerol and abietic acid in proportion to suggest a Pb monoglyceryl abietate with another mol. of abietic acid as a loosely held addition product. Details of the identification tests and analyses are given (cf. C. A. 19, 3603). F. A. WERTZ

The color determination of varnishes, oils, etc. HANS WOLFF. *Farben-Ztg.* 31, 34(1925).—I solns. as recommended by Fonrobert (C. A. 20, 117) are preferred as color standards, but the designation is more conveniently expressed by the *N* factors of the I solns. than in mg. of I per 100 cc. F. A. WERTZ

The determination of color of varnishes, oils, etc. HERMANN VOLLMANN. *Farben-Ztg.* 31, 338(1925).—I solns. as color standards (cf. preceding abstract) are not absolutely permanent. For this reason they were displaced as color standards in the brewing industry by mixed solns. of $K_2Cr_2O_7$ and $CoSO_4$, which are much more permanent and

whose color is designated as the amt. of 0.1N I soln. which must be added to 100 cc. H₂O to obtain the same color. Such solns. do not undergo color changes in several years and are therefore better working standards, even though I solns. may serve for lab. use where the I may be readily titrated at the time color comparisons are made.

F. A. WERTZ

The standardization of driers. P. MÜLLER. *Farben-Ztg.* 31, 339-41(1925).—A plea for the standardization of com. prepd. driers as supplied to varnish manufs. They should consist of pptd. or fused linoleates and resinsates of Pb, Mn and Co with a defined content of the available metal. Suspended metallic oxides often present in fused resinsates are not in available form to be taken up at the low temp. at which driers are often incorporated into the varnish bases.

F. A. WERTZ

Decalin and hydroterpinol varnishes. E. O. RASSER. *Kunststoffe* 15, 53-4, 77-9 (1925).—The possible substitution of decalin for turpentine is discussed; its use and that of hydroterpinol in varnishes is indicated, formulas being given and the properties of such products reported.

C. J. WEST

The production of kauri copal. FELIX FRITZ. *Farben-Ztg.* 31, 156-8, 220-2 (1925).—Illus.

F. A. WERTZ

Melting copals with exclusion of air with carbon dioxide. E. GASKA. *Farben-Ztg.* 31, 158-9(1925).—A gum-melting kettle provided with CO₂ inlets at the top and at the bottom below the surface of the gum, and the method of operation are described. Better gum melts, lighter-colored varnishes, and more easily cleaned kettles result by the method than if conducted in the usual way with access of air.

F. A. WERTZ

Linseed oil diluent or substitute. E. O. RASSER. *Kunststoffe* 14, 146-8(1924).—Discussion of the product "Linil," which, mixed with linseed oil, permits it to be diluted with H₂O. The use of perilla oil is also discussed.

C. J. WEST

Wood oil (tung oil, Chinese wood oil, etc.). E. O. RASSER. *Kunststoffe* 15, 111-2(1925).—Brief discussion of wood oil and its substitutes

C. J. WEST

Oxidation of Chinese wood oil. F. H. RHODES AND T. T. LING. *Kunststoffe* 15, 157-8(1925); cf. *C. A.* 19, 1783

C. J. WEST

The unsaponifiable constituents of commercial rosins, with notes on rosin oil and on the polymerization of turpentine. EDMUND KNECHT AND N. B. MAURICE. *J. Soc. Dyers Colourists* 41, 356-61(1925).—From the unsaponifiable constituents of the com. rosins examd. were isolated pinene, 3 hydrocarbons of the compn. C₂₂H₃₂ and b 270-278°, 315-320° and 360-370°, resp., and a hydrocarbon C₁₉H₃₀, b. 335-340°, this being identical with colophene. No compds. contg. O were found. Resin as it comes from the tree contains a much larger proportion of turpentine than does com. rosin, and there is no colophene present. Only Varyan rosin contained C₂₀H₃₂, m. 360-370°. The 3 hydrocarbons of the compn. C₂₂H₃₂ were proved to be identical with diterpenes of the same b. p., formed by polymerization of turpentine by heat, or, in the first 2 cases, by treating turpentine with 85% H₂SO₄ at 0°. No colophene was found in gum thus, and the presence of this hydrocarbon in com. rosin suggests that it is formed during the distn. process by the decompn. of the rosin acid. The 3 diterpenes mentioned are unaffected by alk. permanganate but are oxidized completely by acid permanganate. They are not dehydrogenated by the usual methods and they form substitution products with Br. They do not form nitrosochlorides or nitrosites and do not combine with HCl gas.

L. W. RIGGS

Report on naval stores. (Determination of the softening and melting points of rosin.) F. P. VEITCH. *J. Assoc. Official Agr. Chem.* 8, 710-3(1925).—A "capillary-tube method" for softening and m. points and a "drip method" for m. p. of rosin are described in detail. Results of collaborative tests by the capillary tube method for softening point and by the drip method for m. p. were very satisfactory. The max. and min. figures for m. p. by the capillary-tube method were decidedly wide (possibly because of lack of familiarity of the operators with the method). The drip method gives results about 10° higher than the capillary-tube method for m. p., and is more a yielding- or softening-point method than a m.-p. method.

A. PAPINEAU-COUTURE

Two-type lacquer solvents. D. B. KEVES. *Ind. Eng. Chem.* 17, 1120-2(1925).—Mixts. of ethers and alcs., esters and alcs., etc., are better solvents for nitrocellulose than either solvent alone. A single compd. having the properties of both an alc. and an ether or an ester, such as the monoethyl ether of glycol, or Et lactate represents a two-type solvent which in general is a powerful solvent for nitrocellulose and for resins. A list of the simpler compds. that fall within the two-type group is given, with graphic formulas, b. ps., an indication of how they can be made, and any reference to their use in lacquers.

F. A. WERTZ

Evolution of hydrogen peroxide by oils on exposure to light. G. F. A. STUTZ,

H. A. NELSON AND F. C. SCHMUTZ. *Ind. Eng. Chem.* **17**, 1138-41 (1925).—The comparative quantities of H_2O_2 evolved by drying and semi-drying oils and by dry oil films, especially after exposure to light, were detd. by the relative opacity of the images they produce on a photographic plate. On varying the time of exposure to light, the drying oils reach a max. evolution of H_2O_2 in 2 hrs. exposure; the non-drying oils show a steadier increase with no max. The addn. of free fatty acids to linseed oil did not increase the evolution; this is not in accord with previous reports (C. A. **19**, 2172). The effects of humidity, addn. of pigments, metallic soaps, etc. were detd. The region of the spectrum which is most effective in causing evolution of H_2O_2 is restricted to the blue and ultra-violet with a decided max. at 4300 Å. U. to 3000 Å. U. Sensitivity curves, tabulations, spectrograms, etc. are given. F. A. WERTZ

The emulsions of coumarone resin. ANON. *Farbe und Lacke* **1925**, No. 13, 505. A very brief review of the mfg. processes, properties and uses of coumarone resins. Electrostatic or centrifugal forces, addn. of certain colloids, etc., avoid troublesome emulsions sometimes formed in the mfg. process. F. A. WERTZ

Some plant gums of the Southwestern United States. ERNEST ANDERSON, LILA SANDS AND NELSON STURGIS. *Am. J. Pharm.* **97**, 589-92 (1925).—*Cholla gum* from the white cholla cactus, *Opuntia fulgida*, is pale yellowish white to a dark red, has a faint characteristic odor and taste, d. 1.34-1.58. In 50 times its wt. of cold water approx. 40% dissolves after 48 hrs. On the boiling water bath after 10 hrs. 50% dissolves. Slightly more of the gum will dissolve in strong NaOH soln. and in strong ammonia soln. Org. solvents dissolve only traces of the gum. When mixed with 10 times its wt. of water it swells up to a gelatinous mass. As it came from the plants the gum contained moisture 8.65, ash 5, N 0.40, ether ext. 0.15, total reducing sugar after hydrolysis with 4% H_2SO_4 , detd. by Fehling soln. and calcd. as glucose 63, pentosans 67, galactose, calcd. from the mucic acid detn., 14%. The fresh soft gum lost 45% on drying to const. wt. *in vacuo* over H_2SO_4 . The ash contained SiO_2 3.59, unburned C 3.75, CO_2 27.57, SO_4 2.97, Cl 4.67, P_2O_5 0.94, CaO 36.71, MgO 8.7, Fe_2O_3 and Al_2O_3 0.40, Mn_2O_3 0.40%. The water and ammonia solns. of the gum are faintly levorotatory. The aq. soln. is faintly acid to litmus and to methyl red. The gum is partially pptd. from soln. by 95% alc. and by solid $(NH_4)_2SO_4$, but not by $FeCl_3$ or $Pb(OAc)_2$. A few starch grains were detected. In 4% H_2SO_4 on the boiling water bath approx. 11% remains insol.; this insol. material is chiefly cellulose. *l*-Arabinose is one of the products of hydrolysis. Solns. of the gum in water, ammonia or NaOH soln. do not reduce Fehling soln. *Mesquite gum* is found on the mesquite tree, *Prosopis juliflora*, and other species of mesquite. The gum varies from light amber through a pale yellow to a dark brown, d. approx. 1.5. It is completely sol. in cold water. When the clear soln. is heated in the boiling water bath it becomes cloudy. The pH of the aq. soln. is approx. 5. The gum is practically insol. in the ordinary org. solvents. Gum that had been collected and kept in the lab. for many months contained moisture 11, ash 2.13, N 0.70, pentosans 60, galactose 11%. The ash contained unburned C 6.23, SiO_2 4.52, CO_2 29, SO_4 1.42, P_2O_5 0.35, Cl 4.51, CaO 40.88, MgO 6.71, Fe_2O_3 and Al_2O_3 0.93%. A 6.38% aq. soln. of the gum had $[\alpha]_D^{20}$ 59. The aq. soln. of the gum is much less viscous than that of gum arabic. A 10.16% aq. soln. is 3.923 times as viscous as water at 29°. *Mesquite gum* in 10% water soln. gives a faint brownish red coloration with ferric chloride soln. but no ppt. with either ferric chloride soln. or lead acetate soln. The gum is pptd. by 95% alc. *l*-Arabinose in yield of 36.5% was obtained by hydrolysis of the gum. W. G. GAESSLER

Gum-melting kettles. H. KÖLLN. *Farben-Ztg* **31**, 280 (1925). F. A. W.

Toxicity of solvents for rubber, resins and cellulose esters (KOHN-ABREST) 30. Resinates of Pb (UZAC) 10. Polishes and polishing varnishes (ZIMMER) 18. Floor covering (U. S. pats. 1,562,382-7) 20. Purifying waste waters containing H_2SO_4 (U. S. pat. 1,557,188) 18.

SPROXTON, F.: **Cellulose Ester Varnishes.** ERNEST BENN, LTD. 158 pp. \$4.50. 15 s., by post, 15 s. 6 d. Reviewed in *Munic. Eng.* **76**, 116; *J. Franklin Inst.* **200**, 828. *Engineering* **120**, 589; *Chemistry and Industry* **44**, 916 (1925).

Pigments. J. BEDFORD. Brit. 232,653, Dec. 19, 1923. A readily sol. metallic salt, e. g., Pb acetate or $ZnSO_4$, in the solid state, is added to a hot (preferably boiling) aq. soln. of Na_2CO_3 , a sol. chromate or other metallic compd. the acid radical of which

will form an insol. compd. with the metal of the added salt. Insol. pigments contg. Cu, Co, Ba and Ti and basic salts may be similarly prepd.

Pigments containing zinc compounds. P. PIPEREAUT and A. BRONNER. Brit. 232,618, April 18, 1924. Dry $ZnSO_4$ mixed with ZnS or other metal sulfide is calcined to produce a pigment which may contain ZnO alone or associated with ZnS or the oxide or sulfate of the other metal, e. g., Ti, Sb, Ba or Pb.

Water paints. R. EDSER and J. S. MARCHALL. Brit. 232,723, Feb. 8, 1924. An opaque water paint comprises cholesterol or wool fat and a hardening agent such as a mixt of casein and formaldehyde, and preferably also deflocculated kaolin or other pigment.

Calcining crude lithopone. A. S. KREBS. U. S. 1,551,197, Aug. 25. Crude lithopone is fed longitudinally through an externally treated muffle in a substantially non-oxidizing atm. and the calcined product is cooled by passing it through an externally cooled muffle extension in which a non-oxidizing atm. is also maintained.

Cyclohexanol-aldehyde resin. C. ELLIS. U. S. 1,557,521, Oct. 13. A resinous compn. adapted for forming molded articles is prepd. from cyclohexanol and formaldehyde by heating in the presence of caustic alkali.

Keto-alcohol resin. C. ELLIS. U. S. 1,557,571, Oct. 20. Ketobutyl alc is reacted on with caustic alkali at a temp. which will cause "heat-setting" to form a product which may be used for manuf. of molded articles (which may also include various fillers).

Bituminous liquid coating compositions. D. GARDNER. U. S. 1,558,082, Oct. 20. In prepg. compns. adapted for use in paints or enamels from bitumens, asphaltites, etc., a temp. of 125–140° is maintained; local overheating is avoided and the operation is carried out in a nonoxidizing atm., to avoid oxidation.

Polishing woodwork. G. RENGEL and J. PERL. U. S. 1,550,456, Aug. 18. A celluloid-resin soln. is applied to the surface of wood (considerably more rosin than celluloid is used), followed by the application of solns. contg. a larger proportion of celluloid. The finishing coat may be a pure celluloid soln.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Oxidative splitting of unsaturated acids. A. GRÜN AND F. WITTKA. *Chem. Umschau Fette Öle Wachse u. Harze* 32, 257–9(1925).—Instead of oxidizing acids of the olefin series for the purpose of identification directly by $KMnO_4$ or $K_2Cr_2O_7$, G. and W. first convert them into their corresponding acids of the acetylene series by means of Br addition and subsequent treatment with alc. KOH, then oxidize by alk. $KMnO_4$ (the last 2 reactions are quant.), or they oxidize by $K_2Cr_2O_7$. Asahina and Ishida's method in which steam is passed through the reaction mixt. With oleic acid G. and W. obtained by $KMnO_4$ oxidation pure azelaic acid, m. 106.5°, neutralization no. 596.2 (calcd. 596.7) and by $K_2Cr_2O_7$ and steam distn. they obtained almost pure pelargonic acid, neutralization no. 350.8 (calcd. 355.1). The $KMnO_4$ method is preferable, but for the purpose of prepg. pure pelargonic acid the $K_2Cr_2O_7$ method is more convenient.

P. ESCHER

A new catalyzer apparatus. ANON. *Chem. Umschau Fette Öle Wachse u. Harze* 32, 261–2(1925).—A description of a horizontal hydrogenation cylinder for 20 atm. pressure with detachable front head and fitted below with 2 gas burners for temps up to 350°; it has a substantial agitator and 2 exchangeable gas inlet tubes of asbestos-covered metal, porcelain or asbestos fabric to suit requirement, one serving as gas inlet, the other as a filter for the liquid, under treatment; a thermometer, gage, safety valve and gas exit complete the outfit.

P. ESCHER

Reaction capacity of iodine toward fats. VI. Solutions of iodine in glacial acetic acid. B. M. MARGOSCHES, L. FRIEDMANN AND E. NEUFELD. *Chem. Umschau Fette Öle Wachse u. Harze* 32, 221–4(1924); cf. C. A. 18, 2436.—Violet I solns. (in C_6H_6 , CCl_4 , $CHCl_3$, etc.) are capable only of I addition in fats, while brown I solns. (in alc., glacial AcOH, aq. KI) form III and cause addition of IOH. The reaction in alc. solns. takes place according to the equations $I_2 + HOH \rightarrow IOH + III$ and $R'CH:CHR'' + IOH \rightarrow R'CHICH(OH)R''$; solns. in glacial AcOH behave in a similar way. When HI is added to I solns. in glacial AcOH or alc. I absorption diminishes in oleic acid while addition of IOH accelerates I absorption, even to slightly beyond the normal Hübl I value. Addition of 200 cc. H_2O likewise hastens absorption in solns. of glacial AcOH, so that normal I nos. are obtained after 10 min. These latter results were obtained with linseed oil, which shows a greater soly. in glacial AcOH than other oils; but by

using abs. alc. as a fat solvent and then adding 0.2N I soln. in glacial AcOH and 200 cc. H_2O the normal Hübl value was obtained after 20 min. also for sesame oil (108.2) and a super I no. of 134.2-135.6 after 24 hrs. for sesame oil and of 214.8-216.0 for linseed oil. These super-values may be expressed by the equation $R'CHICH(OH)R' + IOH \rightarrow$ oxidation product contg. I + HI. P. ESCHER

Affinity of iodine for ethylene compounds (in different solvents. Simple and rapid method for the determination of acetyl number.) EMILE ANDRÉ. *Chimie et industrie* *Special No., 435-6(Sept., 1925); cf. *C. A.* 15, 2556, 18, 816. —A. claims priority over Margosches and Hinner (*C. A.* 18, 3731) as regards the greatly reduced reactivity of I on fats in CCl_4 or CS_2 solns., as compared with $CHCl_3$ or AcOH solns. Traces of Cu salts catalyze the absorption of I by fats: with soln. of I in AcOH contg. 0.1% CuO non-drying oils give complete absorption in 3 hrs., and non-drying and semi-drying oils give up to 80% of theoretical absorption in 2-3 days, while without catalyst it is impossible to fix more than 50% the theoretical amt. The following method is proposed for the detn. of Ac no. (defined as the no. of mg. of AcOH fixed by 1 g. of oil by esterification of the free alc. groups): in each of 2 flat-bottomed 60-cc. flasks weigh 2 g. of fat, add 25 cc. of xylene (b. 135-8°) to both, and 5 cc. of freshly distd. Ac_2O to one flask, reflux for 1 hr. in the same oil bath, distil off the C_8H_{10} at not over 175°, add 25 cc. C_8H_{10} and distil, repeat the addn. and distn. (the 3rd distillate, on shaking with H_2O should not make it acid), and finally det. the sapon. no. of the contents of both flasks. The difference between the 2 sapon. nos. multiplied by 1.071 is the Ac no. The advantages of the method are: speed and simplicity, concurrent running of blank (oil distd. in presence of C_8H_{10} shows a decrease of up to 5-6 in sapon. no.), elimination of the trouble of prep. a certain quantity of acetylated oil, which had to be washed and dried. A. PAPINEAU-COUTURE

Bromine-acetic acid reagent for determining the iodine-bromine value. L. W. WINKLER. *Pharm. Zentralhalle* 66, 581-3(1925). —A cheap and titer-stable volumetric reagent is prep. as follows: Distil about 1200 cc. of com. AcOH (rejecting the first 20 cc. and the final 100 cc.), det. the d. and adjust to a strength of 96 to 97% by addn. of H_2O . To 1000 cc. of the distd. acid add 3 cc. of Br and distil over practically the entire soln. To det. the titer, weigh into a 50-cc. Erlenmeyer flask 0.1 to 0.15 g. of castor oil, dissolve in 2 cc. CCl_4 , add 0.1 g. $HgCl_2$ and a like amt. of cryst. $AcONa$, then run in from a buret the reagent drop by drop, with const. agitation, until a permanent yellow color persists after a lapse of 2 to 3 min. On the assumption that the I-Br no. of castor oil = 84, 8.4 cc. of the reagent will be required, if exactly 0.1 N, to yield the above result. Should the no. of cc. expended be greater than 8.4, then the Br-AcOH is too weak, and may be properly adjusted by the addn. of the necessary amt. of Br. W. O. F.

The usefulness of the iodine number determined according to Margosches in the examination of oils. ERICH STOCK. *Farben-Ztg.* 31, 403-4(1925). —I nos., detd. by Margosches' method (*C. A.* 18, 2436) and by the Hübl method, on a variety of oils are tabulated; they show very good agreement. The adaptability of the much shorter and simpler Margosches method to waxes and resins is still uncertain. F. A. WERTZ

The preparation and properties of sulfonated fish oil and neats-foot oil. E. STASNY AND C. RIESS. *Collegium* 1925, 498-521. —Methods of analysis of sulfonated oils are discussed. To det. the total SO_4 heat 5 g. of oil and 100 cc. of H_2O with 10 cc. concd. HCl , either under a reflex condenser for 15 min. or on a steam bath for about 2 hrs., and det. SO_4 in the aq. portion of a H_2O - Et_2O sepn. The sulfonated portion of the oil can be sepd. in alc. by shaking the oil with equal vols. of 80% alc. and petr. ether. Fish and neats-foot oils were sulfonated under varying conditions. The fish oil could be more highly sulfonated. The amt. of organically bound SO_4 reached a max. when the amt. of H_2SO_4 used reached 30 to 40%; the I_2 no. did not fall to zero but became const. There was no relation between I_2 no. and ability to take up H_2SO_4 . The petr. ether insol. was much greater than the calcd. amt. of sulfonated product. Chrome leather took up the unsulfonated part of the oil in greater amt. and the amt. taken up decreased as sulfonating increased. Sulfonated oil was extd. by acetone but not by petr. ether. Interfacial tension between oil and H_2O was a max. at p_H 7.7. Ease of formation and stability of emulsions depended on different factors. I. D. C.

The seed oils of *Salvia sclarea* and *Cosmos bipinnatus*. S. BERLINGOZZI AND P. BADOLATO. *Boll. chim. farm.* 63, 721-3(1924). —The phys. and chem. const. are given. Owing to the high content in linolenic acid the better grades can be used as drying oils.

MARY JACOBSEN
Observations on coconut and palm-kernel oil. "Leim" fats. K. L. WEBER. *Seifensieder Ztg.* 52, 792-3, 814-5(1925). —Cold-made soaps are an unrational product.

except for use in salt-water; 6% of coconut or palm-kernel oil suffices for quick lathering ability in a soap and 10–15% is enough to produce the mottled effect in Eschweiger soaps. A high amt. of coconut oil causes absorption of considerable NaCl in settling and thereby a tendency toward "sweating" in the finished product. In shaving soaps 10–15% is permissible.

P. ESCHER

Oxygen-containing washing compounds and their keeping quality. W. SCHAEFER. *Seifensieder Ztg.* 52, 793–4(1925); cf. C. A. 19, 707.—Loss of O_2 in a washing compd. is due to the presence of H_2O in the product. When dry its keeping quality is greatest. Na silicate, when present, represents a colloidal soln and surrounds catalysts like Fe with a protective coating, preventing chem. reactions.

P. ESCHER

The chemical constitution of the compounds of sulfuric acid with the higher unsaturated aliphatic acids. H. POMERANZ. *Chem. Umschau Fette Oele Wachse u. Harze* 32, 259–61(1925).—P. discusses the various positions possible for the HSO_3 radical when H_2SO_4 acts upon unsatd. acids. He favors the grouping $-CH(OH)CH(SO_3H)-$, which assumes that the oxidation, observed in sulfonated oils after splitting off H_2SO_4 , does not occur during splitting but takes place during sulfonation by regrouping of the atoms.

P. ESCHER

Theory and practice of the manufacture of soap bases. BERGELL-LASKARAY. *Seifensieder Ztg.* 52, 822, 839(1925).—An answer to criticisms by Weber and Grosser (C. A. 19, 2753).

P. ESCHER

Standardization of the analysis of sulforcinates. HENRIETTE GALIBERN AND HENRI SUNDER. *Chimie et industrie Special No.*, 370–2(Sept., 1925).—A criticism of the methods adopted as official by the German association of Turkey red oil mfrs. G. and S. consider that results should be expressed as % by wt. of hydrated fatty acids, and suggest the following technic for its detn.: tare a wide-necked Erlenmeyer flask contg. a glass rod and a few pieces of pumice (treated with HCl and dried to const. wt.), weigh in 10 g. of sample, add hot H_2O and 20 cc. 0.1N HCl, boil till the fatty acids sep. as a clear layer, filter through double tared filters (moistened before filtering is begun), wash with hot water till the wash water is neutral, place the filter and contents in the flask, and dry carefully at not over 60° (preferably about 50°). The method is accurate to 0.25%. If insol. solids are present, they can be detd. on a sep. portion of the sample, and correction made.

A. PAPINEAU-COUTURE

Interesterification of glycerides and their technical applications. A. GRÜN. *Chem. Umschau Fette Oele Wachse u. Harze* 32, 225(1925).—Esterifying glycerides by means of alc. in inorg. acids forms ethyl esters and glycerol. Esterifying fats by means of glycerol yields mono- and diglycerides, which are used technically as such or as raw material for producing mixed glycerides contg. acids of drying oils or rosin acids. Mono-glycerides at high temps. form di- and triglycerides and glycerol. The triglyceride of 12-hydroxystearic acid, a constituent of hardened castor oil, yields glycerol and the inner esters (estolides) by direct distns. These esters are satd. glycerides with a high mol. wt. (above 3000), liquid at room temp., salve-like in the cold and viscous at elevated temp., which properties give them technical value. By heating castor oil with alc. HCl the dichlorohydrins are obtained almost quantitatively together with ethyl esters or their estolides. Interesterification of triolein, tricaprylin, tristearin, etc., occurs by heating without catalysts, and with Sn as a catalyst the mixed glycerides stearo-dicaprylin and caprylodistearin could be isolated.

P. ESCHER

The glycerides of hardened whale oil. G. GREITEMANN. *Chem. Umschau Fette Oele Wachse u. Harze* 32, 226(1925).—The original whale oil had an I no. of 145, sapon no. 192 and 0.62% free acids; it contained approx. 5% each of myristic, palmitic and stearic acids. After hardening to I no. 1, it m. 55.5° and by means of Bomer's fractional soln. and Heinz's fractional pptn. the following glycerides were isolated: (1) myristopalmitoarachin, m. 49.5° ; (2) an impure glyceride with C_{32} in its fatty acid radical, m. 53.9° ; (3) palmitostearoarachin, m. 57.3° ; (4) distearoarachin, m. 62.3° ; (5) stearoarachobehenin or palmitodibehenin, m. 65.0° ; (6) very small amts. of diarachobehenin or arachodibehenin. The acid of highest m. p. was behenic acid, 79.0° . All of the above isolated compds. had been formed by hydrogenation; the original oil had therefore contained small amts. of an unsatd. C_{14} acid, some C_{16} , C_{18} , a large amt. of C_{20} and some C_{22} acid. Apparently all were present as mixed glycerides, each contg. an unsatd. acid radical of the C_{20} or C_{22} series.

P. ESCHER

Partial saponification of mixed glycerides. K. H. BAUER. *Chem. Umschau Fette Oele Wachse u. Harze* 32, 230–1(1925).—While P. Miller has found a step-wise sapon. for the triglycerides of benzoic and myristic acid, B. and his co-workers find no step-wise decompn. when partially saponifying the following mixed glycerides: diacetyl-

benzoylglycerol, mono-*p*-nitrobenzoyldibenzoylglycerol, di-*p*-nitrobenzoylmonobenzoylelglycerol and the same glycerides of *m*-nitrobenzoic acid. P. FESCHER

Pressing or extracting. F. W. ALBRECHT. *Seifensieder Ztg* 52, 839-40(1925).—A criticism of Löffl's article (*C. A.* 19, 3606). P. FESCHER

Hardened fats and leathering ability of curd soaps. R. G. SEITENSIEDER *Ztg* 52, 851-2(1925).—Well lathering curd soaps were obtained with 50% and 60% hardened fats by keeping their NaCl content low during the final washings. P. FESCHER

A survey of equipment used in modern soap manufacture. II. C. RICHTER. *Industria saponiera* 25, 175-6(1925); cf. *C. A.* 19, 3168. —An illustrated description of agitators, frames and filter presses. III. *Ibid* 213 5.—An illustrated description of presses, cutters and driers. C. C. DAVIS

Textile mill soaps. F. A. HAYES. *Textile World* 68, 1357-61(1925).—A general discussion on the manuf., analysis and use of textile soaps. CHAS. E. MULLIN

Savonade as an emulsifier. E. O. RASSER. *Kunststoffe* 15, 71-4(1925). Savonade is a compd. of methylhexalin with an alkali soap of oleic acid, which is a viscous liquid, sol. in H₂O, and is capable of forming transparent solns. with many H₂O insol. liquid hydrocarbons. Its use in the prepn of benzene and petroleum soaps, boring oils; drawing oils, spinning oils, etc., disinfecting agents and insecticides is discussed. It is not injurious to the skin or textiles, has a marked cleansing action, is a good solvent for many org. compds., mineral oils, fatty oils, etc., and is reasonably cheap. C. J. WEST

Flow meters in the accounting of process steam (TALER) 1. Apparatus for extracting oils from animal or vegetable materials (Brit. pat. 232,601) 1.

Mixed glycerides of lower and higher fatty acids. G. I. SCHWARTZ. U. S. 1,558,299, Oct. 20. Glycerides of fatty acids, *e. g.*, coconut oil, are heated with concd. HOAc in the presence of an esterification catalyst, *e. g.*, H₂SO₄, until a desired proportion of higher fatty acid radicals in the glycerides has been replaced by acetic radicals. Glycerol is then added and the mixt. is heated until a crude acetin mixt. is formed. Excess HOAc is distd. off and the mixt. is then heated further to a temp. above 150° but below that at which thermal decomn. of the glycerides occurs, N or other inert gas is passed through the mixt. to remove H₂O as formed, until esterification of the higher fatty acid by the acetin is practically complete. The product formed is adapted for softening pyroxylin compns.

Removing free sulfur from grease. H. CHRISTISON and C. L. NUTTING. U. S. 1,561,911, Nov. 17. Grease, *e. g.*, that from raw wool, is heated and agitated with an aq. soln. of a neutral alkali sulfite in sufficient quantity to convert the free S into thiosulfate and the aq. soln. contg. the thiosulfate is sepd.

Extracting oils from blubber. K. HOLTER and S. THUNE. Brit. 232,954, April 22, 1924. See Norw. 40,903 (*C. A.* 19, 1504).

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

The campaign of 1924-25 in Moravia. ALEŠ LINSBAUER. *Z. Zuckerind. Cechoslow. Rep.*, 49, 495-502, 502-8(1925); *Listy Cukrovar.* 43, 531 ff (1924-5).—Av. figures from 30 factories are: kg. chips per hl. diffuser, 55.4; diffusing time for 16-cell battery, 101 min.; draft, 111.2%; pressed pulp, 64.4%; total CaO to carbonation, 2.3%; raw sugar produced, 17.02%; molasses produced, 1.24%; coal consumption, 7.02%. All percentages are on beets. Brix (a), polarization (b), purity (c), and alky. (d) were: Pulp, (b) 0.29; battery waste water, (b) 0.10; raw juice, (a) 17.10, (b) 15.48, (c) 90.5; thin juice, (a) 15.61, (b) 14.60, (c) 93.5, (d) 0.010; thick juice, (a) 60.25, (b) 57.20, (c) 94.9, (d) 0.045; 1st fillmass, (a) 93.58; (b) 86.9; (c) 92.8; 1st sugar, (b) 94.85; 1st green sirup, (c) 86.87; 2nd fillmass, (a) 92.96, (b) 71.94, (c) 77.3; 2nd sugar, (b) 93.25; molasses, (a) 82.0, (b) 53.4, (c) 65.1. Sixteen mills used triple satn.; the rest, double. Alky. of 1st carbonation juice was 0.06%. One mill, by only washing press cakes to 17.6% sugar, obtained a thin juice of 19.6° Bx. Only 5 mills had to clean evaporators during the campaign, and these cleaned only once. Av. losses were: known, 0.42%; unknown, 0.45%; total 0.87%. The av. no. of employees were 48 per 100 metric tons beets per day. W. L. BADGER

Proposals for decreasing steam consumption, in beet sugar factories, for heating, evaporating and boiling; with an appendix on the pressure evaporator station. GUSTAV GLASER *Z. Zuckerind. czechoslovak. Rep.* 50, 9-14, 21-4, 29 31(1925).—G. suggests a quintuple under pressure, with steam, to the 1st effect at 135° (3.2 atm. abs. or 30 lbs. gage), boiling points of 130°, 125°, 118°, 110°, followed by a pre-cooker boiling at 90°. Battery heating is to be accomplished by direct injection of vapors from the 2nd effect; raw juice is to be heated to 50° by vapors from the pans, and to 80° by hot evaporator condensate in heat interchangers. Thin juice is to be heated to 95° by vapors from the 4th effect, to 110° by vapors from the 3rd effect, to 125° with vapors from the 1st effect, and to 130° with exhaust steam. Raw sugar pans are to be heated by vapors from the 1st effect; 2nd product pans by vapors from the 4th. Full details of calcons. are given for this case (I) and one similar except for juice consens. at certain points (II). A 3rd calcn. (III) is made for a triple under pressure, heated by steam at 123° (17 lbs. gage), the 1st effect boiling at 118° and heating the 2nd thin juice heater, 2nd effect boiling at 112° and heating the 1st thin juice heater, carbonated juice heater, juice boiler and 1st pan; the 3rd effect boiling at 102° and heating the 3rd thin juice heater, the 2nd carbonation heater, the 1st and 2nd pans. This represents the best practice at present with pressure evapn. The final results for total steam consumed are: quadruple effect under vacuum, 47.8-43.1 kg. steam per 100 kg. beets; same with juice boiler, 47.2-43.4 kg.; case (III) 38.06 kg.; case (I), 26.46 kg.; case (II) 24.48 kg.

W. L. BADGER

Velocity of solution of refined sugar. K. J. SMOLENSKI. *Gazeta Chemiczna* 1924, 19 22; *Centr. Zuckerind.* 33, 1195(1925).—Samples of various kinds of pressed refined sugar were shaken with 50% EtOH. The soln. was removed every 5 min. and polarized, and fresh soln. added. The amt. dissolved per 5 min. increased at first (as pore spaces became larger), then decreased (as total surface decreased). Expts. on single large crystals whose surface was measured confirmed the expression $K = (1/t) \log_e [C/(C-X)]$, where t is time, s is surface of crystal, C = concn. of satd. soln., and X is concn. of soln. surrounding the crystal. Crystals running 1114 per g. dissolved at continuously decreasing rates, as pore space was ample and surface was the detg. factor. Crystals running 29,900 per g. dissolved at an increasing rate as pore space increased, then at a decreasing rate as surface decreased.

W. L. BADGER

Use of ultra-violet light for determining the quality of commercial sugar products. HARALD LUNDÉN. *Centr. Zuckerind.* 33, 1281-2(1925).—The colors present in sugar solns. absorb violet strongly, and are best compared in ultra-violet light. If blue has been used on the sugar, it is almost impossible to compare colors in daylight. If the absorption shown by the coloring matter of sugar be called 1.00 for light of 6450 Ångström Units, for wave length 6050 it is 1.5; for 5200, 3.0; and for 4300, 5.0. Sugar samples, compared in the light of a quartz Hg-vapor lamp screened by Uviol glass, could be evaluated very accurately. Refined sugar with an ash (a) of 0.0007% gave a relative color (b) of 0.1; refined sugar, (a) 0.003, (b) 1.0; loaf sugar, (a) 0.010, (b) 1.5; affined sugar, (a) 0.07, (b) 12.0.

W. L. BADGER

Spectrophotometric investigations of sugar colors in a refinery. HARALD LUNDÉN. *Centr. Zuckerind.* 33, 1311 2(1925).—The laws of Lambert (absorption proportional to thickness of layer of soln.) and of Beer (absorption proportional to concn.) were confirmed for sugar solns. Absorption spectra for different beet products gave the following av. results. (a) = wave length in Å. U., (b) = "extinction coeff." or reciprocal of thickness of layer necessary to cause the same relative absorption. (a) 7000, (b) 0.08; (a) 6000, (b) 0.28; (a) 5500, (b) 0.33; (a) 5000, (b) 0.55; (a) 4500, (b) 0.90; (a) 4300, (b) 1.0. There was no definite max. or min. in the absorption spectrum. Changes in alkyl. did not change the shape of the curve, affecting the absolute values only. Affined Java sugar in a 50° Bx soln. at $p_H = 10$ gave figures checking Zerbán (*Sugar* 27, 266(1925)) showing a min. absorption in the yellow.

W. L. BADGER

First results with (cane) varieties 2878 and 2883 POJ. J. KUYPER. *Arth. Suikerind.* 33, 901-5(1925). These new varieties have in many tests proven superior to the best present varieties and are worthy of further study.

F. W. ZERBAN

The borer pest (in Java). III. J. POLL. *Arch. Suikerind.* 33, 699-702(1925).—Reply to van Harreveld (*C.* 1, 19, 3169). IV. *Ibid* 857-66.

F. W. ZERBAN

Fruit sugar of Rouen, genuine and artificial. G. A. LEROY. *Bull. sci. pharmacol.* 32, 527-44(1925).—The paper is mainly historical. The points emphasized in distinguishing made up and adulterated sugars from the genuine are: the presence of dextrin and CaSO₄ from the com. glucose used in the artificial or adulterated product, and the ratio of glucose to levulose. At present the problem is not solved completely.

L. W. RIGGS

The behavior of raffinose in the crystallizing operations. RICHARD MEHRLE. *Deut. Zuckerind.* **50**, 1325-8, 1357-61(1925).—Careful analyses made during 2 campaigns have shown that the proportions between the different non-sucrose substances vary widely in different products, even between a fillmass and the crystals and runoff obtained from it. In crystals of high purity the non-sucrose consists of about 45-50% each of raffinose and org., and 5-10% ash. The relationships between the compn of a fillmass, and of the crystals and runoff resulting by purging are shown in a graph. From such a graph the quantity of runoff and crystals in a given raw sugar for a given rendement can be found or else the yield of crystals can be calcd. from the crystal content of a fillmass and the crystal content of the sugar. During crystal formation a certain proportion of raffinose and of ash is deposited in the crystal, while the org accumulates more on the outer surface of the crystal. By following the raffinose throughout the raw sugar process, it was found that with falling true purity of the product the ratio between raffinose and sucrose increases gradually, while that between raffinose and non-sucrose decreases, at first rapidly and then more slowly. These relationships are shown in a graph. The ratio between raffinose and sucrose in a sugar is generally about one-third of that in the fillmass from which it is obtained. During the 1st half of the campaign this ratio was 0.46, during the 2nd half 0.22. No such more or less const. ratios could be found for ash and org. On the basis of the regularity in the raffinose ratios the distribution of raffinose between sugar and runoff can be calcd. for a given fillmass. Four examples are cited and discussed in detail. In refinery operation the raffinose content of the raw sugar has a pronounced effect on the sugar yield, as is shown in 3 examples. G. SCHECKER. *Ibid* 1413.—Analyses of unwashed and washed sugar (high- and low-grade raw sugar, low-grade sugar from degumization plant at Dessau) have shown the washed crystals to be free from raffinose. Raffinose crystallizes together with sucrose only from high purity fillmasses. M.'s results are due to faulty methods of analysis. RICHARD MEHRLE. *Ibid* 1445.—The differences between S.'s and M.'s results are probably due to differences in raw material and mfg. conditions. F. W. ZERBAN

The absorption of lime from sugar solutions by boneblack. JAROSLAV DĚDEK AND O. LANGER. *Z. Zuckerind. czechoslovak. Rep.* **50**, 1-8(1925); *Listy Cukrovar.* **43**, 301 ff. (1924-5).—A no. of solns of affined sugar were made alk. with CaO and treated with varying amts. of boneblack. Full data are given. CaO is selectively adsorbed. This adsorption cannot go far enough to make the soln. neutral to methyl red; hence there can be no danger of inversion and liquors to be filtered through boneblack need not be limed. Omitting CaO treatment of the liquors makes regeneration of the black easier. W. L. BADGER

Alkalinity and color (of sugar solutions). BRUNOLF BRUKNER. *Centr. Zuckerind.* **33**, 1066(1925).—Graham has shown that caramel is flocculated by acids and peptized by alkalis. Hence Lundén's "new" color (C. A. **19**, 2278) is probably caramel. The differences in the p_H at which it is pptd. in beet and cane sirups are probably due to the presence or absence of protective colloids. LUNDÉN. *Ibid* 1117.—The curve obtained by varying the p_H of the soln. shows that a true indicator is present, not caramel. W. L. BADGER

Comparison of filterpresses with thin and thick cakes. A. GRILL. *Centr. Zuckerind.* **33**, 963-5(1925).—A press 815 × 815 mm. (approx. 30 × 30 in.) with 35 frames 25 mm. thick will filter the juice from 132,500 kg. beets per 24 hrs. This calls for a rate of filtration of 4.02 l. per min. per sq. m. (5.9 gal. per sq. ft. per hr.) and 16.2 cycles per 24 hrs. Each cycle consists of 49 min. filtering, 30 min. for washing, and 10 min. for opening and closing. Assuming that with a 50 mm. cake the rate of filtration will fall to 3.0 l. (4.4 gal.) it is calcd. that a press with 76 frames 50 mm. thick will correspond to 257,000 kg. beets. For a 1200-ton mill there will be needed 9 small presses or 5 large ones. The large presses will have 26% more filtering surface, but because of their longer cycle will have to be opened half as many times per day, will use only 50% of the labor, and, because of the fewer cycles, will be less hard on cloths. Hence larger presses are to be chosen in preference to small ones. W. L. BADGER

An unusual disturbance in the evaporator station. VIKTOR SPONDR AND ALEXANDER PLATZER. *Z. Zuckerind. czechoslovak. Rep.* **50**, 46-8(1925).—During the campaign the evaporator tubes became completely filled with a dark-brown ppt. which appeared very rapidly. It was finally found to be a mixt. of Ca and Mg soaps and oxalates. The limestone used carried 5% MgCO₃. The MgO combined with the fats used to prevent foam, and formed a bulky ppt. which occluded much sugar and all kinds of suspended material. A sample of the fat used, saponified with MgO and boiled with thick juice, gave no ppt.; but on adding a few crystals of oxalic acid, a ppt. formed

immediately, exactly like the one found in the evaporators. Hence an unusual concn. of oxalates was held to be the immediate cause. W. L. BADGER

Advantages of drum driers as compared to "wender" driers. KARL FÄHMEL. *Centr. Zuckerind.* 33, 1064-6(1925).—A 63-hour test on a Büttner drier 2.6 m. diam. \times 13 m. long showed a production of 290 metric tons dry chips of 16.3% H_2O from wet chips of 86.7% H_2O , with 135 tons coal of 6900 cal. per kg. (12,400 B. t. u. per lb.). A total of 55 elec. h. p. was used. W. L. BADGER

The blueing of crystals in the centrifuge. BERTHOLD BLOCK. *Deut. Zuckerind.* 50, 1301-3(1925).—Both ultramarine and indanthrene are used. Indanthrene is insol. in H_2O , is not decompd. by acids or alkali, is harmless to the human system, and contains neither Sn or As. Either may be added to the pan in boiling sugar, but both are best used by spraying into the centrifugal after washing. A no. of patented devices for spraying blue are described. W. L. BADGER

Some analyses of commercial corn sirups. C. P. LATHROP. *J. Assoc. Official Agr. Chem.* 8, 714 5(1925).—Analysis of 9 samples of com. corn sirups gave the following av. values: Baumé 43.30°, solids by refractometer 82.25%, solids by drying *in vacuo* at 70° 81.05%; sugars as glucose (by Cu), before inversion 35.65%, after inversion 36.38%, after boiling 2½ hrs with dil. HCl 81.40%; total ash 0.321%, alk. no. of ash 11.5, S in ash 3.31%, P_2O_5 in ash 23.4 mg. per 100 g., K_2O in ash 2.04%, Cl in ash 22.05%, acidity 6.1 cc. 0.1 N acid; polarization of N soln., before inversion 20° +171.4°, after inversion 20° +169.4°, after inversion 87° +159.0°; com. glucose (factor 163) 97.50%, com. glucose solids (factor 196.17) 81.05%. The refractometer method gave uniformly slightly higher results than drying *in vacuo* at 70°. A. P.-C.

Polarization results on molasses from the last campaign, clarified with alkaline lead nitrate and with basic lead acetate. R. OFNER. *Z. Zuckerind. czechoslov. Rep.* 50, 38-9(1925); cf. Weiss, *C. A.* 19, 3029, 3612.—Nineteen samples using half-normal wt. gave an av. reading 0.213% higher using basic Pb (OAc)₂, with a max. of 0.5%. Twenty samples using normal wt. gave an av. reading 0.165% higher, with a max. of 0.4%. Samples kept a long time seemed to show less difference. Out of the 39 samples, 7 showed no difference. W. L. BADGER

The gasification of molasses residues and the recovery of potash, sodium cyanide and ammonium sulfate. F. MUHLERT. *Chem. App.* 12, 156-7, 189-91, 211-3(1925); 9 cuts.—Descriptions of plant, directions for operating, and data on yields. J. H. MOORE

Saponification value of starches. L. ROSENTHALER. *Pharm. Zentralhalle* 66, 631(1925).—The following values were obtained by heating 1 g. of the sample for 1 hr. with 20 g. 1%OH and 5 cc. of 0.1 N alc. alkali in connection with a reflux, thereupon titrating the unexpended alkali with 0.1 N acid to a permanently colorless soln.: wheat starch 5.1, rice 4.9, maranta 3.3 potato 4.7, corn 3.2, sago 5.3. It is believed these figures are true sapon. values depending on the sapon. of amylopectin, an ester of H_3PO_4 . W. O. E.

Composition of sugar beet pulp and top and of silage therefrom (SHERWOOD) 12. **Sugar-dust explosions (SANDTNER)** 24.

Sugar from beets. I. DE VECCHIS. U. S. 1,562,151, Nov. 17. Cossets are heated to a temp. sufficient to dry and sterilize them and the dried cossets are lixivated to obtain a highly concd., almost neutral sugar juice. Lime is added to the juice to render it alk. and to ppt. the less complex dissolved albuminoids. Ca superphosphate is added to the juice to neutralize it and it is then filtered.

Glucose. CORN PRODUCTS REFINING CO. and W. B. NEWKIRK. *Brit.* 232,938, April 25, 1924. Details are specified for treating glucose solns. to obtain a cryst. product (cf. *C. A.* 19, 2756).

Drying dextrose. CORN PRODUCTS REFINING CO. and J. J. MERRILL. *Brit.* 232,584, April 18, 1924. Cryst. dextrose or similar pulverulent material is dried while being passed through inclined horizontal rotary cylinders, by hot air or gas.

29—LEATHER AND GLUE

ALLEN ROGERS

Leather work at the Bureau of Standards. R. C. BOWKER. *Leather Mfr.* 36, 231-6(1925).—Descriptions of the Bureau's research equipment, types of problems being investigated and some of the results. J. A. WILSON

The need and use of analyses of the raw and prepared materials of the leather industry. R. LAUFFMANN. *Ledertech. Rundschau* 17, 121-3(1925). I. D. C.

Testing the serviceability of leather. P. PAVLOVICH. *Collegium* 1925, 455-65.—The work of Hart and Bowker (*Bur. Standards, Tech. Paper, No. 147*) and others is reviewed. Bobarikoff and Malischeff used a cement tester in which the leather pieces were moved in a circle in a large body of sand of a definite size. P. devised an app. in which 2 samples on a wheel rotate against a steel rasp. He found that fats increase the wear of leather greatly, that the side is weaker than the back and that the wear per unit thickness is greater than that per unit weight. I. D. C.

Increasing the wear of sole leather. R. C. BOWKER. *Hide & Leather* 70, No. 18, 90-4; No. 20, 51; No. 21, 42-3(1925).—The wear of sole leather can be increased by raising its grease content and by rendering it more flexible. Chrome-tanned soles wear twice as long as vegetable-tanned soles, but have the disadvantage of poorer appearance and lack of firmness and of water resistance. J. A. WILSON

Spueing and dulling in shoe leathers. D. WOODROFFE. *Leather World* 17, 830-4 (1925).—The appearance of spue on the surface of leather after chilling may be due to excessive amounts of solid fatty acids, natural skin greases, chrome soaps, or salts. J. A. WILSON

The hydrolysis of vegetable-tanned leather. HEINRICH ROSE. *Collegium* 1925, 465-79.—A no. of leathers were leached with cold and with boiling H_2O until the ext. gave no test with Fe alum. in each case and then analyzed. Leaching at ordinary temp. removed mostly tannin and nontannin while boiling H_2O dissolved also considerable hide substance. The extd leathers had a nearly const. compn., averaging 78 parts of tannin per 100 parts of hide substance. The course of the hydrolysis at the beginning depends on the manner of tanning. I. D. C.

The use of fish oil in the leather industry. A. BRESSER. *Ledertech. Rundschau* 17, 155-6(1925).—A brief review. I. D. C.

White chrome leather. H. SALT. *Leather World* 17, 770-6(1925).—Details of expts. leading to the production of white leather by means of the 2-bath tanning. J. A. WILSON

Spots on glove leather. P. HUC. *Halle aux cuirs* 1925, 298-9.—Spots on glove leather were traced to emery particles deposited during shaving, which reacted with H_2SO_4 in the skin to form $FeSO_4$. H. B. MERRILL

Artificial leather. KARL MICKSCH. *Kunststoffe* 14, 120-2(1924).—General review. C. J. WEST

Technic of chamois manufacture. RIGOLLET. *Ganterie; Halle aux cuirs* 1925, 300-7.—A description. H. B. MERRILL

Report to the special meeting of the Union of Academic Chemists at Darmstadt, July, 1925. E. STIASNY. *Ledertech. Rundschau* 17, 113-6, 123-6(1925).—An address reviewing the use of $ZnCl_2$ to produce sterile soaks, Cr tanning with complex compds., oil analysis and recent developments in soaking, bating and vegetable tanning. I. D. CLARKE

New tanning materials and tannery sundries. LEOPOLD POLLAK. *Gerber* 51, 157(1925); cf. *C. A.* 20, 123.—Analytical data are given for certain com. brands of $HCOOH$, $CaCl_2$ and "Calcin." The latter is a 20% soln. of $Ca(SiH)_2$. H. B. M.

Sulfite cellulose extract for tanning. WALTER PETRIE. *Leather World* 17, 680-2 (1925).—Suggestions for the use of waste sulfite cellulose as a valuable tanning agent in conjunction with catechol tannins or with gum tragacanth. J. A. WILSON

South American quebracho extract. WILHELM VOGEL. *Ledertech. Rundschau* 17, 116-9(1925); cf. *C. A.* 19, 3034.—Production and prices are discussed. I. D. CLARKE

The reactions of pure, sulfited and cellulose extract-containing quebracho extracts. ANON. *Collegium* 1925, 438-55; cf. *C. A.* 18, 2822.—Mixts. of quebracho and 3 cellulose exts. were analyzed and tested qualitatively. The gelatin-salt test became somewhat less sensitive and the Br_2 test rapidly less sensitive as the amt. of cellulose ext. was increased. The ratio of tannin to nontannin was decreased from 9 or 10 to 3:4 by the addn. of 20% of cellulose ext. The increase in amt. of insolubles with increasing concn. was greater if cellulose ext. was present. I. D. C.

Analysis of used chrome liquors. F. KLINGER. *Collegium* 1925, 525-6.—Oxidation of used Cr liquors with Na_2O_2 gives reliable results if, after the first boiling, more Na_2O_2 is added to decompose CaO_2 . The method is described in detail. I. D. C.

The soak and white weight. J. E. WEISSBERG. *Collegium* 1925, 522-5.—After soaking and draining 2 hrs. raw skins had the same wt. as in the green condition. W. suggests taking the white wt. at the isoelec. point (p_H 5.5) after draining 2 hrs. I. D. C.

Recent progress in the glue and gelatin industries. HERMANN STADLINGER. *Kunststoffe* 14, 97-8(1924). C. J. WEST

Manufacture of linoleum, artificial leather, etc. (SCHWARZ) 26. Modified casein [for sizing leather] (U. S. pat. 1,551,471) 18. Apparatus for extracting gelatin from animal or vegetable materials (Brit. pat. 232,601) 1.

Tanning fish skins. A. EHRENREICH and K. BENDIXEN. Brit. 231,084, Dec. 18, 1923. Preparatory to tanning, fish skins are milled, at a temp. of about 30°, in a bath contg. about $\frac{1}{2}$ —1 part lactic or acetic acid or equiv. acid, about 3 parts NaHSO₄ and H₂O, with or without a mordant such as "oropon." This treatment expedites the subsequent tanning treatment.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Researches on the nature of matured rubber (slabs). G. BRUNI AND T. G. LEVI. *Giorn. chim. ind. applicata* 7, 447-51(1925).—Detn. of the acidity of several types of raw rubber by the method of Whitby (*C. A.* 17, 3808; 19, 907), except for the replacement of Me₂CO by abs. EtOH, gave results which agreed well with those of W. On the other hand matured rubber (coagulated with HOAc, pressed and dried to 20-5% H₂O) without preliminary washing and drying had an acidity approx. 3 times (dry wt.) that of smoked sheets. By washing this matured rubber with cold H₂O or by heating it *in vacuo* at 130° its acidity was reduced from its original extremely high value to that of other types. Washing or distn. *in vacuo* did not, however, influence materially the time to reach a given state of cure when vulcanized with S alone, but after extn. with Me₂CO or abs. EtOH the time of cure was increased nearly 5-fold, the extd. rubber curing at approx. the same rate as smoked sheet. From the distillate at 130° *in vacuo* were obtained NH₃, volatile satd. fatty acids among which HOAc predominated and also homologous acids such as valeric acid. A valeramide (probably *n*-C₄H₉CONH₂) was present in the highest fraction and the acids in the rubber were probably present in the form of amides or NH₄ salts. It was found that both *n*-C₄H₉CONH₂ and *iso*-C₄H₉CONH₂ are accelerators and when 3% of either is added to a rubber-S mixt. the time of vulcanization is reduced to approx. $\frac{1}{3}$ and $\frac{1}{2}$ its values, resp. The Me₂CO ext. of the matured rubber contained a mixt. of higher fatty acids which were obtained sep. from the composite ext. by extg. the undried rubber in thin sheets rolled with Pb foil. Under these conditions a mixt. of Pb stearate and palmitate was obtained, from which the free acids were isolated in almost equal amts. of 0.5-0.7% based on the crude rubber. Though the time of cure of matured rubber was increased about 5-fold by extn. with Me₂CO, by returning this ext. (after drying at 70°) to the rubber its normal rate of cure was practically restored. Furthermore addn. of this ext. to first latex crepe increased its rate of cure 4-fold, rendering it capable of curing in only twice the time of unextd. matured rubber. The Me₂CO ext. was completely sol. in a mixt. of H₂O and Et₂O, the Et₂O absorbing 90% of the total. The Et₂O fraction was composed chiefly of higher fatty acids which had only a very slight accelerating action, judged by their addn. to first latex crepe. The H₂O fraction contained 9.27% N and was a very active accelerator, indicating that the natural accelerators contain N and comprise the aq. portion of the Me₂CO ext., though they cannot be extd. directly from the crude rubber with H₂O. The work involved the detn. of the *m. p.* of *palmitanilide* and of *stearanilide*, which were 88-90.5° and 94°, resp., compared with 90.4° and 93.6° recorded in the literature. C. C. DAVIS

Chemical and physical methods and their importance in rubber research. F. KIRCHHOFF. *Gummi-Ztg.* 40, 93-4(1925).—A review of the role which physics and chemistry have played in the study of the properties of latex and raw rubber. Phys. and colloid-chem. methods now offer more promising means of studying the structure of rubber than the purely chem. methods relied upon to so great an extent in the past. C. C. DAVIS

The physical properties of rubber. Microscopic examination of rubber. L. B. SEBRELL, C. R. PARK AND S. M. MARTIN, JR. *Ind. Eng. Chem.* 17, 1173-6(1925).—A photomicrographic study, in some cases by motion pictures, of the changes taking place in latex when it is coagulated or dried and in the dispersion of the coagulum in org. solvents has confirmed the work of previous investigators relative to the shape of latex

particles and their persistence after coagulation. When latex is coagulated or dried, the globules do not lose their identity and the resulting rubber appears to be composed of a very closely packed mass of discrete globules. This structure will account for various phenomena before and after vulcanization, as examples of which it is suggested that the increase in plasticity of rubber when milled and the lower viscosity of cements made of masticated rubber are due to partial destruction of these intact globules.

C. C. DAVIS

The structure of rubber. I. PAUL BARY. *Rev. gén. caoutchouc* 3, 225-30(1925).—A survey and crit. discussion of the spheroidal and the isocolloidal hypotheses of the structure of rubber and recent work to explain calender grain. Twenty-two references are included.

C. C. DAVIS

Measurement of crude rubber consistency. D. F. CRANOR, *et al.* *Ind. Eng. Chem.* 17, 1202(1925); cf. *C. A.* 19, 2575.—The tentative method proposed by the Crude Rubber Comm. (Rubber Div., Am. Chem. Soc.) as a criterion of the consistency of raw rubber is described. The sample of rubber, with as little preliminary mastication as practicable, is tested in a Williams plastometer (cf. *C. A.* 18, 1763) with the whole system in equilibrium at 100°.

C. C. DAVIS

The plasticity of rubber. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* 21, 12345-7, 12461-3(1924); 22, 12622-3, 12710, 12812-3(1925).—A review of the work of Williams, Krall, Beebe and Stringfield, Marzetti and de Vries.

C. C. DAVIS

Relation between dye adsorption of clays and their behavior in rubber compounds. H. R. THIES. *Ind. Eng. Chem.* 17, 1165-9(1925).—The great differences in the way that clays influence both the rate of vulcanization of a given rubber mixt. and its max. tensile strength cannot be correlated with the chem. compn. of the clays nor with impurities which they may contain. On the other hand where clays of similar chem. compn. behave differently in rubber this unlike behavior is accompanied by an unequal power of adsorbing dyes from soln. In general the more favorable the action of the clay in rubber, the less dye it adsorbs. To foretell the influence of a clay in a vulcanized rubber mixt. 2 g. of clay is agitated with 50 cc. of 0.1% malachite green soln. and the amt. of adsorption detd. in a Dubosc colorimeter by the color of the supernatant liquid. The parallelism between the capacity of a clay for adsorbing dyes and its behavior in rubber is most marked when org. accelerators are present in the rubber, and is in fact very little in unaccelerated rubber mixts., suggesting that possibly the influence is due to adsorption of the accelerator by the clay. Contrary to Arrhenius (cf. *C. A.* 16, 1350) there is among various dyes no relation between the quantity adsorbed by a given clay and the mol. wt. of the dye.

Synthetic preparation of rubber and the higher alcohols. A. DUBOSC. *Kunststoffe* 15, 33-4, 112-3; *Caoutchouc & gutta-percha* 22, 12585-6(1925).

C. J. WEST

Wearing qualities of tire treads as influenced by reclaimed rubber. W. L. HOLT AND P. L. WORMLEY. *Bur. Standards, Tech. Paper No. 294*, 579-88(1925).—Service tests to det. the comparative resistance to wear of tread compds. contg. reclaimed rubber and those with new rubber alone were made by constructing tires in sections, each of the latter representing a compd. under test. Comparative tests were made in turn between these service tests and lab. abrasion tests by various methods. The results indicate that the resistance to wear is a max. when no reclaimed rubber is present and that the substitution of reclaimed for new rubber reduces the resistance to wear roughly in proportion to the amt. of reclaimed rubber used. Even with 25% reclaimed rubber by wt., however, a tread can be made which will wear 70% as long as one contg. new rubber alone. Six lab. abrasion machines gave results which agreed closely in all but one case with the service tests.

C. C. DAVIS

Formulas of mixtures. RUDOLF DITMAR. *Caoutchouc & gutta-percha* 22, 12861-5(1925).—Formulas of rubber cable and conduit insulating compds. are given.

C. C. DAVIS

Fatty acids in the acetone extract of Hevea rubber. P. DEKKER. *India Rubber J.* 70, 815-8(1925).—The Me_2CO ext. of *Hevea* rubbers was analyzed systematically by extn. of the Me_2CO ext. with H_2O , sapon. of the part of the Me_2CO ext. insol. in H_2O with Barfoed's alc. Na_2CO_3 , sepn. of the resulting H_2O -sol. fatty acids and of the H_2O -insol. solid and liquid fatty acids by Twitchell's method, sapon. with alc. KOH of the part unsaponifiable by Na_2CO_3 and sepn. of the resulting H_2O -sol. fatty acid of the mixt. of solid and liquid fatty acids and of the unsaponifiable residue. The H_2O ext. of the original Me_2CO contained HCO_2H , H_2O -sol. acids of the caproic-caprylic series and what was probably butyric acid, but no sugars. After sapon. with Na_2CO_3 HCO_2H , butyric acid, an acid of the caproic-caprylic series, oleic, linolic, stearic and probably palmitic acids were identified. A free phytosterol was present in the un-

saponifiable part. On sapon. of the latter part with KOH, HCO_2H , an acid of the caproic-caprylic series, oleic, linolic and stearic acids were obtained. The Me_2CO ext. of rubber, therefore, contains free oleic, linolic and stearic acids and probably palmitic acid, besides esters of all these acids. HCO_2H , butyric acid and acids of the caproic-caprylic series are also present, though all these lower acids may be formed during the Me_2CO extn., or subsequent boiling with H_2O , by partial decompn. of the esters of higher fatty acids. Insofar as the work coincides with that of Whithy (cf. *C. A.* 17, 3808; 18, 1589; 19, 907, 1963) the results are in agreement. C. C. DAVIS

Sodium fluosilicate for coagulating latex. H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 555-60 (1925); cf. *C. A.* 19, 1638.—It is recommended to coagulate the latex, contg. NaHSO_3 if desired and dild. to 1.5 lb. rubber per gal., by running it into a tank contg. 1 lb. dry Na_2SiF_6 per 150 gals. of latex and stirring for 30-45 min. Manufacturers report that Na_2SiF_6 -rubber behaves normally on the machines and that the rate of cure and tensile strength are also normal in mixts. contg. org. or inorg. accelerators. It cures slowly in rubber-S mixts. F. H. YORSTON

Toxicity of solvents for rubber, resins and cellulose esters. A. KOHN-ABREST *Kunststoffe* 14, 101-2 (1924); *Chem. Age* 32, 199-201 (1924).—See *C. A.* 18, 1921.

C. J. WEST

A deviation from the law of Poiseuille. BRUNO MARZETTI. *Rend. accad. Lincei* 2, [6a], ii, No. 5-6 (Sept., 1925).—It has already been shown (*C. A.* 18, 3738) that rubber does not conform to the law of Poiseuille over a considerable range of pressures. Since this deviation may be due to disturbing influences similar to those in other plastics, the attempt was made to det. the possible transition at high pressures from the law of squares to that of Poiseuille. Up to 50 kg. per cm^2 . and a flow of several m. per min., however, no approach to the latter law was found. As evidence on the transition between the abnormal behavior of rubber and the normal behavior of other plastics, comparative expts. on 2 solns. of rubber in C_6H_6 (1:4 and 1:2.34, resp.) showed that in the first case the flow varied directly with the pressure, whereas with the more concd. soln. the flow varied with the square of the pressure or even more rapidly. Likewise expts. on castor oil and on a mixt. (of the same viscosity) of rubber in heavy mineral oil (1:2.15) showed that the former followed the law of Poiseuille, but that with rubber-oil the flow varied directly with the pressure only at very low pressures and that above this range the flow increased more rapidly so that at length it varied with the square of the pressure. With mixts. more concd. in rubber (1:1.43) the flow finally increased more rapidly than even the square of the pressure. The transition from the law of Poiseuille to that of the square of the pressure is such that the less the mobility the sooner it appears, this transition range of pressures with rubber being so small that it could not be detd. The peculiar behavior of rubber, whether pure or dild. with other substances, is probably not due to the same causes which make other plastics deviate from the law of Poiseuille, for with the latter materials the causes are active only at low pressures, whereas with rubber the opposite occurs. Telescopic flow occurs in all cases, rubber included, and to explain the phenomena it is assumed that rubber has a property unknown among other substances, viz., a variable mobility (cf. *C. A.* 18, 3738), which at first remains const., then increases and remains over a wide range proportional to the square root of the velocity of flow and eventually increases still more rapidly. It remains to be explained why the variations in mobility are not more nearly continuous so that both the law of Poiseuille and that of the square of the pressure are valid only approx. for the particular range of pressure. C. C. DAVIS

New rubber softeners. RUDOLF DITMAR. *Gummi-Ztg.* 40, 94 (1925).—Esters of polyhydric alcs., such as acetin, diacetin, triacetin, α -dibutyrim, tributyrin, α -diolein, triolein and benzoins such as benzoinanilide (cf. Metzeler, German patent 411,539, Class 22i and A 42,958, Class 22i) are very effective softeners. A typical mixt. is rubber 100, trichloroethylene 2400, diacetin or triacetin 0.5. The adhesive powers of the solns. are increased by such small addns. Addn. products of terpenes and S are also good softeners. Superior to both groups of substances, however, are "solvol," "hexalim" and "heptalin," which are powerful softeners and give permanent dispersions. They increase the adhesive power of rubber solns., and may be mixed with the rubber when the latter is plasticized or may be added to the finished soln. C. C. DAVIS

Determination of rubber and inorganic materials in soft rubber goods. R. T. MEASE AND N. P. HANNA. *Kunststoffe* 15, 177-8 (1925), cf. *C. A.* 19, 1209.

C. J. WEST

The concentration of latex with the aid of the ultrafilter of Bechhold-König. RUDOLF DITMAR. *Caoutchouc & gutta-percha* 22, 12857-8 (1925).—The Bechhold-König ultrafilter (cf. *C. A.* 18, 2981) is well suited for filtering and thus concg. latex.

Addn. of protective colloids as in the Hauser process (cf. German patent 412,060) is unnecessary and concns. of rubber in the paste higher than 88% set by Hauser can be obtained.

C. C. DAVIS

C. J. WEST

Table of new methods for the precipitation of rubber latex. S. HALEN. *Kunststoffe* 14, 117-8(1924).—Thirty patents are listed(cf. *C. A.* 19, 1065).

C. J. WEST

The influence of moderate, prolonged heating on the trend of the stress-strain curve of vulcanizates which have been prepared with and without an accelerator. M. LE BLANC AND M. KRÖGER. *Gummi-Ztg.* 40, 25-6(1925).—When vulcanized rubber is heated at 80° its stress-strain curve shifts progressively in the same direction and in the same way that it does when the original vulcanization is prolonged a shorter but corresponding time. This is equally true whether the rubber is cured with S alone or with the aid of org. accelerators, though there is no invariable relation between the time of heating at a lower temp. and the extra time of vulcanization. Thus with a simple rubber-S mixt 24 hrs. at 80° is approx. equiv. to doubling the time of vulcanization at 135°, whereas with the same mixt. contg. an org. accelerator 24 hrs. at 80° gives an effect which resembles a much greater degree of over-vulcanization than does a two-fold time of cure. The latter fact emphasizes the danger in the use of excessive amts. of S in accelerated mixts. which are to undergo elevated temps in use.

C. C. DAVIS

Concavity factor of the stress-strain curve. T. R. DAWSON. *India Rubber J.* 70, 702(1925).—The formula of Wiegand for the concavity factor is incorrect in the form $C = [24 Ey/(TP)] \times 100$ as first published (cf. *C. A.* 19, 2423; *India Rubber J.* 70, 223(1925)), and should be $C = 24 Ey/(TP)$.

C. C. DAVIS

Formic acid as a coagulant for Hevea latex. O. DE VRIES, W. SPOON AND R. RIEBL. *Arch. Rubbercultuur* 9, 763-89(1925); (in English, *Ibid* 790-5).—A large no. of crepe and sheet samples prepd. with H_2CO_2 in the lab. and on estates had a slightly longer av. time of cure in rubber-S and $C_6H_{12}N_4$ mixts. (but not in a PbO mixt.), a lower viscosity and greater plasticity than controls prepd. with (usually) twice as much HOAc. The differences between the 2 types were, however, no greater than those found among HOAc samples. The properties of crude and vulcanized lots of each changed in the same way during storage for a yr. No slow-curing H_2CO_2 samples such as previously reported (*C. A.* 14, 3168), were found.

F. H. YORSTON

Formic acid as a coagulant. H. P. STEVENS. *Bull. Rubber Growers' Assn.* 7, 568-70(1925); cf. *C. A.* 19, 908.—Crepe and sheet samples prepd. with H_2CO_2 cured in most cases, a little more quickly than did HOAc-coagulated controls when tested in rubber-S and PbO mixts. and in a mixt. contg. ZnO and $(NHPh)_2C:NH$. Rubber coagulated with the min. amt. of H_2CO_2 cannot be distinguished from rubber coagulated with HOAc.

F. H. YORSTON

Theory of rubber vulcanization in hot air. B. V. BUTZOV. *J. Ind. Chem. (Russia)* 1, 14-7(Jan.-Feb., 1925).—The theory is held that vulcanization in hot air is due essentially to a chem. reaction which takes place between the acid resins of rubber and PbO . On heating resins, extd. from rubber by means of acetone, with PbO at 130°, chem. compds. were obtained which contained Pb and dissolved easily in cold $CHCl_3$. During the vulcanization of rubber the same Pb salts of resin acids are formed, which then react with rubber in some unknown way and become insol. in $CHCl_3$. PbS and $PbSO_4$ are formed in relatively small quantities and their formation plays a secondary role in vulcanization. The arguments in favor of this theory are as follows. (1) no rubber can be vulcanized in hot air without PbO , HgO or Ag_2O ; (2) rubbers which contain only small amts. of resins, or those which have been deprived of their resins by extn. do not vulcanize in hot air even in the presence of PbO ; (3) if the acid resins of rubbers are extd. and replaced by other suitable acids the rubbers can be vulcanized just as well as rubbers contg. resins, suitable acids being those which melt at the temp. of vulcanization and dissolve in rubber and (4) PbO can be replaced by basic salts of Pb , but not by acid salts, a fact which shows that the presence of the basic hydroxyl of Pb is necessary for the formation of salts with the organic acids present in rubber, though Pb salts of higher acids, such as Pb stearate, palmitate, oleate, have themselves a favorable influence on vulcanization. To confirm this theory, the acid nos. of various rubber resins and the abs. acidity of rubbers were detd., abs. acidity being the product of the % resins and the acid no. of the resins. The results were as follows, the data giving the % resin, the acid no. of the resin and the abs. acidity, resp.: Para 3, 98, 294; crepe 3-2, 45-93, 135-186; Ceara 4, 43, 172; Congo Kassai 4, 12, 48; guayule 20, 12, 240; Upper Congo 33.6, 12, 44; Benguela 6, 10, 60; Kassai 4, 8, 32; Peruvian 3, 6, 18;

Accva lumps 26, 2.9, 75.5. Of these rubbers, Para, crepe, Ceara, guayule and Accva lumps vulcanize in hot air without the addn. of resins or other acids, as they contain a high enough % of acids to effect a vulcanization by combining with PbO. The other rubbers do not vulcanize unless suitable acids are added. The min. abs. acidity necessary is between 75.5 and 60, since Accva lumps vulcanize and Benguella does not. All the expts. were carried out with mixes having the compn.: rubber 100, PbO 30, S 3, and the arguments above hold true only if these proportions are observed. With larger amts. of S even rubbers contg. very small amts. of resins can be vulcanized if PbO is present.

BERNARD NELSON

An attempt to explain the action of vulcanization accelerators. B. BYSOV. *India Rubber J.* 70, 859-60(1925).—Though accelerators always improve the phys. quality of rubber and increase the rate at which the rubber becomes insol in org. solvents, some do not increase the rate of addn. of S to rubber, and there is not necessarily any connection between the activity of an accelerator and its power of transferring S to rubber, as demanded by chem. theories of vulcanization. Vulcanization is the *formation of a colloidal system* where the dispersed phase is S in the form of supercooled droplets in a continuous phase of rubber (cf. *J. Russ. Chem. Soc.* 53, 1(1925)). *Chem. combination* is incidental, as proved by the Peachey cold process, where only the first phenomenon occurs, no S reacting chemically. Furthermore the 2 characteristics of vulcanization, *increased "elasticity"* and *decreased soly.*, can be brought about without S, e. g., with C black (cf. LeBlanc, Kroger and Klotz, *C. A.* 19, 3398). A similar change can be brought about by mixing AmOAc solns. of rubber and of FeCl₃ evapg. to a film, and treating with H₂S or NH₄OH. The ppt. of FeS or Fe(OH)₃ leads to the rubber properties simulating those of ordinary vulcanized rubber. Any substance in which rubber can swell is an accelerator and likewise any substance which is sol in rubber and in which S is sol. has an accelerating action, the latter being most favorable when rubber is more sol. in it than is the S. Furthermore any substance sol. in rubber and capable of forming a ppt. insol in rubber is an accelerator, and in general any *increase* (within certain limits) of the *internal surfaces sepg. the phases* involves acceleration of vulcanization. These criteria include *gaseous accelerators* such as H₂O vapor, NH₃, H₂S, HClHO, etc.

C. C. DAVIS

Oxidation products of aromatic thioureas as accelerators of vulcanization and the formation of "elastic sulfur." E. ROMANI AND C. PELIZZOLA. *Kunststoffe* 15, 156-7 (1925); cf. *C. A.* 19, 1966.

C. J. WEST

Modern compounding ingredients. I. Properties and use of a number of well-known rubber accelerators, softeners and pigments. J. M. BALL. *Rubber Age* 18, 92-4(1925).—A description of the *accelerating properties and uses of tetramethylthiuram disulfide and Pb dimethyldithiocarbamate*, which as com products are known as Tuads (I) and Super-sulfur No. 2(II). Besides the general accelerating properties of I which are already well known, expts. have shown that its accelerating activity is retarded by clay, C black and reclaimed rubber and is inhibited by MgO, Sb compds. and white factice. Unlike I, which requires ZnO as an activator, II is unique among org. accelerators in that it requires PbO for its max. activation. **Modern compounding ingredients. II.** *Ibid* 125-7.—A description of the manuf., properties and uses of "hard hydro carbon," "thermatomic C" and "Dixie clay."

No. 3

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Inexpensive autoclave for small laboratories. E. E. WOLFE. *J. Am. Water Works Assoc.* **14**, 357-8(1925).—Outlines the modification of a 25-qt. "Denver" pressure cooker to make it available for lab. service. D. K. FRENCH

A simple photometer attachment for ultra-violet absorption measurements. T. T. BAKER AND L. F. DAVIDSON. *J. Sci. Instruments* **3**, 13-5(1925). E. J. C.

A simple gas calorimeter. HARALD NIELSEN. *Gas J.* **171**, 107-9(1925).—The calorimeter body is a glass cylinder $2\frac{1}{4}$ to $2\frac{1}{2}$ in in diam by $11\frac{1}{2}$ to 12 in. long; the lower end is closed by a rubber stopper carrying a Cu tube $1\frac{1}{4} \times 7$ in. closed at one end in an inverted position as a combustion chamber. A wooden lid carries a thermometer graduated to $\frac{1}{20}^{\circ}$ and a stirrer. A small Bunsen burner with a sideall tube inserted inside to carry the gas to the top and a side tube at the bottom to form air passage in the outer compartment, and a spark gap at the top for gas ignition, burns the gas. Air is supplied to the burner by change of water level in two leveling bottles. The burner is connected to an inverted 1000-cc graduate for measuring the gas. The gas is drawn in and forced out of the graduate by means of liquid in two bottles connected to the graduate. The water charge of the calorimeter is 500 cc. Formulas and details are given A. E. GALLOWAY

A thermoregulator. H. J. WING AND T. J. THOMPSON. *Ind. Eng. Chem.* **17**, 1242 (1925).—The new app., like that of Davis and Pratt (*C. A.* **9**, 2470), utilizes Hg and PhMe, but has several advantages. C. C. DAVIS

Electric bath heater (immersion heater) for heating acid baths. ANON. *Apparatenbau* **37**, 314-5(1925).—One cut. J. H. MOORE

A heat flow meter and its use for measuring heat losses in steam lines. ARNOLD KORTING. *Gas u. Wasserfach.* **68**, 715(1925).—The meter consists of a thick strip of rubber into which are vulcanized a large no. of thermocouples. If this strip be wrapped around a pipe, the heat loss from which it is desired to det., the temp. difference between the inside and outside of the strip may be easily detd. and is proportional to the heat loss from the pipe. WM B. PLUMMER

A simple and efficient hydrogen electrode. C. P. SIDERIS. *Science* **62**, 331-2 (1925).—The cell consists of a flat-bottomed glass tube 7.5 cm. long and 2.5 cm. diam., fitted with a 3-holed rubber stopper. The H conducting tube is 15 cm. long and 0.5 cm. diam., the lower end being bent 180° and terminating in a pointed tip the opening of which should be between 0.5 and 0.75 mm. diam. and be placed exactly under the center of the conical spiral electrode described below. The upper end of the H conducting tube is attached to a H generator by means of a rubber tube. The Pt electrode is made by winding 15 to 25 cm. of 22 gage, or larger wire, around a conical object with the windings 1 to 1.5 mm. apart, forming, when in place, the outline of an inverted funnel. One free end of the wire is fused into a glass tube 10 cm. long and 0.5 cm. diam., where the wire comes in contact with Hg. This tube and the H conducting tube fit the rubber stopper tightly. The 3rd hole of the rubber stopper holds the salt bridge or tube contg. either concd. KCl soln. or agar-KCl. This tube fits the rubber stopper loosely to allow the escape of H. With this app. detns. of H-ion concn. may be made with 5 to 10 cc. of liquid. The entering H gas keeps the liquid agitated without the use of a mech. stirrer. This form of app. gives a larger surface area of Pt than other types. L. W. RIGGS

Hot-wire anemometer for measuring air flow through engine radiators. C. G. F. ZOBEL AND L. B. CARROLL. *Chem. News* **131**, 260(1925). E. J. C.

Silica to glass and to metal joints. L. J. BUTTOLPH. *J. Optical Soc. Am.* **11**, 519-57(1925). E. H.

Phosphor-bronze helical springs from the standpoint of precision instruments. W. G. BROMBACHER. *J. Optical Soc. Am.* **11**, 519-47(1925). E. H.

Glass pump plungers lessen replacements. D. S. CHAMBERLIN. *Chem. Met. Eng.* 32, 818-9(1925).—Glass offers certain advantages over porcelain for pump plungers. It is resistant, very smooth, and very hard, costs less, can be blown in an iron-split mold to exact dimensions, and the coeff. of expansion is very close to that of steel and neat cement. Development by pump manuf. is needed. W. H. BOYNTON

- Filter for milk or other liquids.** D. C. KERCKHOFF AND R. COPP. U. S. 1,563,904, Dec. 1.
- Inclined steam chest evaporator for milk or other liquids.** H. D. MILES. U. S. 1,562,713, Nov. 24.
- Apparatus for distilling methanol from wood, and for like purposes.** A. F. FRAME. U. S. 1,562,880, Nov. 24. The app. comprises a special arrangement of feed pipes and a rotary cylinder, with rotatable feed screws in the pipes and cylinder.
- Rotary apparatus for dry distillation of ligneous acetate material, etc.** N. STRATHAM. U. S. 1,566,778, Dec. 22.
- Apparatus for steeping grains, extracting sugar from beets and for other purposes.** P. A. SINGER. U. S. 1,564,980, Dec. 8. The app. comprises a treating chamber in which a partial vacuum may be maintained for steeping grain, extg. sugar, washing black ash in the soda industry, extg. oils from seeds and for various other processes.
- Apparatus for aerating or carbonating beverages or other liquids.** P. A. GARRETT. U. S. 1,562,628, Nov. 24.
- Apparatus and air circulation methods for drying and solvent recovery.** G. D. HARRIS. U. S. 1,564,782-3, Dec. 8.
- Feeding solids or semisolids to chemical apparatus.** G. A. BERRY. U. S. 1,563,066, Nov. 24. In app. such as that used for reducing PhNO_2 to PhNH_2 , vapor from a treating receptacle is condensed and refluxed to the receptacle and the refluxing condensate is utilized to carry Fe filings or other solid or semisolid substances into the receptacle.
- Feeding solids and semisolids to chemical apparatus.** G. A. BERRY. U. S. 1,565,249, Dec. 15. An app. is arranged for utilizing the condensate flowing back to a reaction vessel for carrying solid or semisolid reagents into the vessel. (See U. S. 1,563,066; above.) The app. may be used for feeding Fe filings to a reaction vessel in reducing PhNO_2 to form PhNH_2 .
- Closed jacketed kettle for digestion, extraction and filtration.** L. C. DANIELS. U. S. 1,562,870, Nov. 24. The app. is adapted for purifying crude benzanthrone with chlorobenzene as a solvent, etc.
- Apparatus for evaporating liquids by indirect heating.** K. I. E. THUNHOLM. U. S. 1,562,525, Nov. 24. The app. comprises superposed plates with annular channels for the heating medium.
- Apparatus for removing air from water or for removing other gases from liquids.** H. FOTHERGILL. U. S. 1,562,827, Nov. 24. A falling spray of the liquid is passed over heating surfaces.
- Apparatus for liquefaction and rectification of air or other gas mixtures.** C. E. RECORDON AND J. W. HILLE. U. S. 1,562,915, Nov. 24.
- Apparatus for impelling gases by heating.** C. G. SMITH. U. S. 1,546,287-8, Dec. 8.
- Apparatus for pressing paraffin, etc.** A. VITENKO. U. S. 1,560,443, Nov. 3.
- Device for automatic liquid-level control in evaporators or other apparatus.** H. P. MILKER. U. S. 1,563,097, Nov. 24.
- Penetrometer.** F. RODLER. U. S. 1,565,502, Dec. 15.
- Test blocks for determining temperatures in heat-treating furnaces, etc.** O. PEDERSEN. U. S. 1,563,104, Nov. 24.

Regenerative furnace adapted for heating metals or melting glass. N. I. IVANOVSKY. U. S. 1,565,370, Dec. 15.

Monolithic magnesite tubing for furnace tap-holes. H. G. FRIEDRICH. U. S. 1,565,084, Dec. 8.

Heat governor for gas-fired industrial ovens. H. W. PARTLOW. U. S. 1,532,340, April 7, 1925. A thermostatic device is adapted for use on annealing, tempering, enameling or core-baking ovens, etc.

Device for testing the compression strength of foundry sand, loam, or other materials in granular form. L. TREUHEIT. U. S. 1,559,921, Nov. 3.

Viscometer. P. J. THOMAS. U. S. 1,565,119, Dec. 8.

Hydrometer freezing-point tester for automobile radiator solutions, etc. W. F. ALBRECHT and J. SHEBOL. U. S. 1,550,412, Aug. 18.

Thermostatic gas governor. H. W. PARTLOW. U. S. 1,551,212, Aug. 25.

Thermostatic device for controlling flow of liquids through pipes. H. T. WOOLSON. U. S. 1,564,504, Dec. 8.

Thermostat for controlling water heaters, etc. E. A. SCHOLTZ. U. S. 1,566,699, Dec. 22.

Bomb calorimeter. G. E. SCHOLES. U. S. 1,563,662, Dec. 1.

X-ray apparatus. W. MEYER. U. S. 1,562,650, Nov. 24.

X-ray apparatus. H. P. PILON. U. S. 1,567,012, Dec. 22.

X-ray apparatus. C. N. MOORE. U. S. 1,567,024, Dec. 22.

Controlling gas pressure in X-ray tubes or similar devices. R. W. KING. U. S. 1,566,279, Dec. 22. A portion of the gas is ionized at a rate which is proportional to the pressure, and gas is supplied to the device at a rate controlled by the ionization.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND BRIAN MEAD

Services of the American Chemical Society to the nation. J. F. NORRIS. *Nucleus* 3, No. 2, 5-7(1925). E. J. C.

The organization of scientific research throughout the [British] Empire. T. H. HOLLAND. *J. Roy. Soc. Arts* 74, 3-27(1925). E. J. C.

Hindu chemistry. C. A. SILBERRAD. *Chemistry & Industry* 44, 1179-80(1925). E. H.

Ernst Erdmann. VORLANDER. *Z. angew. Chem.* 38, 980-1(1925). ANON. *Chem.-Ztg.* 49, 861(1925).—Obituaries. E. J. C.

The work of Celso Ulpiani in chemistry and in agriculture. The *Georgics* of Virgil and the political and agricultural ideals of Ulpiani. F. SCURTI. *Ann. chim. applicata* 15, 331-46(1925).—A detailed review of the work of Ulpiani, his contributions to org. chemistry and to the chemistry of agriculture and fermentation, and his development of the ideas set forth in the agricultural writings (*Georgics*) of Virgil. C. C. D.

Electronation. H. P. CADY AND ROBERT TAFT. *Science* 62, 403-4(1925).—The authors point out the objections to the use of the terms "reduction" and "oxidation" in the broad sense and propose instead, resp., *electronation* (the addn of an electron or electrons to an element) and *de-electronation*. A. M. PATTERSON

The allotropy of manganese. A. J. BRADLEY. *Phil. Mag.* 50, 1018-30(1925).—Three allotropes of Mn have been discovered. Two are normally present in commercial Mn and have been isolated and photographed by the X-ray method. They are called β and γ Mn. The β Mn is stable from 150° to 850° and γ Mn from 650° up. From 650° to 850° both forms are stable, and for each temp. there is a given equil. mixt. The third allotrope of Mn which has so far been obtained electrolytically only is apparently stable only at low temps. It is intermediate between a body-centered and a face-centered cube. By heat treatment α Mn (electrolytic variety) is converted into the β and γ forms but the process does not seem to be reversible. See also WESTGREN and PHRAGMEN (*C. A.* 19, 2910). S. C. L.

The crystal structures of the sulfides of mercury. H. E. BUCKLEY AND W. S. VERNON. *Mineralog. Mag.* 20, 382-92(1925).—The structures of the 2 modifications of HgS, cinnabar and metacinnabarite, were detd. The materials used were finely powdered massive cinnabar, and in the case of the cubic modification, a chem. pptd. sulfide, washed and dried. *Cubic mercuric sulfide*.—The structure is of the zinc-blende type, with 4 mols. of HgS to the unit cube; $a_0 = 5.854$ A. U. The distance between adjacent Hg and S atom centers = 2.54 A. U. *Cinnabar*.—The spacings correspond

with a hexagonal space-lattice with 3 mols. to the unit cell; $a_0 = 4.160$ A. U., $c_0 = 9.540$ A. U. The Hg atoms are arranged on a simple rhombohedral lattice, while S atoms are dispersed in the (0001) planes forming spirals running parallel to the vertical axis. The distance apart of the S atoms in the same spiral = 3.52 A. U.

W. F. HUNT

The crystal structures of sodium and potassium azides and potassium cyanate and the nature of the azide group. S. B. HENDRICKS AND L. PAULING. *J. Am. Chem. Soc.* **47**, 2904-20(1925).—The crystal structures of NaN_3 , KN_3 , and KCNO have been detd. The rhombohedral unit of structure of NaN_3 has $\alpha = 38^\circ 43'$ and $a = 5.481$ A. U., and contains 1 NaN_3 . The Na atom is at 000, the N atoms at $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, with u equal to 0.423. The tetragonal unit of KN_3 has $a = 6.094$ A. U. and $c = 7.056$ A. U., and contains 4 KN_3 . The K atoms are at $00\frac{1}{2}$, $00\frac{1}{2}$, $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, and the N atoms at $0\frac{1}{2}0$, $\frac{1}{2}00$, $\frac{1}{2}0\frac{1}{2}$, $0\frac{1}{2}\frac{1}{2}$; $u(\frac{1}{2} + u)0$, $(\frac{1}{2} - u)u0$, $\bar{u}(\frac{1}{2} - u)0$, $(\frac{1}{2} + u)u0$, $(\frac{1}{2} + u)\frac{1}{2}$, $u(\frac{1}{2} - u)\frac{1}{2}$, $(\frac{1}{2} - u)\bar{u}\frac{1}{2}$, $\bar{u}(\frac{1}{2} + u)\frac{1}{2}$, with u equal to 0.135. The structure of KCNO is shown to be closely similar to that of the azide; the unit of structure has $a = 6.070$ A. U., and $c = 7.030$ A. U. Neither K nor Na azides shows mol. segregation; the azide ion is, however, easily distinguished. This ion is shown to possess not a ring structure, but a linear arrangement of the three N atoms. Possible electronic configurations are discussed in light of these results. A consideration of the previously studied structures of sodium and potassium acid fluorides is shown to indicate that the acid fluoride ion is similar in structure to the azide ion and the cyanate ion.

GEORGE I. CLARK

The crystal structure of carbon dioxide. J. C. McLENNAN AND J. O. WILHELM. *Trans. Roy. Soc. Can., Sec. III* (3) **19**, 51-6(1925); cf. *C. A.* **19**, 1816, 2149.—The crystal structure of CO_2 was investigated by the use of X-rays. A modified Debye and Scherrer camera with a Shearer X-ray tube provided with a Cu anti-cathode was used. The low temp. was produced by using liquid air. A const. very low pressure was provided in the tube in order to obtain strong Cu X-rays. Plates showing the diffraction pattern are reproduced. The crystal form for CO_2 was found to be in the tetragonal system with an axial ratio of one, showing the structure to be cubic. The diffraction pattern did not show all the lines of a simple cube so the authors present a crystal structure exhibiting cubic symmetry of a special kind, the side of the unit cube being 5.76 A. U., the distance between the C and the O atoms 1.25 A. U., and the moment of inertia 8.2×10^{-39} g. sq. cm.

J. W. SHIPLEY

The crystal structure of lead dioxide examined with X-rays. A. FERRARI. *Atti accad. Lincei* [6], **2**, 186-91(1925).—Recently F. (C. A. **19**, 2890) found that MgF_2 has a tetragonal structure of the "rutile" type. Crystallographically PbO_2 resembles rutile and cassiterite and so the Debye photograph of pure PbO_2 was prepd. PbO was found in this way also to have the tetragonal structure of the "rutile" type. The elementary cell contains 2 mols. PbO_2 ; $a = 4.98$ A. U., $c = 3.40$ A. U. The axial ratio $c/a = 0.682$ is somewhat different from that detd. crystallographically. The d detd. from the dimensions of the cell is 9.42, which agrees well with direct detns. All prepns. obtained in various ways showed this same tetragonal form. The supposed hexagonal modification of Geuther and Lüdecke does not exist.

E. J. WITZEMANN

X-ray analysis of mixed crystals of silver halides. R. B. WILSEY. *J. Frank. Inst.* **200**, 739-46(1925).—Precision X-ray powder spectra are taken with the following results: AgCl , simple cubic, $a_0 = 2.770$; $\text{AgCl} + \text{AgBr}$, miscible in all proportions, simple cubic with a_0 following the linear law; AgBr , simple cubic, $a_0 = 2.884$; AgI , diamond cubic and hexagonal; $\text{AgI} + \text{AgBr}$, mixts. up to 70 mol. % AgI simple cubic with increasing a_0 to max. of 3.007 A. U., beyond which diamond cubic or hexagonal lattice predominates; CaWO_4 tetragonal. The enlargement of the AgBr lattice by incorporation of AgI may be connected with the increased speed obtainable in photographic emulsions of AgBr containing small amts. of AgI .

GEORGE I. CLARK

The preparation and crystal structure of ferrous oxide. R. W. G. WYCKOFF AND E. D. CRITTENDEN. *J. Am. Chem. Soc.* **47**, 2876-82(1925).—Pure FeO from Fe_2O_3 melted with Fe gives an X-ray pattern showing a "NaCl" structure, edge of unit cube = 4.29 A. U.; calcd. d. = 5.99.

G. CALINGBART

The structure of high- (or β)-quartz. R. W. G. WYCKOFF. *Science* **62**, 496-7(1925).—The hexagonal unit cell of α -quartz (temps. below 575°) has the dimensions $a_0 = 4.903$, $c_0 = 5.393$ A. U., and contains 3 mols. of SiO_2 . The only simple unit cell for β -quartz which can account for data now obtained from powder and 6 Laue photographs is a similar one with $a_0 = 5.01$, $c_0 = 5.47$ A. U., and contains 3 mols. as calcd. from the $d_{hkl} = 2.518$. The structure is that of the 2 enantiomorphic arrangements.

6D-4 (c) and (j) and 6D-5 (c) and (j) with Si atoms (c) at $\frac{1}{2}\frac{1}{2}\frac{1}{2}$, $0\frac{1}{2}0$, $\frac{1}{2}0\frac{1}{2}$, and O atoms (j) at $u\frac{1}{2}\frac{1}{2}$, $2\bar{u}\frac{1}{2}\frac{1}{2}$, $u\ 2u\frac{1}{2}$, $\bar{u}u\frac{1}{2}$, $2uu\ \frac{1}{2}$, $\bar{u}\ 2\bar{u}\frac{1}{2}$, where $u = 0.20$. GEORGE L. CLARK

The structure of alpha and beta quartz. W. BRAGG AND R. E. GIBBS. *Proc. Roy. Soc. (London)* **109A**, 405-27 (1925).—A partial structure of quartz (parameters of Si) was previously established (C. A. **8**, 1699). From the fact that trigonal α -quartz and hexagonal β -quartz must have a very similar structure, the missing parameters for the statement of the O atoms in the lattice are calcd. The arrangement of the O atoms round the Si atoms so found is very close to tetrahedral. Values of the changes in the position of the atoms when α -quartz is transformed into β -quartz will be given later. G. CALINGAERT

The isomorphism between quadrivalent uranium and zirconium. LORENZO FERNANDES. *Atti accad. Lincei* [6], **2**, 182-6 (1925).—Until recently little work on the isomorphism of the various quadrivalent rare earth elements had been done. By the X-ray methods Goldschmidt and Thomassen (C. A. **17**, 1609) found that CeO_2 , ThO_2 and UO_2 are isomorphous. Cuttica and Tocchi (C. A. **19**, 425) prepd. double nitrates of NH_4 and Ni with Ce^{IV} and Th. The case of Zr has not been examd. yet. Recently F. found by the X-ray method that ZrO_2 exists in only 1 form and that the variations observed in its d. are due to the inclusion of gases. In a previous paper F. (C. A. **19**, 2892) studied the isomorphism of $\text{Zr}(\text{SO}_4)_2$ and $\text{Ce}(\text{SO}_4)_2$ and found that they are completely miscible in the solid state. In this paper the compds. $\text{Zr}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ and $\text{U}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ which cryst. in the rhombic system like the corresponding Ce and Th salts were studied. These 4 salts of Zr, U, Ce and Th constitute an interesting isomorphous series capable of giving solid solns. in a relatively vast range and this isomorphism serves to explain the frequently relatively high U content of Zr minerals. Probably hafnium sulfate is also isomorphous with the 4 above compds. E. J. W.

Some theoretical calculations of the physical properties of certain crystals. J. E. LENNARD-JONES (formerly J. E. Jones) AND P. A. TAYLOR. *Proc. Roy. Soc. (London)* **109A**, 476-508 (1925); cf. C. A. **19**, 756, 1093, 1973.—Methods are given of obtaining the forces between certain Ne-like and Ar-like ions. They are used with success to account for the observed distances in certain NaCl-type crystals. They can also be used to make predictions of crystal consts. not yet measured. The values of compressibility, elasticity and other consts. of the same crystals are also calcd. and compared, when possible, with expt. The repulsive force of Ne-like ions in crystals can well be represented by an inverse 11th-power law and that of Ar-like ions by an inverse 9th-power law. In the latter case the inverse 15th power is a better approximation for large distances. G. CALINGAERT

Cristobalite. LOUIS LONGCHAMON. *Compt. rend.* **181**, 614-6 (1925).—Observations on the crystn. of tridymite from solns. in which cristobalite is dissolving, and the orientation of these tridymite crystals on the cristobalite residue. G. L. C.

Pseudo-symmetry of racemic potassium chlorosulfacetate. F. M. JAEGER. *Proc. Acad. Sci. Amsterdam* **28**, 423-5 (1925).—See C. A. **19**, 3044. E. J. C.

The chemistry of solids. C. H. DESCH. *Chemistry & Industry* **44**, 903-13, 924-9 (1925); *Bull. Brit. Non-Ferrous Metals Res. Assoc.* **1925**, No. 16, 10-5.—An interesting abridg., reviewing the various problems dealing with reactions in the solid state. H. S. v. K.

Flames of atomic hydrogen. IRVING LANGMUIR. *Science* **62**, 463-4.—Twenty-amp. arcs from a const. current transformer were passed between 2 W rods 6 mm. in diam. mounted transversely in an aluminum tube through which a stream of H flowed and burned at the open end. The at. H could be blown out of the arc and formed an intensely hot flame burning to mol. H_2 and liberating 90,000 cal. per g. mol. Mo, W and quartz could be melted, as also Fe without contamination by C, O, or N and, without fluxes, alloys contg. Cr, Al, Sr, or Mn could be welded without surface oxidation. GEORGE L. CLARK

New investigations on the melting and vaporization of carbon. H. ALTERTHUM. *Z. tech. Physik* **6**, 540-4 (1925).—A review of the methods used and the results obtained by past investigators. J. H. P.

The ignition of carbon disulfide vapor and its phosphorescent flame. HAROLD B. DIXON. *Fuel in Science & Practice* **4**, 401-10 (1925).—A version in English of a previous article (cf. C. A. **19**, 2893). C. C. DAVIS

Supersaturation of gases in liquids. N. D. CLARE. *Trans. Roy. Soc. Can., Sec. III* **3**, 19, 32-3 (1925); cf. Metschl, C. A. **18**, 2451.—Supersatd. solns. of O_2 up to about 250 atm. pressure on release of pressure sometimes formed clouds of bubbles in the liquid away from the walls. A metal hydraulic gage and a glass capillary of 0.3 mm. bore provided with a magnetic stirrer were used. J. W. SHIPLEY

The initiation of bubbles in supersaturated solutions of gases. F. J. FARNCOMB. *Trans. Roy. Soc., Can., Sec. III* (3) **19**, 32(1925); cf. *Trans. Roy. Soc.* **16**, 271(1922).—PbCl₂ crystals, phenol globules, freshly pptd. AgI, colloidal As₂S₃ and Fe(OH)₃, starch and Pt wire had no appreciable effect on the initiation of bubbles. Crystals of C₆H₅-COOH, salicylic acid and phthalide, Fe wire and paraffin wax globules had a small but decided effect. Pptd. AgI, CaSO₄ and boric acid crystals had a very strong effect. Many of the solids used were formed within the soln., thus eliminating preformed gas films. Bubbles are initiated chiefly by substances wetted with difficulty by the solvent.

J. W. SHIPLEY

Density and temperature. V. W. HERZ. *Z. Elektrochem.* **31**, 512-4(1925); cf. *G. A.* **18**, 3501.—For a large no. of tabulated substances the abs. temps. at which the quotient of the ds of the liquid (*D*) and of the satd. vapor (*S*) is a given chosen value, are approx the same fraction of the crit. temps. For any one substance the successive differences between the logarithms of the ratios *D/S* decrease as the temp. is lowered from the crit. value by equal intervals, pass through a min. and again increase.

GEORGE L. CLARK

Measurement of the vapor tension of gasoline and other volatile liquids. HAROLD S. DAVIS. *Ind. Eng. Chem.* **17**, 1136-8(1925).—An app. is described for detn. of vapor tension by detn. of the additional pressure required to compress a mixt. of air satd. with the given vapor, and in contact with a large excess of the liquid, to 0.5 of its original vol. Detns. made on standard liquids show remarkable accuracy. Errors inherent in the use of the U. S. Bur. of Explosives vapor pressure bomb method are discussed.

WM B. PLUMMER

Some phenomena in capillary chemistry. RENÉ DUBRISAY. *Bull. soc. chim.* **37**, 996-1008(1925).—See *C. A.* **18**, 490, 1074, 3131.

JAMES M. BELL

The adsorption of some vapors by alumina gel. J. H. PERRY. *J. Phys. Chem.* **29**, 1462-8(1925).—By a dynamic method, the adsorption of 10 vapors by alumina gel has been measured at 25°. The satn. values (g. vapor per 10 g. of gel) are: CS₂ 2.96; CCl₄ 3.6; CHCl₃ 3.8; C₂H₄Cl₂ 3.7; C₂H₅COOH 2.7; CH₃C₂H₅CO 2.46; hexane 2.47; CH₃Ac 2.56; CH₂Cl₂ 3.4; C₆H₅CH₃ 2.8

J. H. PERRY

A deviation from Poiseuille's law. B. MARZETTI. *Atti accad. Lincei* [6], **2**, 169-73 (1925).—M. found that nonvulcanized rubber made to flow slowly through a tube or a small hole shows a velocity of outflow that is not a linear function of the pressure as required by Poiseuille's law. The app. data and some discussion of this case are given.

E. J. WITZEMANN

Electro-ultrafiltration. II. BRECHOLD. *Z. Elektrochem.* **31**, 496-8(1925).—A balloon-shaped ultra-filter dips into the soln. compartment of an ordinary ultra-filter and electrodes are placed on the filtrate side of both. A potential gradient of 40 v./cm. is used and the process is completed in 1/175 of the time necessary for dialysis and 1/13 of the time necessary for ultra-filtration.

D. S. VILLARS

Colloid systems in nitrobenzene. F. S. BROWN AND C. R. BURY. *J. Phys. Chem.* **29**, 1312-6(1925).—When solns. of alcohols, phenols, or org. acids in dry C₆H₅NO₂ are agitated with dehydrating agents such as P₂O₅, CaCl₂, ZnCl₂, or SiO₂, colloidal solns. of the latter result, which pass through filters, show the Tyndall effect and exhibit brilliant Christianson colors. With CaCl₂ and P₂O₅ sols contg. several g. per 100 g. C₆H₅NO₂ may be obtained which set to gels on standing. Traces of H₂O cause rapid coagulation. AcOH and PrOH are adsorbed from C₆H₅NO₂ in accordance with Freundlich's adsorption isotherm. The amt. of CaCl₂ peptized varies with the concn. of peptizing agent in accordance with a similar equation.

F. L. BROWNE

Emulsion films. H. N. HOLMES. *J. Phys. Chem.* **29**, 1205-10(1925).—The theories of the stability of emulsions are briefly reviewed. Polar substances in true soln. sometimes act as emulsifying agents. Emulsions of C₆H₆ in H₂O are stabilized by MeOH, EtOH, allyl alc., phenol, resorcinol, fatty acids above caprylic, sulfonic acids, benzonitrile, rancid fats and neutral fats (less effectively). Higher alcs., glycol, glycerol, benzyl alc., sugars, aldehydes, ketones, nitro and amino compds. are not effective emulsifying agents. Emulsifying agents are believed to form oriented, monomol films at the interface. This seems to be the only explanation for the emulsification of Nujol in H₂O by EtOH. Gum dammar emulsifies H₂O in C₆H₆, yet it is in true soln. and does not lower the surface tension of C₆H₆. The use of gum dammar to emulsify H₂O in oils has com. possibilities for *printers' inks, medicated salves and ointments* and in *color photography*. The viscosity of emulsions is affected by the nature of the emulsion film as well as by the vol. concn. of the 2 phases.

F. L. BROWNE

Hydrophobe and hydrophile colloids. JACQUES LOEB. *J. chim. phys.* **21**, 169-87 (1924); cf. *C. A.* **18**, 928.—The principle of membrane equil. explains the sp. properties

of the two types of sols: hydrophilic, such as the proteins, and hydrophobic, such as mastic, graphite, collodion. The Donnan equil. depends in all cases on the charges of the colloidal particles, which arise in part from ionization and in part from an elec. double layer. The origin of the charge is the only point of difference between the 2 types of colloids. In the hydrophilic sols the charge is due to ionization and in the hydrophobic to the double layer that is set up between the particle and the water. A double layer exists also at the periphery of solid particles of electrolytes such as proteins and $\text{Fe}(\text{OH})_3$; in such cases ionization of the particles affects only the difference of potential of the double layer.

HARRY B. WEISER

Protein films on collodion membranes. D. I. HITCHCOCK. *J. Gen. Physiol.* **8**, 61-74(1925).—Highly permeable collodion membranes adsorb weighable amts. of gelatin and egg albumin from soln. at 37° . Langmuir's equation (*J. Am. Chem. Soc.* **40**, 1368, 1384; cf. *C. A.* **12**, 2152) expresses fairly well the effect of concn. on adsorption while Freundlich's equation (*Kapillarchemie* 3rd. ed. p. 151, 232(1923)) does not fit the exptl. results. Max. adsorption occurs in solns. of isoelec. protein. The effects of acids and salts on the amt. of gelatin adsorbed resemble their effects on viscosity (cf. Loeb, *Proteins and the Theory of Colloidal Behavior*, 2nd. ed. 1924), but are opposite in direction. The effects of pH on the amt. of adsorbed gelatin and fluidity of gelatin solns. are nearly parallel. Membranes made impermeable by long drying adsorb little gelatin from soln. In membranes of varying permeability, the max. amt. of gelatin adsorbed increases with the permeability and thickness of the membranes. Within limits the permeability seems to be a linear function of the relative pore surface of the membrane. The gelatin film decreases the permeability of the membranes to water. Since the relative cross-section of the pore openings is a linear function of the amt. of adherent gelatin, it is concluded that gelatin forms a film inside the pores.

CHAS. H. RICHARDSON

Contribution to the theory of permeability of membranes for electrolytes. L. MICHAELIS. *J. Gen. Physiol.* **8**, 33-59(1925).—Expts. with apple skin, parchment paper and dry collodion membranes show that they are less permeable for anions than for cations. Anions permeate parchment-paper membranes relatively much less than cations, whereas apple skin and dry collodion membranes are nearly impermeable to them. In membranes which are permeable for cations but not for anions, the permeability for these ions follows the same order as their mobilities in free aq. soln. But the differences are greatly magnified and whereas the mobility ratio of H^+ and Li^+ in aq. soln. is 1:10, in the collodion membrane it is 1:900. The cause of this retardation of ion mobility within the membrane is probably the friction of the water envelope dragged along by the ion in the capillary canals of the membrane. The difference in mobility between cations and anions is probably due to the elec. charge on the walls of the canals. These theoretical considerations are developed mathematically and the deductions are tested by expt.

CHAS. H. RICHARDSON

Soaps and the theory of colloids. J. W. MCBAIN. *Nature* **115**, 805-7(1925); cf. *C. A.* **19**, 3399.—A lecture. F. N. S.

A rational notion for the expression of the actual reaction of solutions. D. GIRIBALDO. *Bull. soc. chim. biol.* **7**, 652-64(1925).—See *C. A.* **19**, 1218. A. T. C.

Electrical dispersion of liquids. Phenomena accompanying the passage of an electric current through contiguous immiscible electrolytes. VICTOR COFMAN. *J. Phys. Chem.* **29**, 1289-302(1925).—Elec. current under a voltage varying from 0 to 220 was passed through a system of 2 conducting, immiscible liquids, such as a soln. of KI_x in $\text{C}_6\text{H}_5\text{NO}_2$ and a soln. of KI in H_2O . Phenomena of liquid dispersion, chem. reactions, endosmosis, and polarization occurring at the interface are described in detail. They show that the transfer of electricity from one electrolytic phase to another does not take place in every case by means of ions only, but that it is also effected by electrons and by larger complexes of ions and solvent. When ion A^+ in phase I and ion D^- in phase II meet at the interface one of three things may happen. (a) if compd. AD is insol. in both I and II, a ppt. forms as a membrane and gives rise to electro-endosmosis, polarization, and stenolysis, (b) if AD is sol. in both phases, the current is carried across the interface by the ions, the fraction of the current carried by each ion depending upon the soly. and the diffusion consts. of AD and the mobilities of the ions in I and II; (c) if AD is sol. in II but not in I, A^+ ions pass from I to II but no D^- ions cross in the opposite direction, i. e., the interface behaves as a semi-permeable membrane. Negatively charged droplets of II enter I as a very fine dispersion. These droplets move very rapidly at first, but then seem to lose their charge, slow up, become positively charged and move back toward the interface again. The charged droplets trying to move across the interface under the elec. potential are opposed by the interfacial tension.

This accounts for the observed fact that a certain min. voltage must be attained before dispersion takes place.

F. L. BROWNE

Solubility relations in isomeric organic compounds. V. The construction of the ideal ternary solubility diagram and its use in analysis. G. T. KOHMAN and D. H. ANDREWS. *J. Phys. Chem.* **29**, 1317-24(1925); cf. *C. A.* **18**, 3518.—Three simple graphical methods are described for constructing and interpreting soly. diagrams of ternary systems which yield ideal, or nearly ideal solns. Mixts. of *o*, *m* and *p* isomers afford examples of such systems. The first method employs a solid model, the second a projection of the solid model on a plane surface, and the third a plot of $\log N$ vs. $1/T$ (where N is the mol. fraction of the solute in the soln. in equil. with cryst. solute at temp. T). This is a straight line for the case of ideal soln. The same methods, with slight modifications, can be used where the solns. depart somewhat from ideality. The soly. diagram can be detd. from a small no. of observations, for instance from detns. of the primary f. p. of a known mixt. of 2 components, their eutectic temp., the m. p. of each, and the eutectic temp. of the 3rd component with either of the others. By means of the diagram, a mixt. of the components can be analyzed with an accuracy of the order of 1 or 2% by observation of the primary f. p. and the influence on the f. p. of small addns. of each of 2 of the components. The method can be used even when small amts. of an impurity such as H_2O are present.

F. L. BROWNE

Electrical conductivity in benzene solutions. SOPHIE JAKUBSOHN. *Z. physik. Chem.* **118**, 31-6(1925).—The sp. cond. of $AlBr_3 \cdot H_2S$ at 25° in C_6H_6 ($\kappa < 1 \times 10^{-13}$) is found to vary from 0 for solns. under 20% to 3.54×10^{-4} for a 53.99% soln. (which is a satd. soln.). The mol. cond. and mol. wt. (as detd. from cryoscopic measurements) increase with increasing concn. Association or solvation thus seems to favor the dissociation process. When electrolyzed, H_2 is evolved at the cathode and Br_2 at the anode (where secondary bromination compds. are formed). The decompn. p. d. of a 45% soln. is 0.74 v. at 25° .

D. S. VILLARS

Conductivity and electrolysis of iodine trichloride in acetic acid. B. P. BRUNS. *Z. physik. Chem.* **118**, 89-98(1925).—Pure ICl_3 dissolves in water-free $AcOH$ to form clear 33% solns. If there are traces of water present, the ICl_3 hydrolyzes and HIO_3 ppts. for concns. over 10%. The $AcOH$ used had a sp. cond. of 0.8×10^{-9} reciprocal ohms. The mol. cond. decreases from a value of about 0.5 (at 18°) at a diln. of 2 l. to a min. (0.1) at a diln. of 10 l. and then increases so as to reach the original value of 0.5 at a diln. of 1000 l. For concns. of 6.45 and 7.27% there is a break in the temp.-cond. curve at a temp. between 20° and 30° and for a concn. of 10.50% there is a min. at about 30° . On electrolyzing, an amt. of Cl is pptd. at the anode twice that required by Faraday's law and it is found that the whole ICl_3 mol. goes to the anode. (Cf. Brunner, *Z. physik. Chem.* **84**, 385.) There is little if any decompn. p. d. It is inferred that a complex, $ICl_3 \cdot nAcOH$, is formed which dissociates into the mols. when the temp. is raised above 30° (this accounts for the break in the temp.-cond. curve) and also into the ions ICl_2^{--} and $(AcOH)_n^{++}$ (this accounts for the electrolytic phenomena).

D. S. VILLARS

Ion antagonism. R. MINAKAMI. *Biochem. Z.* **158**, 306-18(1925).—The effect of the addn. of various salts and mixts. of salts of univalent and bivalent metals (Na, K, Li, Ca, Mg, Ba, etc.) on the surface tension of 0.1 and 0.2% soap solns., Na oleate, was measured. The curves of surface tension changes show the antagonism between univalent and bivalent ions such as Ca and Na or Li and Mg.

F. A. CAJORI

Cryoscopic measurements for verification of Debye-Hückel's theory on solutions of electrolytes in organic solvents. E. SCHREINER and O. E. FRIVOLD. *Naturwissenschaften* **13**, 859(1925).—Measurements are given of $1-\gamma$ (γ is osmotic coeff.) of $LiCl$ solns. in cyclohexanol (f. p. lowering 38.22° for 1 molal per l.; m. p. 23.6° ; $d_{20.6} = 0.9489$, dielec. const. at 25° 15.0). With an empirical value for the ion radius $a = 2.80 \times 10^{-8}$ cm. complete agreement is obtained between exptl. data and theory (concns. examined ranged from 0.00037 to 0.0142 molar).

B. J. C. VAN DER HOEVEN

Electrolytic solutions of low dielectric constant. PHILIP GROSS and OTTO HALPERN. *Physik. Z.* **26**, 636-42(1925).—The Debye-Hückel theory of electrolytic solns. yields a value of the osmotic coeff. $f_0 = 1 - (\epsilon^2 \kappa / 6DkT) \cdot (\sum \nu_i z_i^2 \sigma_i / \sum \nu_i)$ (Debye-Hückel notation, cf. *C. A.* **17**, 2665; **18**, 190). If the dielec. const. D is small, ionized solutes may exhibit very small values of f_0 . The exptl. detns. of f. p. lowering, etc., on such solns. in many cases yield results pointing towards considerable association of the solute mols., although cond. detns. show that some ions must be present. The $A-\gamma$ curves in general are abnormal, and cannot be interpreted on the classical theory of electrolytes. In the D.-H. theory of strong electrolytes, complete dissocn. into ions is assumed and the variation of the osmotic and activity coeffs. with concn. is explained

on the basis of change of the elec. potential between the charges on the ions. Thermodynamic considerations yield certain stability conditions which indicate the presence of both ions and undissociated mols. of the solute in solns. of low D , in view of the abnormally low osmotic effects yielded by these solns. Significant for this point of view is that solns. that do not conduct current show no abnormal osmotic effects. No numerical evidence is quoted; in order to apply D.-H. equations it is necessary to know the effect of solute concn. on the dielec. const. of the soln. A review of previous hypotheses used to explain the behavior of solns. of low D , and a bibliography are given.

F. C. KRACEK

The calculation of the equivalent conductivity of strong electrolytes at infinite dilution. I. Aqueous solutions. A. FERGUSON AND I. VOGEL. *Phil. Mag.* **50**, 971-85 (1925).—F. and V. recommend the Storch equation (*Z. physik. Chem.* **19**, 13 (1896)) for the formulation of the diln. law of electrolytes. They develop a more rigid method of evaluating the consts. involved in it and then apply it to existing cond. data. Comparison is made by applying other formulas to the same data. S. C. L.

Hydrogen peroxide as an oxidizing agent in acid solution. III. W. H. HATCHER. AND G. W. HOLDEN. *Trans. Roy. Soc. Can.*, Sec. III (3) **19**, 11-9 (1925); cf. C. A. **19**, 924.—Glyoxylic acid was prepd. by the electrolytic reduction of oxalic acid, purified through sepn. as Ba glyoxylate and then reformation of the acid by addn. of H_2SO_4 . After concn. over H_2SO_4 in a vacuum desiccator the crystals forming were sepd., dried and recrystd. from water. Glyoxylic acid forms colorless, anhyd. monoclinic crystals, m. (without decompn.) 98° , sparingly sol. in alc., Et_2O , and C_6H_6 , but very sol. in H_2O . Aq. solns. are yellowish. It reduces ammoniacal $AgNO_3$ slowly. Its metallic salts are largely hydrated and quite stable even on boiling. Silver glyoxylate dissolves in H_2O at 18° to the extent of 0.007 g. per 100 cc. Ba glyoxylate with exactly 2 mols. of water was sol. to the extent of 0.005 g. per 100 cc. at 18° and 0.08 g. at 68° . Aq. solns. of the acid were analyzed by titration with KOH and phenolphthalein or by $KMnO_4$ in H_2SO_4 at room temp. The reaction with H_2O_2 was of the second order, yielding only water, carbonic and formic acids. Mineral acids and rise in temp. and concn. increase the already rapid reaction. The Na salt is especially reactive towards H_2O_2 .

J. W. SHIPLEY

Benzidine researches. I. Passivity of zinc dust. B. A. IZMAILSKII AND B. I. KOLPENSKII. *J. Chem. Ind.* (Russia) **1**, 31-2 (May-June, 1925).—In the manuf. of benzidine considerable trouble is sometimes experienced in reducing nitrobenzene by means of com. Zn dust and alkalis. The operation is very irregular, its duration and yield are very variable, and above all it is dangerous, since it may occasion an explosion, even if Zn dust is added gradually in small portions. Zn dust may acquire temporary reducing passivity under the influence of nitrobenzene, either by occluding H on the surface, or by forming the unstable combination ZnH_2 . The H_2 may suddenly be liberated in large quantities and cause an explosion. The phenomenon of temporary passivity of Zn dust can be avoided by preliminary treatment of the dust with NaOH soln. and either cooling overnight or heating to $60-70^\circ$ and quickly cooling, during this treatment of Zn excessive formation of gas must be carefully avoided. By means of the Zn paste thus prepd. 123 g. nitrobenzene (1 mol.) at an inside temp. of $92-96^\circ$ and bath temp. of 80° , is reduced to azoxybenzene with a yield of about 95% in the course of 90-105 min.; whereas by means of untreated Zn dust 6-12 hrs. is required to attain the same result. Some brands of Zn dust which had been rejected on account of being dangerous reacted very quietly after being subjected to the above preliminary treatment with alkalis.

BERNARD NELSON

Thermal decomposition of ozone. R. O. GRIFFITH AND ANDREW McKEOWN. *J. Chem. Soc.* **127**, 2086-96 (1925); cf. C. A. **18**, 789.—The velocity of deoxygenation was measured at 100° in glass tubes in the presence and in the absence of H_2SO_4 by the difference in pressure between the reaction tube and a compensator contg. air maintained at the same temp. The reaction is approx. bimol. For ozonized O_2 mixts. at pressures between 300 and 1000 mm. the bimol. coeff., k , (in liters/moles-minutes) is given by $k = 11,500/(360 + P)$ where P is the pressure in mm. of gas mixt. The addn. of one of the gases He , CO_2 , N_2 , A causes an increase in the velocity of deoxygenation (in the order named) if the reaction velocity is compared with that obtaining for the same partial pressure of O_2 in ozonized O_2 . This positive "catalytic" effect increases with increasing partial pressure of the added gas. A mechanism is suggested which involves the ideas of Christiansen (cf. C. A. **19**, 2157) and Boru and Franck (cf. C. A. **19**, 1655).

D. S. VILLARS

Photochemical and thermal decomposition of ozone. R. O. GRIFFITH AND A. McKEOWN. *Trans. Faraday Soc.* (advance proof) Oct. 1, 1925; cf. preceding ab-

stract.—A review of the work done on this subject with references. G. and McK. propose the mechanism: $O_3 \longrightarrow O_3^*$ (1); $O_3^* + O_3 \rightleftharpoons$ complex (2); complex $\longrightarrow 3O_2$ (3), where O_3^* represents an activated mol. The complex mol. formed by (2) is assumed to be capable of decomp. on collision with any other mol. present, the collision resulting in either the reverse reaction of (2) or in reaction (3). D. S. V.

The velocity of the reaction between hydrogen peroxide and the iodide ion. J. A. CHRISTIANSEN. *Z. physik. Chem.* 117, 433-47(1925).—The reaction velocity const. for the reaction $2H_2O_2 + I^- \longrightarrow 2H_2O + O_2 + I^-$ was detd. at 15° by measuring the rate of O evolution from 30 cc. of 0.05 mol. KI soln. to which 5 cc. of commercial 3% H_2O_2 soln. had been added. The influence of various neutral salts on the rate of reaction was also detd. In the latter expts. the concn. of the neutral salt was 1 N. The rate of O evolution was measured by the increase in gas pressure over the soln. A shaking-app. like Brönsted's (cf. *C. A.* 16, 4113) was used. Uni-univalent salts of the type KCl caused a slight acceleration; uni-bivalent salts like K_2SO_4 caused a slight retardation; and bi-univalent salts like $BaCl_2$ caused a marked acceleration. These observations were qualitatively explained as being due to the action of the neutral salt in changing the elec. field in the immediate vicinity of the I^- ion. Further, the temp. coeff. of acceleration of the reaction $H_2O_2 + 2HI \longrightarrow 2H_2O + I_2$ by the H ion was measured, at 0° and 25°, by Harcourt and Essons' classical method (cf. *Phil. Trans.* 157, 117(1867)). The measured velocity const. k , of the equation $-(dC_{H_2O_2}/dt) = kC_{H_2O_2} \cdot C_I(1 + k_1C_H)$ showed a slight decrease with increasing temp. The results when examd. in the light of Herzfeld's concepts (cf. *C. A.* 15, 1440) indicate that the primary reaction is probably $I^- + H_2O_2 \longrightarrow I(O)^- + H_2O$ and that the $I(O)^-$ is stabilized by reaction with H^+ according to the equation $I(O)^- + H^+ \longrightarrow HIO$.

R. L. DODGE

The mechanism of the reaction between iodine, the iodide ion and hydrogen peroxide. J. A. CHRISTIANSEN. *Z. physik. Chem.* 117, 448-56(1925); cf. preceding abst.—An attempt is made to reconcile Brode's conception of the mechanism of the reaction between I, the I^- ion and H_2O_2 (cf. *Z. physik. Chem.* 37, 257(1901); 49, 208(1904)) with Abel's exptl. results (cf. *C. A.* 15, 199) by means of a somewhat involved reaction-scheme. Bray and Livingstone's measurements of the reaction between HBr and H_2O_2 are similarly treated. No new exptl. data are given. R. L. D.

Chemical reactions in powdered mixtures of two kinds of crystals. G. TAMMANN. *Z. anorg. allgem. Chem.* 149, 21-34(1925).—In the introduction to an extraordinarily comprehensive series of exptl. studies are considered the direction of the reaction (that only in which heat is evolved), the reaction kinetics and the dependence of the velocity of thickening of the layer formed from interaction between 2 kinds of crystals upon the orientation of the 2 crystals, the thickness of the layer, the temp. and the nature of the new layer, the atomistics of the linear velocity of reaction in the cryst. lattices, the isothermal transformation in powdered mixts. as it depends upon grain size, the temp. interval on the heating curve of the course of the reaction, the influence of small amts. of liquid in powdered mixts., the temp. of the observed beginning of the reaction and that of the change in position of the mols. **I. The reactions of WO_3 and MoO_3 on basic oxides and carbonates.** G. TAMMANN AND FR. WESTERHOLD. *Ibid.* 35-46.—The heating curves for 26 mixts. of WO_3 and MoO_3 with CuO, BeO, MgO, CaO, BaO, PbO, CeO_2 , $CaCO_3$, $SrCO_3$, $BaCO_3$, FeO, Fe_2O_3 , Al_2O_3 and $CeO_2 + SiO_2$ are reproduced. The relation (heat of formation per mol. \times transformation in mols.)/(sizes of surfaces between 2 heating curves) = const. holds within 5%. Similarly the thickness of the layer of the reaction products of a double pastille follows the law $l = a \log t + b$, and also the transformations in % a law of similar form. The grain size has a large effect; e. g., CuO + WO_3 , diam. of particles 0.007 mm., transformation 98.9%; 0.30 mm., 82.3%; 1.00 mm., 24.0%. **II. Double decomposition of basic oxides with sulfates and nitrates.** G. TAMMANN AND B. GARRE. *Ibid.* 46-58.—Curves and data as above are given for reactions of BaO, SrO, CaO and PbO with sulfates of Zn, Pb, Cu, Ag, and Mg, and $AgNO_3$; of Na and K carbonates with $BaSO_4$ and $PbSO_4$; of Ag_2CO_3 and Na halides; of CaO and PbO with SiO_2 as quartz and as glass. **III. Reactions between oxides and sulfides.** G. TAMMANN AND ERNST KORDES. *Ibid.* 58-68.—The reactions $ZnS + CdO$, $ZnS + PbO$, $ZnS + CuO$ and $PbS + CdS$ are studied with particular reference to the influence of speed of heating, and compression of the pastilles, both of which ordinarily have small effect on the yield. Similarly the reaction between powdered metals and oxides and salts permits a study of the relationship between the temp. of agglomeration and the m. p., the former being 0.57 of the latter when expressed as °abs. Hedvall's work, (*C. A.* 19, 768, 915) is verified. **IV. The behavior of V_2O_5 , SiO_2 , TiO_2 , ZrO_2 , Sb_2O_3 and As_2O_3 with basic oxides.** G. TAMMANN AND H. KALSING.

Ibid 68-89.—The reactions of 12 basic oxides with these anhydrides are summarized in an extensive table (p. 88). **V. Thermodynamics of the reactions in mixtures of two kinds of crystals.** G. TAMMANN. *Ibid* 89-98.—A mathematical discussion in terms of the thermodynamic potential ζ function. For addn reactions $\zeta = E - \eta T + vp$, where E is the molar energy const., η = mol entrop., and v = molar vol. Then $(m\zeta_A + n\zeta_B)/(m + n) \leq \zeta_D$ det's the direction of the reaction, where m and n are nos. of mols. of A and B uniting to form a third type D. Double decompns. are similarly considered.

J. A. WILSON

Secondary kinetic salt effect in the case of hydroxyl-ion catalysis. J. N. BRÖNSTED AND C. V. KING. *J. Am. Chem. Soc.* 47, 2523-31 (1925).—The term "secondary kinetic salt effect" indicates a kinetic salt effect due to a change in concn. of the reacting mols. resulting from to a change in the inter ionic forces. The presence of salts influences OH-ion catalysis when this ion enters into a displaceable homogeneous equil. Data of Arrhenius (*Z. physik. Chem.* 2, 284 (1888)) on the sapon. of AcOEt by ammonia-ammonium buffers show a considerable secondary salt effect. By means of special app. for measuring velocities of reactions accompanied by evolution of gas, the decompn. of nitroso-triacetoneamine into phorone and N has been studied under different conditions. Catalyzed by a strong base the reaction shows a negative primary salt effect. The same reaction measured in a piperidine-piperidinium ion buffer and a phosphate buffer shows a considerable secondary salt effect, positive in the first and negative in the second case, effects which are in agreement with the theory of this effect. These results exemplify the inadequacy of stating an ion-equil. const. without reference to the sp. region of salt concn. to which it applies.

JAMES M. BELL

The promoter action of thoria on nickel catalysts. WM. W. RUSSELL AND H. S. TAYLOR. *J. Phys. Chem.* 29, 1325-41 (1925).—The reaction $\text{CO}_2 + 4 \text{H}_2 = \text{CH}_4 + 2\text{H}_2\text{O}$ is a surface reaction, strongly affected by the adsorbing power of the catalyst surface for the reactants. The activity of Ni alone as catalyst, either supported or unsupported, is greater the lower the temp. at which the Ni was reduced, presumably because the no. of highly unsatd. Ni atoms per vol. of catalyst is greater the lower the temp. of reduction. Heating a catalyst above the temp. at which it was reduced markedly reduces its activity because the increase in the mobility of the atoms with temps. brings about the coalescence of the unsatd. atoms with loss of effective adsorptive power. The primary function of ThO_2 as promoter with supported Ni catalysts is to make possible the existence of a greater no. of Ni atoms of a highly unsatd. character per unit of catalyst, through the creation of ThO_2 -Ni interfaces. With unsupported Ni catalysts, ThO_2 may function as promoter (a) by the creation of a more active surface through the above interface mechanism, (b) by an increase in the extent of surface inasmuch as the promoter acts as a support, (c) by a favorable alteration in the ratio in which the reacting substances and possibly the products are adsorbed. The conclusions are based on the results of both adsorption and reaction-velocity measurements on samples of promoted and unpromoted, supported and unsupported Ni catalysts.

F. L. BROWNE

Heterogeneous equilibrium between tungsten and oxygen and also water vapor at high temperatures. H. ALTERTHUM AND F. KOREF. *Z. Elektrochem.* 31, 508-11 (1925).—A reinvestigation of the work of Wohler (C. A. 17, 2985) taking into account the presence of oxides in the gaseous phase. The heats of vaporization of the oxides WO_2 , W_2O_6 , WO_3 , were calcd. by the modified Trouton's rule $\lambda = 7.4T_s \log T_s$, T_s being observed from the beginning of the Tyndall effect. The equil. const's. were calcd. from the Nernst heat theorem; the ability of O_2 to attack W decreases with rising temp., but the reaction of water vapor increases with rising temp.

G. L. CLARK

The system Na_2SO_4 - Na_2Cl_2 - MgSO_4 - MgCl_2 - H_2O . H. J. ROSE. *Trans. Roy. Soc. Can.*, Sec. III (3) 19, 33 (1925).—Great difficulty in attaining equil. between the constituents of a satd. soln. of thenardite, mirabilite and astrakanite at 25° was experienced. The satd. solns. contain 11.6 moles MgSO_4 , 26.0 moles Na_2SO_4 and 26.3 moles Na_2Cl_2 per 1000 moles H_2O .

J. W. SHIPLEY

The interferometer method for the study of systems of two volatile liquids. G. I. HOOVER AND C. Q. GLASSEY. *Trans. Roy. Soc. Can.*, Sec. III (3) 19, 35 (1925).—The systems $\text{C}_2\text{H}_5\text{OH}-\text{H}_2\text{O}$, $\text{CH}_3\text{OH}-\text{H}_2\text{O}$ at 39°, 76° and 39°, 90° resp. were studied. The results of Vrevskii (C. A. 7, 926), were reproduced.

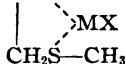

J. W. SHIPLEY

The establishment of the temperature scale to -193° by means of platinum resistance thermometers. A. G. LOOMIS AND J. E. WALTERS. *J. Am. Chem. Soc.* **47**, 2851-6 (1925).—The method of calibration proposed by Henning (*C. A.* **18**, 3522) is shown to be applicable to a Pt resistance thermometer of the calorimeter type. F. R. B.

A simple method for the indirect determination of molecular heats of vaporization. J. NARBUTT. *Z. Elektrochemie* **31**, 511-2 (1925).—A Beckman ebullioscopic app. is simply adapted with suction and open-end water manometer to obtain data, accurate to 0.2%, for substitution in the equation $\lambda = (RT^2/p)(dp/dT)$, where λ is the mol. heat of vaporization, T the abs. boiling temp. at pressure p , and the differential the change in temp. with pressure in the app. GEORGE L. CLARK

Thermal conductivity and thermoelectromotive force of single metal crystals. P. W. BRIDGMAN. *Proc. Nat. Acad. Sci.* **11**, 608-12 (1925).—Plots of the reciprocals of the exptly. detd. thermal conds. against the sp. elec. resistance in the same direction through single crystals of Sn, Bi, Cd, Zn, seem to show a straight-line relationship according to the theory of Voigt. The best straight line through the points does not go through the origin, showing that the Wiedemann-Franz law cannot hold for all directions in a crystal. The thermal e. m. f. between crystal rods of different orientations and Cu was shown to be expressible as $E = at + (t^2b/2)$, where t is $^{\circ}\text{C}$. The coeffs. a and b were obtained as functions of the directions in the crystal. The Thomson heat is shown to be a linear function of the sp. resistance, while the Peltier heat is not. S. K. ALLISON

Researches on residual affinity and coördination. XXIV. Heats of chelation of α -thiolated metallic halides. G. T. MORGAN, S. R. CARTER AND WM. F. HARRISON. *J. Chem. Soc.* **127**, 1917-25 (1925).—S when combined in the form of chelides such as dimethyldithioethylene, $\text{CH}_3\text{SCH}_2\text{CH}_2\text{SCH}_3$ (A) has a remarkable tendency to form complexes of the type $\text{CH}_2\text{S}-\text{CH}_3$, where M is a metal and X an halide. The following

complexes were prepd. by treating a soln. of the salt in the first named solvent with A. A. ZnCl_2 , white crystals, m. $131-2^{\circ}$, slightly sol. in ether, sol. in AcMe, decompd. by H_2O and EtOH. A. ZnI_2 , small white crystals, m. $169-70^{\circ}$, slightly sol. in ether, sol. in AcMe, MeOH and EtOH. A. CdCl_2 , colorless needles, m. 285° , sol. in EtOH, MeOH, insol. in AcMe, slowly decompd. by H_2O . A. CdBr_2 , colorless needles, m. 285° , sol. EtOH, MeOH, ether and acetone. A. CuI (prepd. by adding KI and A to soln. of CuSO_4 in water satd. with SO_2), pale yellow ppt., m. (with decompn.) 156° , insol. in water and ordinary org. media. The heat of the reaction $\text{A} + \text{MX} = \text{A MX}$ was measured and is given in kcal. after the formula for the salt: A. Cu Cl_2 , 14.85; A. CuI , 5.88; A. ZnCl_2 , 13.19; A. ZnBr_2 , 15.35; A. ZnI_2 , 14.18; A. CdCl_2 , 12.16; A. CdBr_2 , 11.27; A. CdI_2 , 9.96; A. HgCl_2 , 13.23; A. HgBr_2 , 11.33; A. HgI_2 , 4.83; A. SnCl_4 , 28.06; A. SnBr_4 , 19.40; A. SnI_4 , 16.58; $\text{A}_3(\text{BrI}_3)_2$, 12.0. These heats are often greater than the heat of formation of the sulfides from the elements. The following subsidiary heats of soln. were measured: SnI_2 in 200 parts CCl_4 , -3.81 ; SnBr_4 in 200 parts CCl_4 , -3.15 ; SnCl_4 in 200 parts CCl_4 , $+0.87$; HgI_2 in EtOH, -2.1 ; HgBr_2 in EtOH, 0.0. F. R. B.

Correction of the thermochemical data of A. Valeur. W. SWIENTOSLAWSKI AND (MLLE.) H. STARCZEWSKA. *J. chim. phys.* **22**, 399-401 (1925).—The heats of combustion of benzoquinone, β -naphthol and anthraquinone as detd. by S.'s standard procedure are 6074.8, 8238.2 and 7422.6 cal. per g. in air at const. vol., resp. With these values as norms the heats of combustion of numerous quinone derivatives as given by Valeur are corrected and tabulated. The correction amts. to -0.26% . F. R. B.

Note on the errors introduced in certain thermochemical determinations and on the coefficients of these determinations. W. SWIENTOSLAWSKI. *J. chim. phys.* **22**, 391-4 (1925).—The types of systematic errors likely to be present in older detns. of the heats of combustion are listed and directions are given for the correction of such results in terms of modern norms. F. R. BICHOWSKY

Correction of the thermochemical data of P. Lemoult. W. SWIENTOSLAWSKI AND M. POROW. *J. chim. phys.* **22**, 395-8 (1925).—The heats of combustion of naphthalene, β -naphthylamine and p -aminoazobenzene as detd. by S.'s standard procedure, are 9612.9, 8812.5 and 7983.7 cal. per g. in air at const. vol., resp. With these values as norms the heats of combustions of numerous amines as given by Lemoult are corrected and tabulated. The correction amts. to -0.521% . F. R. B.

Calorific value and constitution. M. F. BARKER. *J. Phys. Chem.* **29**, 1345-63 (1925).—The following heats of combustion were detd.; benzene 783.4, toluene 941.3,

xylene 1091.3, naphthalene 1238.0, biphenyl 1500.0, phenol 733.0, *o*-cresol 883.7, *p*-cresol 885.0, *m*-cresol 883.0, benzyl alc. 890.0, pyrogallol 618.1, *o*-, *m*-, *p*-dihydroxybenzene 684.9, 683.9, 684.7, benzoin 1670.8, benzil 1621.6, furoin 1114.0, furil 1064.4, lepidene 3288.4, *p*-nitroacetylbenzoin 1864.4, *p*-nitrobenzil 1600.9, *p*-nitrobenzoylbenzoin 2443.4 kcal. per mol. at const. pressure. Details of exptl. procedure and accuracy are not given. Following the usual argument the heats of combustion of the following groups are calcd. =CO 60.7; —OH 12.9; —C=C— 97.7; —C≡C— 122.0; (by a comparison with trimethylene the following structure for these bonds is proposed: —CΔC—, —C⊕C—); —H 69.3, (same as free H in H₂); —C = (in benzene) 97.0;

—C< (in side chains) 82. The value for —C— depends on the angle between the linkages; that of the —COOH group is not that calcd. from its formula but suggests a structure $\text{X}-\text{C} \begin{matrix} \text{OH} \\ \diagup \\ \text{OH} \end{matrix}$. The prism formula for benzene is in best agreement with the data on the hydrogenation of benzene.

F. R. B.

Establishing the heat of combustion of calorimetric standards. Remarks on a paper by Jaeger and v. Steinwehr. P. F. VERKADE AND J. COOPS. *Z. physik. Chem.* **118**, 123-8(1925).—The values adopted for the heat of combustion of benzoic acid, sugar and naphthalene by the "Commission pour l'établissement d'un étalon thermochimique" in 1922 are based on all data published up to that time; hence, the criticism of Jaeger and v. Steinwehr (*C. A.* **19**, 1085) that the results obtained at the Reichsanstalt have not been given consideration is unfounded. Bibliography. F. C. K.

Heat of solution of gypsum in the region of maximum solubility. F. LANGE AND F. DÜRR. *Z. physik. Chem.* **118**, 129-39(1925).—Thermodynamics of solns. yields the expression $(d \ln c/dT)(f_0 + c(df_0/dc)) = -L/RT^2n$. L is the last heat of per mol. soln.; in the case of sparingly sol. substances this may be taken as practically equal to the total heat of soln. f_0 , c and n are the osmotic coeff., concn. of solute in moles/l., and no. of atoms per mol. of solute, resp. Since $f_0 + c(df_0/dc)$ is not likely to be zero in case of a sparingly sol. substance, $L = 0$ must correspond to the condition that the soly of the substance is either max. or min. Data of Hullett and Allen (*J. Am. Chem. Soc.* **24**, 667(1902)) show that CaSO₄·2H₂O has a max. soly. in the neighborhood of 35°. Direct measurements of the heat of soln. at 22.5°, 27.8°, 33.4° and 37.6° yield $L = -590, -300, \pm 0$, and 230 cal./mol., resp., confirming the above prediction. The accuracy of the measurement of L is about 40 cal./mol.

F. C. KRACEK

The passivity of nickel. FRITZ EISENKOLB. *Z. Elektrochem.* **31**, 503-7(1925).—Detns. of the passivification of Ni in oxygen acids give the same value of the transition potential which is only to a very slight extent dependent upon concn. The other metals of the Fe group are not analogous. The passivity of Fe and Ni was studied in H halide acids, in mixts., in order to study effects of the anion, and with rotation of the electrodes. There is no difference in numerical value between active and passive metal.

GEORGE L. CLARK

Saturated standard cells with small temperature coefficients. W. C. VOSBURGH. *J. Am. Chem. Soc.* **47**, 2531-40(1925).—By substituting for the Cd-amalgam electrode of the normal Weston cell a Cd-Sn-amalgam electrode the e. m. f. was increased from 1.01805 to 1.01901 v. at 25°, and the temp. coeff. was decreased to about 2/3 that of the normal Weston cell. The cell thus formed was as reproducible and as nearly const. over short periods of time as the Weston cell. There is no reason to expect any greater variability over long periods of time. A similar cell with a Cd-Pb-amalgam electrode had an e. m. f. of 1.01918 v. at 25° and a higher temp. coeff. than the cell contg. Sn. The presence of Pb in a Cd amalgam increased the tendency for the reaction of the Cd with H ion of the electrolyte. In both these cells the e. m. f. was equal to the sum of the e. m. fs. of the Weston cell and an amalgam cell with one electrode of pure Cd amalgam and the other a Cd amalgam contg. Sn or Pb. Similar amalgam cells with Bi in one amalgam gave an e. m. f. of 1.01976 v. at 25° and with a positive temp. coeff. equal to the negative temp. coeff. of the similar cell with a Cd-Sn-amalgam electrode. Amalgam cells in which one electrode contained Cu had an e. m. f. of only about 10 mmv. and showed that the presence of Cu in the amalgam of a Weston cell would not appreciably alter the e. m. f. or temp. coeff.

JAMES M. BELL

Concentration electromotive force in solutions containing acid. A. R. GORDON AND C. WEBER. *Trans. Roy. Soc. Can., Sec. III* (3) **19**, 26-7(1925).—The p. d. across a liquid surface sepg. 2 air-free CuSO₄ solns. in max. conducting H₂SO₄ can be expressed by P. D. = $IR + B' \ln Z_0/Z$, in which Z_0 and Z are the concns. of the Cu ions and B'

is the Nernst factor ($RT/2F$). For Cu_2Cl_2 in 3 N HCl and Ag_2SO_4 in N H_2SO_4 $B' = RT/F$. The transport no. for Ag in 0.025 N soln. is 0.023 and for 0.0125 N soln. 0.011. J. W. SHIPLEY

A photomicrographic study of the evolution and disappearance of gas during the passage of electricity through glass. J. B. FERGUSON AND O. W. ELLIS. *Trans. Roy. Soc. Can., Sec. III* (3) 19, 34 (1925).—This is a report from a photographic study of the phenomena and verifies the observation recorded in *C. A.* 18, 3303. Glass was found not to behave as a homogeneous medium in respect to the formation and disappearance of gas in an elec. discharge. J. W. SHIPLEY

The electrolysis of soda-lime glass. M. J. MULLIGAN. *Trans. Roy. Soc. Can., Sec. III* (3) 19, 35 (1925).—The elec. migration of Ag from a Ag anode in aq. solns. into glass was observed. Ag from an aq. soln. of AgNO_3 diffused into glass at 100° without the use of the elec. current. J. W. SHIPLEY

Oxidation-reduction potentials of organic substances. I. HANS V. EULER AND ARNE ÖLANDER. *Z. anorg. allgem. Chem.* 149, 1-17 (1925).—After an introductory summary of the theory of oxidation reduction potentials, measurements are given of O_2 electrode potentials (platinized Pt wires referred to a satd. KCl -calomel electrode at 18°) of solns. of different concns. which are buffered by phosphate so as to give p_{H} of 4.15 and 8.0. These solns. are hydroquinone, quinone, MeCHO , $\text{EtOH} + \text{AcOH}$, $\text{EtOH} + \text{AcOH} + \text{MeCHO}$, lactic acid, Na lactate, glucose, fructose, Na benzoate, and K cinnamate. H_2 electrode measurements on buffered hydroquinone solns. are also reported. The value of the O_2 electrode in the phosphate buffer of p_{H} 4.15 is 0.550 v. and of the H_2 electrode is 0.495 v. The value of the H_2 , O_2 chain in 0.5 N acetate mixture ($p_{\text{H}} = 4.15$) is around 0.700 for Au electrodes. D. S. VILLARS

Thermodynamic potential differences at the boundary of two liquid phases. II. SERG. VOZNESENSKII. *Z. physik. Chem.* 117, 457-60 (1925); cf. *C. A.* 19, 3204.—Cells of the type $\text{Ncalomel} | \text{acid} + \text{KOH} | \text{acid} + \text{KOH} | \text{KCl} | \text{Ncalomel}$ in H_2O | in AmOH | AmOH | electrode were made up with H_3PO_4 or citric acid concn. of 50 millimoles per l., and KOH concns. of 0 to 100 millimoles per l. in the aq. phase. Breaks were found in the e. m. f./concn. of KOH curves corresponding to the formation of primary, secondary and tertiary salts. Cells with N KCl in H_2O and AmOH between N calomel electrodes, with varying amts. of butyric or valeric acid added showed no e. m. f. in case of the latter acid, and only a small value with butyric acid at concns. greater than approx. 400 millimoles/l. in the aq. phase. F. C. KRACEK

Some electrode phenomena in electrolysis. J. A. CROWTHER AND R. J. STEPHENSON. *Phil. Mag.* 50, 1066-79 (1925).—A contact or interface resistance exists between an electrolyte and a polarizable electrode. The resistance is inversely proportional to the total pressure on the cell, from which it is deduced that a thin gas film is responsible for the resistance. If the e. d. exceeds a crit. value the resistance of the electrolyte is largely increased. Possibly the liquid is thrown into the spheruloid state by the heat generated in the contact resistance. S. C. L.

The magnetic susceptibility of rubidium bromide, cesium iodide, krypton and xenon. LOUISE CROW. *Trans. Roy. Soc. Can., Sec. III* (3) 19, 63-70 (1925); cf. *C. A.* 18, 1232.—The object was to measure the magnetic susceptibility of 2 compds. differing in the sum of the at. nos. of their constituent elements by unity from that of Kr on the one hand and from that of Xe on the other and then deducing from the results by interpolation the susceptibility of Kr and Xe . The salts RbBr and CsI were placed in glass tubes suspended from a balance and then brought midway between the poles of an electromagnet. The pull in grams due to the magnetic field was measured and compared with that of Hg used in the same tubes and the value for the magnetic susceptibility of Hg at 18° taken as $K = -205 \times 10^{-6}$. Two measurements for CsI gave $K = 78.8 \times 10^{-6}$ and $K = 76.4 \times 10^{-6}$. RbBr gave $K = -62.9 \times 10^{-6}$. On the assumption that the constituent elements were in the ionic condition and that the susceptibility is proportional to the square of the at. nos., for Cs $K = -38.0 \times 10^{-6}$ and -36.8×10^{-6} , for I , $K = -40.8 \times 10^{-6}$ and -39.6×10^{-6} , for RbBr , $K = -29.9 \times 10^{-6}$ and for Br , $K = -33.0 \times 10^{-6}$. Interpolation gives for Kr $K = -31.5 \times 10^{-6}$ and for Xe $K = -38.2 \times 10^{-6}$ and -39.4×10^{-6} which, expressed as vol. susceptibilities at 20° and 760 mm are -13.1×10^{-10} for Kr and a mean of -16.2×10^{-10} for Xe . The magnetic susceptibility of the pure alkali metals K , Rb and Cs measured with the same app. gave for K -1.9×10^{-6} , for Rb -7.0×10^{-6} and for Cs -8.0×10^{-6} at 20° . J. W. SHIPLEY

The scattering of light by anisotropic liquids. W. H. MARTIN. *Trans. Roy. Soc. Can., Sec. III* (3) 19, 36-8(1925); cf. *C. A.* 19, 779.—*p*-Azoxyanisole between its m. p., 116°, and 135° is a turbid liquid exhibiting in its optical properties a disordered mass of uniaxial crystals. After filtering through a Mandler diatomaceous earth filter its depolarization factor, with white light and a combination of the Wollaston and Nicol prisms, was found to be 0.85. This value corresponds to that of a liquid compd. of mols. in which vibration can occur in only one direction, that is of needle-shaped mols. The value of 0.85 was almost independent of the color of the exciting light. J. W. S.

Light scattering of "abnormal" liquids. O. C. H. KITCHING. *Trans. Roy. Soc. Can., Sec. III* (3) 19, 30(1925); cf. *C. A.* 18, 20.—Dust-free org. liquids were prepd. by filtration through Mandler diatomaceous filters. Light scattering of aniline, phenol and acetaldoxime at temps from 20° to 100° was measured relative to C_6H_6 and the results were compared with calcd. values. Aniline and phenol behaved as normal liquids but acetaldoxime gave a value double that calcd. and the temp. coeff. was about $1/4$ the calculated value. This deviation is explained on the assumption of equil. between the stereoisomers. J. W. SHIPLEY

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

Advances in photochemistry. W. MEIDINGER. *Z. angew. Chem.* **38**, 1029-32 (1925). E. J. C

The structure of the hydrogen molecule ion. H. C. UREY. *Proc. Nat. Acad. Sci.* **11**, 618-21(1925).—The energy is calcd. of the steady state in which the electron vibrates in a straight line perpendicular to the middle point of the line joining the nuclei. The energy equation is $W = -Rhc_1 (1/n^2) 1.2300$, where R is the Rydberg const., h Planck's const., c_1 the velocity of light and n the quantum no.; and $2c/a = 1.051n^2$, where c is $1\frac{1}{2}$ the distance between nuclei and a = the radius of the first Bohr orbit for H. The calcd. ionizing potential is 16.65 v., agreeing well with the observation of Olsen and Glockler. Secondly the heat of dissociation and the moment of inertia calcd. agree with exptl. data. The theory predicts that there should be an ultra-violet spectrum belonging to H_2^+ between 850 and 741 Å. U. G. L. CLARK

Structure of the elements of the iron series in the periodic system. M. A. CATALAN. *Anales soc. españ. fis. quim.* **23**, 395-408(1925); cf. *C. A.* **19**, 610.—The arc and spark spectra show a similarity between the first 5 and the second 5 elements 19 K to 28 Ni. The azimuthal quantum number of the fundamental levels is the same for the corresponding elements, the multiplicity of these terms rising up to Mn and falling thereafter. The principal of selection elaborated by Russell and Laporte is discussed. C. proposes to change the Russell designation "ultimate and penultimate lines" to "primary and secondary lines." Certain regularities are found between the resonance lines and multiplicity of their terms, also between the Gaumont *raies ultimes* for these elements. The empirical rule that the *raies ultimes* are always found in multiplets of the type $k \rightarrow k + 1$ given by Meggers is explained. In arc and spark spectra the terms are regular when the multiplicity is rising, are inverted if the multiplicity is falling, and there are both regular and inverted terms when the multiplicity has reached a max. or a min. E. M. SYMMES

Chemical statics of electronic phenomena. L. ROLLA AND G. PICCARDI. *Atti accad. Lincei* [6], **2**, 29-31, 128-32, 173-7(1925).—The ionization of an atom according to the scheme: $A \rightleftharpoons A^+ + \text{electron}$, is considered as an ordinary chem. reaction to which the law of mass action and van't Hoff's formula are applicable. This hypothesis

of Meg Nad Saha (C. A. 15, 468, 799, 1452) that has such important applications in astrophysics lacks direct exptl. proof, although King (C. A. 16, 3255) has supplied qual. evidence in its support. Because of its importance this reaction merits further study and R. and P. have undertaken a quant. exptl. study. A fine metallic thread placed in a flame and at red heat emits electrons. In a flame contg. an atomic species A the reaction $A \rightleftharpoons A^+ + \text{electron}$ takes place and A^+ ions and electrons will be present. The ions remain near or strike against the wire and their charges are neutralized by taking an electron from the metal itself. The electrons remain free in the flame. If these free electrons are collected and are carried away from the incandescent wire a continuous electronic current is obtained. The intensity of this current will be a function of the no. of electrons that pass in a unit of time and more precisely by admitting that $e = 4.774 \times 10^{-10}$ electrostatic units, the current due to 1 electron is 15.84×10^{-20} amp. The no. of electrons is equal to the no. of ions per sec. according to the above reaction and the concn. $[A]$ can be calcd. easily from the wt. of the substance volatilized per unit of time and from Avogadro's no. ($6 \times 10^{23} = N$). One is thus able to calc. the dissoen. const. and the equil. const. of the above reaction. Various systems for collecting the current were tried. The best results were obtained by using a fine wire to generate the electrons, which were collected on a thin plate. These devices are illustrated and described in detail. A weighed pearl of the salt of the metal in question is introduced into the flame on the wire and the current produced at any instant is measured with the galvanometer. The diagram obtained is integrated graphically to obtain the av. total current. The numerical quant. data are given in tables and graphs. From the loss in wt. of the pearl and the other data $[A]$, $[A^+]$, and $[e]$ are obtained $X = \% \text{ dissoen.} = 100 \frac{[A^+]}{[A]}$ and $K = \text{equil. const.} = \frac{[A^+][e]}{[A]}$.

The applicability of the law of mass action to these phenomena was demonstrated. On the basis of the values K for the equil. const. the heat of ionization and the ionization potential can be calcd. With Na this was found to be 116,000 cal (Franck Hertz, (C. A. 11, 2556; 13, 2483) found 117,000 cal.) or expressed in v. $U = 5$ (instead of 5.1 v.). In expts. with Rb, K, Na, Li, Ba, Ca, Tl, Cu, B and P at temps. 1100–1500° only those elements having an ionization potential below 8 v. were appreciably ionized. All elements constituting the acid radicals of salts have very high ionization potentials, generally above 10 v., and consequently at the temp. of these expts. these elements do not give rise to an appreciable electronic current. The current produced is thus due only to the products of ionization of metallic atoms (cf. Arrhenius, *Ann. Phys.* 43, 18(1891)). The relation between the ionization potential and the chem. function of the elements is discussed in the last paper. The ionization potential is independent of the temp. (at least under the conditions used) and so by integrating the formula that expresses the law of mobile equil. the linear law $\log K = -U/RT + C$ is obtained that gives $\log K$ as a function of U when T is const. (C is a const. of integration). If now U is known for 2 different elements the values of $\log K$ can be detd. experimentally for the 2 elements and then the coeffs. of this equation can be calcd., valid for the conditions selected. Once these coeffs. are known U can be calcd. for other elements by detg. the value of $\log K$ experimentally. That this equation is applicable is shown by data given. The divergencies between the predicted value for the ionization potential and the observed potential detd. in the other way is of the order of tenths of a volt. The ionization potentials of 4 elements were detd. in this way. The values follow: Ba 5.1 v. (5.19 v.), Sr 5.6 (5.67 v.), Mo 7.1 v. (7.35 v.), Cu 7.6 v. (7.8 v.). The values in parentheses had been calcd. from spectroscopic data. This method is preferable from the exptl. point of view to the one described above for rapidity of work and accuracy and certainty of results.

E. J. WITZEMANN

The excitation energy necessary for atomic disintegration. ADOLF SMEKAL. *Naturwissenschaften* 13, 800–1(1925).—From data of Kirsch (C. A. 19, 3212) on the const. difference $E_1 - E_2$ ($= 15 - 16 \times 10^{-7}$ ergs) between the energy E_1 necessary for temporary union of a N nucleus with an impinging α -ray particle and the energy E_2 liberated on emission of a H particle from the (N + α) nucleus, S. concludes that (although the suppositions of Kirsch are rather uncertain yet) the resulting O-isotope, O^{17} , apparently has this difference as a quantized energy amt. at its disposal. It represents the excitation energy for the disintegration process and corresponds to a min. range of 4.6 mm. of the α -rays.

B. J. C. VAN DER HOVEN

The behavior of lead containing radium in the formation of formaldehyde according to Thunberg. A. SROLFI. *Atti accad. Lincei* [6], 2, 195–7(1925).—Thunberg (C. A. 18, 848) has recently stated that the photochem. reduction of CO_2 proceeds thus $2H_2O + \text{solar light} \rightarrow H_2 + H_2O_2$. The H_2 evolved and the H_2O_2 react thus: $CO_2 +$

$\text{H}_2 + \text{H}_2\text{O}_2 \rightarrow \text{H}_2\text{CO}_2 + \text{O}_2$ and $\text{H}_4\text{CO}_2 \rightarrow \text{HCHO} + \text{H}_2\text{O}$. T. reduced CO_2 of basic Pb carbonate in this way. S. decided to det. whether basic Pb carbonate contg. Ra G would behave differently in this reaction from basic Pb carbonate prepd. from ordinary Pb. Cotunnite (PbCl_2) was used from a vesuvian fumarole known to be radioactive by reason of radio-Pb (Zambonini, *Atti accad. Lincei*, **16**, 1, 975(1907); Rossi, *Atti accad. Lincei*, **16**, 1, 630(1907)) of which the at. wt. is 207.05 (Piuetti, Migliacci, *Accad. Sci. Fis. e Mat., Napoli* 1925). The expts. were carried out according to the directions of T. The presence of Ra G caused no difference in the formation of CH_2O in comparison with ordinary Pb. E. J. WITZEMANN

A determination of the variation of the mass of the electron with velocity, using homogeneous β -rays. R. A. R. TRICKER. *Proc. Roy. Soc. (London)* **109A**, 384-96 (1925).—The variation of the mass of the electron with its velocity is detd. by a method consisting in the acceleration of the "line" β -rays from RaB and RaC in a focusing app. The accuracy is of a similar order to that in the expts. of Bucherer (*Ann. Physik* **28**, 974(1909)). The results, with rays of velocity up to 0.8 that of light, agree with the theory of relativity within the limits of exptl. error. G. L. CLARK

The absorption coefficient for slow electrons in the vapors of mercury, cadmium and zinc. R. B. BRODE. *Proc. Roy. Soc. (London)* **109A**, 397-405(1925).—The absorption coeff., or the effective area of a mol. within which an electron is deflected, was measured for electrons from 0.4 to 50 v. velocity in the vapors of Hg, Cd and Zn. Except for the change below 4 v. in Cd, and the small drop in Hg below 3 v., the curves are approx. hyperbolas of the same size. There are no indications of long free paths at low velocities. The sudden decrease in the absorption coeff. above the ionization potential, when measured at low pressure, is due to the effect of the ions in the emission of the filament and not to a true change in the absorption coeff. A type of *valve* is described for closing off the app. *in vacuo* at high temps. G. L. CLARK

Study of electron currents through crystals. B. GUDDEN AND R. POHL. *Physik. Z.* **26**, 481-3(1925).—In his study on the action of temp. upon the photoelec. current in crystals, Lenz (*Physik. Z.* **26**, 365; cf. *C. A.* **19**, 3422) omits the fact that temp. affects the absorption of light by crystals. His measurements at different temps. cannot be compared and do not justify his conclusions. C. CALINGAERT

Scattering of electrons in ionized gases. IRVING LANGMUIR. *Phys. Rev.* **26**, 585-613(1925).—Analysis of the current received by a collector placed opposite a hot cathode indicates that there are 3 groups of electrons present, (1) *primary electrons* which retain practically all the momentum they acquired in passing through the positive ion sheath around the cathode, (2) *secondary electrons* moving in random directions with Maxwellian velocity distribution, (3) *ultimate electrons* having a Maxwellian velocity distribution corresponding to a much lower temp. than the secondaries, and dependent upon the gas present and its pressure. The no. of ultimate electrons is roughly 1000 times the primaries and secondaries for Hg, although relatively less for H_2 . In the uniform positive column of arcs only ultimate electrons are present. Consideration of the no. of collisions of electrons with each other and the high temp. maintained indicates that electrons in low-pressure arcs suffer many changes of momentum during time intervals between collisions. Analysis of the effects to be expected when a beam of primary electrons encounters a cloud of stationary electrons, indicates that the scattering is best accounted for by collisions with a cloud of radiation quanta, a *kind of Compton effect*. The observed scattering is about 10^6 greater than the normal Compton effect would give. D. C. BARDWELL

Relative production of positive and negative ions by electron collisions. F. L. MOHLER. *Phys. Rev.* **26**, 614-24(1925).—Positive or negative ions produced in HCl, Hg, I_2 and HgCl_2 by accelerated electrons were collected by a concentric cylindrical electrode maintained at a potential slightly lower or higher than the axial electron beam. The primary electrons were removed by a solenoidal magnetic field. The expts. give no support to the theory that electrons dissociate polar mols. into positive and negative ions, but are in agreement with the results of magnetic analysis that the primary effect is the production of a positive mol. ion. The negative ion curves indicate that only slowly moving electrons can attach themselves to mols. to form negative ions. D. C. BARDWELL

Ionization of hydrogen by slow electrons. H. KALLMANN AND M. A. BREDIG. *Naturwissenschaften* **13**, 802(1925).—Preliminary report on *e/m* detns. of H ionization products. At 16 v. electron energy H_2^+ ions are primarily formed; these produce secondarily some H ions and more H_3^+ ions, also neutral atoms; possibly some H ions are primarily formed. At higher electron velocities up from 30 v. the number of H

ions increases, corresponding to a second ionization potential (Frank and Krüger) of 29 v.

The nature of the ions from hot platinum. H. A. ERIKSON. *Phys. Rev.* **26**, 625-8 (1925).—The mobilities of the ions produced by hot Pt were obtained by driving the ions across a stream of air by means of an elec. field. The mobilities indicated ions of the same mass as for air.

The mobilities of the ions of the active deposits of thorium and radium. H. A. ERIKSON. *Phys. Rev.* **26**, 629-32 (1925).—Two positive active bodies differing in mobility were found in the active deposits of thorium and radium. It is more probable that the different mobility is due to one body being singly charged and the other doubly charged than that it is due to a deposit of an A product and a B product successively.

Characteristics and spectra of low-voltage arcs in hydrogen, nitrogen and mixtures of hydrogen with mercury and nitrogen. C. T. KWEI. *Phys. Rev.* **26**, 537-60 (1925).—A study was made of the breaking voltage of the arc in a spherical bulb containing a Ni disk electrode and a W filament and provided with a quartz window for spectroscopic examn. With pure H₂, the arc broke at 16.2 v., (its ionization potential) By plotting the 2/3 power of the current against the voltage, the ionization potential of the H at. was located at 13.7 v. With pure N₂, the breaking voltage was 16.2 (its ionization potential is 16.9 v.). In mixts. of H₂ and Hg, two arcking and two breaking voltages were observed, the difference between them being 10.4 v. (the ionization potential of Hg). Mixts. of H₂ and N₂ behaved similarly to the mixts. with Hg. Spectroscopic phenomena accompanying these changes were observed and their meaning discussed.

Ionization in reacting gases. A. K. BREWER. *Phys. Rev.* **26**, 633-42 (1925).—See C. A. **19**, 3423.

The effect of knock inducers and suppressors on gaseous ionization. G. L. CLARK, E. W. BRUGMANN AND W. C. THEE. *Ind. Eng. Chem.* **17**, 1226-9 (1925).—By passing the gas through an ionization chamber, using monochromatic Mo X-rays as the ionizing source, and then through a second chamber containing 2 electrodes 20 cm. apart and each at 113 volts potential difference from the chamber, the relative ionization currents at the 2 electrodes give a measure of the rate of recombination of the gaseous ions. Based on air, the rate of recombination was decreased slightly by C₆H₆ vapor, somewhat more by C₆H₆ and BuONO, but was most decreased by C₆H₆ and PbEt₄. The latter fact does not agree with previous theories as to the action of anti-knock compds. Other theories are briefly discussed and further research is suggested.

Electron conduction in crystals. HERBERT LENZ. *Physik. Z.* **26**, 642-3 (1925); cf. C. A. **19**, 3422; **20**, 10.—A reply to Gudden and Pohl's criticism (C. A. **19**, 1659) of L.'s work on the temp. variation of photoelec. current in crystals, especially diamond and ZnS, it is emphasized that the primary (electron) current decreases as temp. is lowered, all other variables being const. Lenz used the undispersed light from a quartz Hg lamp in contradistinction to the monochromatic radiation considered by G. and P. Seven ZnS crystals used by L. gave the same effect. L. is of the opinion that more data are needed before definite theoretical conclusions can be made. Current excited by cathode rays impinging on the crystals does not vary appreciably with the temp. of the crystal.

The photoelectric threshold for mercury. C. B. KAZDA. *Phys. Rev.* **26**, 643-54 (1925).—Very carefully purified Hg gave a value of 2735 A. U. for the photoelectric threshold corresponding to a work function of 4.52 v.

Variation in the photoelectric emission from platinum. A. E. WOODRUFF. *Phys. Rev.* **26**, 655-70 (1925).

Investigation of photoelectric valve coated with potassium. V. M. ALBERS. *Phys. Rev.* **26**, 671-7 (1925).

Indirectly excited fluorescence spectra. S. LORIA. *Phys. Rev.* **26**, 573-84 (1925).—The expts. of Franck and Cario on the fluorescence spectrum of Tl mixed with Hg vapor were repeated and the previous results confirmed. The enhancing effect of inert gases observed by Donat was confirmed. Evidence is obtained that the metastable Hg atom may survive many collisions with normal A or N₂ mols. but easily gives up its energy when colliding with normal Tl or Hg atoms, probably more easily to Tl than to Hg.

The influence of the surrounding medium on frictional electricity. J. H. JONES. *Phil. Mag.* **50**, 1160-77 (1925).—When electricity is produced on a metal by friction with silk the amt. produced depends greatly upon the material used as a basis for the silk; to ensure a large amt. of electricity the material should not be an insulator, but should

possess an appreciable degree of cond. If a metal is rubbed for a prolonged period with silk, the potential of the metal undergoes fluctuations, which may be due to the silk being rubbed away in layers or to a fatigue of this material similar to that which has previously been observed in ebonite. If a metal is being rubbed by silk in air and if the potential of the metal is low, the introduction of any one of the following gases, coal-gas, H_2 , CO_2 to replace the air, causes the potential to rise. On the other hand, if the potential in air was high, the admission of one of these gases caused the potential to fall. The introduction of SO_2 to replace the air in all cases caused the potential to rise, whether the potential in air was high or low. How far this effect may be due to the superior cond. of this gas has not yet been detd. O_2 , and still more O_3 , always caused a fall of potential as compared with that developed in air. This effect does not appear to be due to leakage through these gases. It is suggested that the fall of potential in O_2 may be due to a partial ozonization of the gas by the field, due to the frictional electricity. The influence of these gases on the amt. of frictional electricity produced is greatest when the silk-rubber is mounted on a metal base. If the air surrounding the rubbing-surfaces is replaced by a liquid medium, the potential of the metal is higher if the liquid possesses appreciable conductivity; ordinary lamp-oil is superior in this respect to pure paraffin. This effect may be partly due to the removal by the liquid of some of the charge on the silk-rubber, as suggested in the case of SO_2 . The effect of a liquid insulator (e. g., paraffin oil) as medium increases with rise of temp. of the liquid up to a certain point. This may be due to the gradual increase of cond. of the liquid. At a certain temp. however, the insulation of the oil appears to break down, and the production of frictional electricity almost stops. The temp. of the rubbed metal surfaces rises almost in proportion to its potential. The metal wheel gives the best result in air, ebonite the poorest, while the ebonite wheel gives the best result in oil, metal the poorest. The order of the gaseous media for the best production of frictional electricity is SO_2 , air, N_2 , coal-gas, H_2 , CO_2 , O_2 , O_3 . Liquid media: crude lamp-oil, pure paraffin. S. C. L.

Quantum theory of the polarization of resonance radiation in magnetic fields. J. H. VAN VLECK. *Proc. Nat. Acad. Sci.* **11**, 612-8(1925).—The resultant polarization due to the superposition of unresolved Zeeman components in light from Na vapor emitting resonance radiation in a magnetic field is calcd. as a function of the angle between the elec. vector of the exciting radiation and the magnetic field and the ratio of the energy of frequency D_1 to the energy of frequency D_2 in the exciting beam. In this calcn. the latest theoretical and exptl. values for the intensities of Zeeman components are used. The results are in fair agreement with recent expts. S. K. A.

Recent researches in positive rays. W. WIEN. *Nature* **115**, 780(1925).—A review. F. N. S.

A new laboratory for precision X-ray research. ALICE H. ARMSTRONG AND W. W. STIFLER. *J. Optical Soc. Am.* **11**, 509-17(1925).—The Cruft High Tension Lab. at Harvard University is described. J. H.

An attempt to test the quantum theory of X-ray scattering. R. D. BENNETT. *Proc. Nat. Acad. Sci.* **11**, 601-2(1925).—An attempt was made to test the angular relations between the recoil electron and the scattered quantum by using Geiger counters mounted on a divided circular scale. It was also desired to discover whether the registration of a scattered quantum is simultaneous with the registration of a recoiling electron at the correct angle. Definite results were not obtained, because of (1) the occurrence of coincidences in groups, (2) the time lag in the point counters. Work is being continued. S. K. ALLISON

X-rays from a ruled reflection grating. A. H. COMPTON AND R. L. DOAN. *Proc. Nat. Acad. Sci.* **11**, 598-601(1925).—An X-ray beam fell on the surface of a speculum metal grating, ruled lightly with a grating space of 2.000×10^{-3} cm. The grazing angle of the beam was less than 25 min. of arc, and in this range total reflection takes place. If the grazing angle on the grating face is less than a certain limiting angle, spectra appear on both sides of the totally reflected beam, which constitutes the zero order. Such spectra were obtained from Cu and Mo targets, also from the Mo $K\alpha$ line as reflected from a crystal. The weighted mean value of measurements on five films showing 1 to 4 orders of the Mo $K\alpha$ line is $\lambda = 0.707 \pm 0.003$ A. U. It is hoped to increase the accuracy of the method so that absolute measurements can be made with the same accuracy as that to which the grating space of calcite can be measured. S. K. ALLISON

The fine structure of certain X-ray absorption edges. KATHERINE CHAMBERLAIN. *Phys. Rev.* **26**, 525-36(1925).—See C. A. **19**, 1534. D. C. BARDWELL

The Michelson-Morley experiment. ALFRED DANIELL. *Nature* **115**, 378-9(1925).—On the basis of a "precise single ray" D. calcs. that there should have been

no interference effect in the M.-M. expt. unless the instrument were in rapid motion. The idea is severely criticized by Olijer Lodge.

Optical and magnetic rotatory dispersion. Dispersion, density and absorption spectra of chemically homologous substances. ALFRED KRITHLOW. *Z. wiss. Phot.* 23, 233-82(1925).—An extensive survey of the literature on natural and magnetic rotatory dispersion reveals the need of an adequate expression to connect the dependence of these properties on concn. and wave length. The classical law of Verdet, stipulating lack of dependence of sp. magnetic rotation on concn., as well as Wiedemann's law, demanding proportionality between these factors, are not in accord with recent measurements. K. has made a critical study of a series of 8 homologous mothylenecamphor derivs. in the hope of shedding light on these relations. The expts. as carried out necessitate a clear distinction between "natural" and "magnetic" rotatory dispersion. Natural rotatory dispersion is definitely related to concn. and hence Verdet's const. $R = \alpha'/Hl \cos \beta$ can be calcd. directly from the exptl. magnitudes. α' is the magnetic rotation in mins. (obtained from measurements of the rotation of the plane of polarization in a magnetic field); l is the length of absorbing column; H is the field strength (directly proportional to the current passed through an electromagnet with and without Fe cores); β gives the angular deviation of the light rays in the direction of the field. Values of α' and β are tabulated in degrees for different current strengths and for wave lengths in the range 6548-4861 Å. U. Similar data are recorded for C₁₀H₈ solns. of Al₂Cl₆. Hagenbach's formula $\alpha = A\nu^2 + B\nu^4 + \dots$ (C. A. 9, 1872) is found valid for homologous series, although the more general relation $\alpha = C(\phi)\lambda$ is in better agreement with the data. Since the magnetic rotation bears no definite relation to concn. of the soln., K. has proposed the formula $\alpha = [K_1/(\lambda^2 - \lambda_1^2)] - [K_2/(\lambda^2 - \lambda_2^2)]$, which is an elaboration of Drude's original equation. Dispersion curves calcd. on this basis are characteristically different for simple, complex and anomalous absorption. Cotton's phenomenon (anomalous rotation in the visible region) has been confirmed for the 21 substances investigated (cf. C. A. 15, 501).

H. R. MOORE

Measurement of the dispersion of carbon disulfide in the ultra-violet. G. BRUHAT AND M. PAUTHENIER. *J. phys. radium* 6, 287-94(1925).—See C. A. 19, 1819. H. G.

A spectral white-light filter. HELMUT NAUMANN. *Z. wiss. Phot.* 23, 303-19 (1925).—The requirements of an artificial light source modified to give an impression of daylight are discussed. Thus a simplified modification of Wien's formula $E = C \lambda^{-5}/e^{\lambda T}$ affords a theoretical basis for computing the ratio between the temp. T_1 of the continuously radiating source and the transmitted brightness T_0 . Calcn. of the energy curves for both temps. serves as a guide for estg. the optimum thickness of the filters and other exptl. magnitudes. Practical directions are given for prep. orthochromatic (300-600 mμ) and panchromatic (300-700 mμ) filters with aniline dyes. These filters are calibrated and their efficiencies ascertained by photographic density detns. throughout the entire spectral range of transmission. H. R. MOORE

Decay and regeneration of radio-luminescence. C. H. BIOL, G. D. KAMMER AND A. L. MILLER. *Nature* 115, 801-2(1925).—See C. A. 19, 2448. F. N. S.

Radiation from luminous flames. ALFRED SCHACK. *Z. tech. Physik* 6, 530-40 (1925).—The difference in temp. between the flame and the C particles in it is practically zero. The law of radiation absorption is applicable to this case. The absorption no.

of the C particles changes in the ultra-red and is approx. proportional to $\frac{1}{\lambda_{0.9}}$. Formulas are given for the calcn. of the radiation from the true and the black temps. J. H. P.

Life period of metastable s_3 and s_6 neon. H. B. DORGLO. *Naturwissenschaften* 13, 819; *Verslag Akad. Wetenschappen Amsterdam* 34, 779-86(1925).—For a certain period after interrupting the excitation of neon s_3 and s_6 atoms still exist and are able to absorb $1s_2-2p$ and $1s_6-2p$ lines from another emitting neon tube (cf. Meissner, C. A. 19, 1226). By 2 methods, one with rotating disk, the other with a c. of varying frequency (details to be published later), the life period of s_6 was found to be 1/240 sec., of s_3 1/2000 sec.

B. J. C. VAN DER HOEVEN

Remarks on the Zeeman effect and the structure of the ruthenium arc spectrum. L. A. SOMMER. *Naturwissenschaften* 13, 840-2(1925).—Contrary to conclusions recently given by Meggers and Laporte (C. A. 19, 260), S. found from Zeeman-effect observations on the quintet system that the ground term in the Ru arc spectrum is a reversed quintet F term. This makes the magnetic moment of the Ru atom under normal conditions equal to 7 Bohr magnetons.

B. J. C. VAN DER HOEVEN

The structure of the mercury green line $\lambda = 5460.74$ Å. U. and of the Balmer lines of hydrogen. J. C. MCLENNAN AND H. J. C. IRETON. *Trans. Roy. Soc. Can., Sec. III* (3)

19, 77-87(1925).—The Hg green line was examd. by an echelon grating made by Adam Hilger Co. The plates were 45 in number, 14.76 mm. thick and width of step was 0.1 mm. Light from a specially made Hg lamp was passed through a monochromatic filter designed for the Hg green line and the photographs were taken on panchromatic plates. Time of exposure was 3-9 min. The results showed the green line to be made up of 12 components and when a smaller echelon was crossed with the larger it was shown that 2 components had completely overlapped so that in reality there are 13 components. *Fine structure of Balmer Lines.*—The H α and H β lines were examd. with the echelon described above in the hope of obtaining a photographic record of the predicted third member of the Balmer lines. None was recorded. J. W. SHIPLEY

Analysis of the spectra of thallium by electrodeless discharge. W. C. MCQUARRIE. *Trans. Roy. Soc. Can., Sec. III (3) 19*, 57-62(1925); cf. *C. A.* 18, 1432.—An attempt was made to distinguish one order of spark spectrum from another in the electrodeless discharge spectrum of Tl and to establish the series relationships. A ring discharge through Tl vapor at 530° in a quartz tube was photographed through a Hilger const.-deviation spectrograph. The paper includes plates of the photographs and a table of the wave lengths, intensity and order of the lines observed. J. W. SHIPLEY

The peculiar form of discharge in argon. A. MOSKVIN. *Elektrichestvo (Russia)* No. 8, 464(1925).—The method employed for the purification of A for a special type of discharge was the one used for the rare gases, namely a discharge in the vapors of alkali metals (method of Salet, Zehnder and Mey, supplemented later by Gehehoff and Rottgardt). The app. consists of a cylindrical glass vessel with 2 electrodes. The upper electrode was a Pt plate, the lower one an alkali metal, heated to a temp. slightly above the m. p. The distance between the electrodes was 120 mm. At the time of discharge distinct luminous spheroid-shaped complexes appear near the surface of the alkali metal. They are slowly moving towards the other electrode but in most cases do not reach it, deviating from its course at an angle and disappear. Each sphere represents a luminous mass enveloped in a pale nebulous membrane. The diams of these spheres vary between 1 and 10 mm. The color is yellow when the lower electrode is Na. In most cases these spheres originate in the luminous membrane around the lower electrode; but sometimes between the electrodes and in exceptional cases at the top around the Pt electrode. The general movement, however, was from the Na towards the Pt and the speed varied within very wide limits. The greatest separation of such complexes is noticeable at times of applying the current and at change of potential. On contaminating the A with air (2%) the phenomenon is more pronounced in the sense of the number of spheres formed, but the size diminishes and correspondingly the time period of their existence. In most expts. impure A, or a mixt. of the rare gases, was used. The phenomenon seems to indicate the possibility of the existence of large complexes of activated mols. in an a. c. discharge. The more or less free and slow transport of the spheres at a discharge seems to point towards a low total charge. J. S. JOFFE

The under-water spark spectrum of a number of elements. MARY C. W. BUFFAM AND H. J. C. IRETON. *Trans. Roy. Soc. Can., Sec. III (3) 19*, 113-8(1925); cf. *C. A.* 16, 3037.—The object was to differentiate the spark from the arc spectra. By using an under-water oscillatory condenser discharge and a suitable condenser capacity in the circuit the arc lines were inverted on a dark continuous background while the spark spectra were not. The method was used for isolating the arc lines of Au, Ag, Cu, Co, Ni, Sb and Bi. The spectra were produced between metallic poles in a metal vessel through which distilled water circulated continuously. The light from the spark passed out through a quartz window and was focused on the slit by a cylindrical quartz lens. Hilger spectrographs were used for photographing the spectra. Wave-length tables and eight spectrum plates accompany the paper. J. W. SHIPLEY

Absorption spectra of various elements in the ultra-violet. J. C. MCLENNAN AND A. B. McLAY. *Trans. Roy. Soc. Can., Sec. III (3) 19*, 89-111(1925); cf. *C. A.* 19, 1096.—A continuation of the investigation of the absorption spectra of metals to obtain information regarding the outermost electrons of the neutral atom. This information was obtained by identifying the wave lengths constituting the arc spectrum of the element. Absorption by the non-luminous un-ionized vapor when the light from a spark or arc of the element under investigation was passed directly over the boiling metal was the method used. Making the absorption exposure longer than that of the comparison spectrum made it difficult to decide whether the reduction in intensity was due to selective absorption or to scattering. Absorption spectra of Au, Ag, Cu, Fe and Mn were obtained with the quartz spectrograph and of Au, Ag, Cu, Fe, Sb, Bi, As and Mn with the fluorite spectrograph. Tables of the absorbed wave lengths

together with those observed by others are given and two plates showing various sections from the spectra obtained accompany the paper. An addendum contains tables of absorbed wave lengths for Co, Ni, Cr and Fe obtained by using a carbon arc as source and the absorption lines reversed on the continuous background of the C arc spectrum.

J. W. SHIPLEY

Fluorescence radiation of nitrogen. O. OLDENBERG. *Proc. Nat. Acad. Sci.* **11**, 595-7(1925).—A condensed spark is produced in an atm. of N_2 at a pressure of a few tenths of a mm. of Hg. Stray discharges through the gas are prevented by suitable means. A ray of "ultra-Schumann" light from the spark produces fluorescence in the N_2 in its path. This fluorescence shows bands due to the neutral N mol. and to the N mol. ion, as proved by the work of Wien. In order to explain the high intensity of the bands due to the mol. ion relative to those from the neutral mol. it is assumed that the absorption of a quantum whose energy is greater than that required to remove an electron from the neutral mol. may in one act both ionize the neutral mol. and excite the ion. This corresponds to the simultaneous double electron jumps in the alk. earths which produce the primed spectral terms.

S. K. ALLISON

Fluorescence of colored vegetable materials. L. MEUNIER AND A. BONNET. *Compt. rend.* **181**, 465-7; *Chim. tech.* **14**, 486(1925), cf. *C. A.* **19**, 2758-3034.—Morin of yellowwood, quercetin of quercitron, rhamnetin of Persian berry and luteolin of yellowweed, which are similar in structure to fisetin, do not show fluorescence under Wood's light. The positions of the 4 (OII) groups in the mols. in the vegetable materials det. the occurrence, or not, of fluorescence. The fluorescent behavior of exts. of barberry, quebracho, curcuma, annatto, various red woods, saffron, alkanet and archil are compared with those of fisetin for the purpose of identifying the various vegetable coloring principles.

L. W. RIGGS

The infra-red spectra of certain elements. J. C. McLENNAN, H. G. SMITH AND C. S. PETERS. *Trans. Roy. Soc. Can., Sec. III* (3) **19**, 39-56(1925).—The spectra of N_2 , CO, Hg, Au and Te have been photographed in the region of 6000 to 9000 A. U. The photographs show no direct correspondence between the spectra of N_2 and CO in the infra-red region as was suggested by Nagaoka (*C. A.* **17**, 1587, 2388). Lines were found in the arc spectrum of Hg in the near infra-red region. A number of new lines have been photographed in the red and near infra-red regions. The paper includes wave-length tables and plates of the photographs.

J. W. SHIPLEY

A note on the vibration of the CO_2 group. P. A. TAYLOR. *Phil. Mag.* **50**, 1158-60 (1925); cf. Chapman and Ludlam (*C. A.* **20**, 11).

S. C. LIND

A class of one-valence-electron emitters of band spectra. R. S. MULLIKEN. *Phys. Rev.* **26**, 561-72(1925).—The similarity of the band spectra of the following mols. is discussed. BeF , BO , CO^+ , CN and N_2^+ , all are like Na at. in having $8 + 1$ electrons outside the nuclei and K electrons and their spectra resemble that of Na. MgF , AlO and SiN , contain an additional electron shell, but they are the probable emitters of similar band spectra. It is suggested that bands be grouped according to the no. of valence electrons of the emitters. Two causes of multiplicity in band spectra are suggested: (a) connected with the interaction of the emitting electron with the rest of the mol. and (b) attributed by Kratzer to the interaction of the angular momentum of the emitting and other electrons with that of the nuclei. Second negative N_2 bands of Duffendack may be due to neutral N mols. in each of which two electrons are initially excited. The familiar Al bands are probably due to AlO .

D. C. BARDWELL

Chemical action of light. HANNS JOHN. *Ber.* **58B**, 1563-5(1925).—Parallel expts were performed at Prague, Davos and in central Italy on the photochem. oxidation of toluene in presence of anthraquinone and air to benzoic acid in sunlight. The rates of oxidation in the 3 places were 0.0208, 0.0170 and 0.0397% per hour, resp.

F. C. KRACK

Photochemical potential changes. KARL SCHAUM AND WALTHER SCHLEUSSER. *Z. wiss. Phot.* **23**, 319-24(1925).—The relation $E = kT \log (\varphi/\varphi)(C_1/C_2)$ is found adequate to classify various photochem. and photovoltaic effects. E is the potential set up in the system under the influence of light; C_1 the concn. deduced from van't Hoff's isochore; C_2 the equil. concn. obtained from e. m. f. measurements. Changes in the value of C_1 control the potentials of both irreversible (catalytic) and reversible reactions. Thus the potentials of the catalytic change $2 Hg^{++} + (COO)_2^{--} \rightarrow$

$2 Hg^+ + 2 CO_2$ and the reversible reaction $Fe^{++} + Hg^+ \xrightleftharpoons[\text{dark}]{\text{light}} Fe^+ + Hg^{++}$ are

accounted for on this basis (cf. Baur, *C. A.* **13**, 282, 2627; Rideal and Williams, *C. A.* **19**, 1663). When the equil. concn. is altered by addn. of a foreign substance which

reacts in the light with both constituents (Becquerel effect), recovery of the system in the dark is very often impossible. Nevertheless, it is feasible by suitable regulation of conditions to suppress the Becquerel effect; *i. e.* to modify the characteristic "dark" potential. Persistent illumination of a soln. contg. 0.025 *M* $V_2(SO_4)_3$, 0.05 *M* $VOSO_4$, and 1.0 *M* H_2SO_4 , as well as equimol. mixts. of UO_2SO_4 and $U(SO_4)_2$, produces noticeable changes. Addn. of small amts. of H_2S occasions a more pronounced recovery of the dark potential, in spite of the irreversible sepn. of S. This recovery effect indeed is dependent on the presence in soln. of mixts. of V and U ions in different stages of valence, or a reducing agent such as H_2S , which favors this condition. H. R. MOORE

Mechanism of the photochemical reaction between hydrogen and chlorine. II. A. I. MARSHALL. *J. Phys. Chem.* 29, 1453-61 (1925); cf. *C. A.* 19, 3222. The yield of the photochem. reaction between H and Cl increases from about 20 to over 25,000 mols./quantum over the pressure range from 0.001 to 6.0 cm. Hg. At 5.9 cm. Hg the no. of mols. HCl/quantum does not change with a 20-fold increase of light intensity. A dynamic method was used, the pressures being measured over Hg after freezing out Cl and HCl. Some doubt exists regarding the partial pressures in the reacting system. The quantum calcs. are based on the empirical energy distribution in the Hg arc lamp as detd. by Coblenz, Long and Kahler (*C. A.* 13, 1284) and by Harrison and Forbes (*C. A.* 19, 1093). F. C. KRACEK

Infra-red absorption spectra of organic derivatives of NH_3 (BELL) 10. Photochemical and thermal decomposition of O_3 (GRIFFITH, MCKEOWN) 2. Ultra-violet radiations and antirachitic substances (DRUMMOND, WEBSTER) 11A.

Electric furnaces in foundry and metallurgical service. ERNST BLAU. *Chem.-Ztg.* 49, 673-4, 698-701 (1925).—In the *indirect arc* type of furnace, with from 0.2 to 1 ton capacity, 105-130 v. is needed, while for greater capacity 160-200 v. range is required. Six charges of steel or 10 charges of cast Fe can be melted in 24 hrs., the energy consumption being 800 kw. hr. per ton of steel and a little more than half this per ton of cast Fe. The life of the furnace roof is 3-4 weeks, of the hearth and side walls 300-400 charges. Larger furnaces (25 tons) are made with vertical electrodes, giving lower current consumption, 600-800 kw. hr., and a capacity of 5 charges in 8 hrs. The *Faul* furnace is similar to the *Hercoult* and uses graphite electrodes which can be renewed during the operation. This type gives 9 charges in 24 hrs. for the 5-ton size, and has lower heat losses with higher efficiency (75%). The energy required is 700-800 kw. hr. per ton in smaller types. In the *Humboldt* furnace, the electrodes move on rolls through the side walls and are pressed closer as the charge melts. The sizes run from 0.5 to 30 tons. The *induction* furnace has many advantages. It permits of closer regulation and more uniform heating. Small furnaces operate on 50-cycle a. c., but for larger sizes a lower frequency is necessary. This type of furnace is well adapted to deoxidation with ferro-alloys. Energy consumption is 100-150 kw. hr. per ton of steel. The installation cost is low, and a temp. control within 5° is possible. H. STORITZ

Converting an oil-fired furnace to electric heating. W. J. WALSH. *Elec. World*

86, 1110-1 (1925).—Resistors of 60 kw capacity were inserted in each of 2 chambers and $4\frac{1}{2}$ in. of insulation was placed around the outside of the old furnace chambers. From a 3 months' record the net factory costs were 90¢ less per ton of material treated when elec. heat was used. In addition 20% more material could be annealed in the same size chamber and a better product resulted with less dependence on the human element.

A. D. SPILLMAN

Types of electric heating appliances for industrial use. R. M. KEENEY. *Chem. Met. Eng.* **32**, 855-9 (1925).—Various designs of heaters and their application are discussed and illus. The importance of temp. control and careful consideration of conditions before purchasing equipment are stressed.

W. H. BOYNTON

The potential difference of carbon arcs with arbitrarily varying currents. R. 3. WALKER AND R. R. ROGERS. *Trans. Roy. Soc. Can., Sec. III* (3) **19**, 28 (1925); cf. *C. A.* **18**, 3148.—A d. c. varied and broken by a motor-driven mech. interrupter was used and the p. d. and current were recorded on a Siemens-Blondel oscillograph. Gaseous conductance after the arc was extinguished was observed. The production and extinguishing of the arc under varying conditions of voltage, current and time were recorded.

J. W. SHIPLEY

Some developments in the electrical industry during 1925. JOHN LISTON. *Gen. Elec. Rev.* **29**, 13-69 (1926).—Chapters on electric furnaces, arc welding, research, lighting, etc.

C. G. F.

Söderberg electrode shows low operating cost. M. SEM. *Chem. Met. Eng.* **32**, 865-6 (1925).—Savings in Söderberg electrode consumption are due partly to the absence of butts and partly to less air corrosion of the electrodes. The cost of manu. in the U. S. is 2.5-3.8¢ per lb. (454 g.), depending upon the size of the electrode, type of furnace and local conditions. A hollow type, in sizes up to 56 in. (140 cm.) diam., and with a 20 in. (50 cm.) hole is in regular operation.

W. H. BOYNTON

New process of calking furnace electrodes. ANON. *Elec. World* **86**, 1158 (1925).—A process has been developed of calking the space around furnace electrodes where they pass through the roof or shell of the furnace. The calking material consists of tar, pitch, etc., which forms a fluid seal around the electrodes at the higher temps.

A. D. S.

Artificial graphite electrodes: protection and improvement of electrodes used in the electrolysis of alkali chlorides. UMBERTO POMILIO. *Giorn. chim. ind. applicata* **7**, 63-7 (1295); *Chimie et industrie Special No.*, 286-316 (Sept., 1925).—A detailed description of a large no. of tests on the effects of impregnation of electrodes with paraffin, linseed oil, chlorinated linseed oil, naphthalene and chlorinated naphthalene on the life of the electrodes. Naphthalene and chlorinated naphthalene showed considerable protective action in the presence of SO_4^{--} and ClO_3^- , both of which exert a very destructive action; but with a pure electrolyte in which the anode is subjected to the much less destructive action of pure Cl^- the treatment is not of much advantage. Impregnation with linseed oil (both as such and chlorinated) is quite harmful, especially in the presence of SO_4^{--} and ClO_3^- , treated electrodes being destroyed much more rapidly than untreated ones; and this was confirmed in the course of com. operations. Irregularities and apparent anomalies in the results are attributed to inevitable variations in the graphite electrodes even from the same lot.

A. PAPINEAU-COUTURE

A new anode hanger for parting doré by the Moebius system. E. J. DAVID. *Eng. Mining J. Press* **120**, 368 (1925).—The old type of hanger was made of brass, Ni-plated with a half round spring to maintain tension on the jaws of the hanger. Solid Cu (NO_3)₂ would form at the contact point between the anode and jaws of the hanger, causing high resistance and excessive heating, with rapid corrosion of the hangers. The new hanger is made of pure Ag, cut from a sheet 0.05 in. thick, and is in 1 piece. No overheating from bad contacts occurs, some hangers having been in service ever since 1918.

H. S.

The effect of current and concentration on polarization in a lead cell. J. T. BURGERRANS AND H. R. HUGILL. *Trans. Roy. Soc. Can., Sec. III* (3) **19**, 26 (1925).—Two co axial Pb cylinders, one within the other, were used as electrodes and acids as electrolytes. During discharge polarization for dil. acids was entirely concn. polarization but with 30% H_2SO_4 it was due to exhaustion of active material at one or both electrodes. During charging no regular variation of polarization with concn. could be observed. The previous history of the cell influenced the rate of polarization. No polarization was observed at low current densities.

J. W. SHIPLEY

Glue for polishing [metals]. B. H. DIVINE. *Brass World* **21**, 320-2, 355-6 (1925).

C. G. F.

Preparation of benzaldehyde by electrolytic oxidation of toluene. I. G. KAWADA. *J. Pharm. Soc. Japan No.* **521**, 628-38 (1925).—The optimum conditions for prepn. of BzH by electrolytic oxidation of toluene with MnSO_4 in H_2SO_4 as electrolyte were in-

vestigated. The hourly production of BzH was detd. by iodometric titration. The results are given in 8 curves and 2 tables. The optimum conditions were: anolyte: 800 cc. MnSO_4 in H_2SO_4 (100 g. in 1000 cc. 55% I_2SO_4) and 250 cc. (217 g.) toluene; catholyte 55% H_2SO_4 ; electrodes, porous Pb plate 400 cm^2 ; current, 2 amp. (1 amp. per 300–400 cc. anolyte); e. m. f. 2.75–2.8 v.; temp. 53–55°; time 5 hrs. The use of a diaphragm and vigorous stirring are essential. S. T.

Electric gas purification. GRUHL. *Z. angew. Chem.* **38**, 565(1925).—G. reviews the various methods which have been used in the removal of solid or liquid particles from gases, waste or otherwise, and then describes elec. pptn. He discusses in detail the various methods used, results that can be obtained, the form of electrodes and pptn. chambers and roughly outlines the conditions of operation, such as e. m. f. required, current consumption, materials used in construction of electrodes and insulators and methods of removing pptd. particles. In addition to protection to the health of the community, valuable materials are recovered. G. describes the application of elec. pptn. to a few industries, with the results obtained. HOWARD STOERTZ

Electrical heating for vacuum impregnating apparatus. C. I. SMITH. *Chem. Met. Eng.* **32**, 818(1925).—The vacuum impregnating process affords an excellent means of obtaining a high insulating power. A resinous gum melting around 100° is used at a controlled temp. of between 160° and 170°. The connected load of the heating units described is 63 kw. for a 3000 gal. mixing tank, and two 1500 gal. treating tanks. Data on 7 months continuous operation are given. C. J. BROCKMAN

Impermeabilizing gas-absorbing substances (U. S. pat. 1,563,673) 18.

Electric battery. W. A. BURKHOLDER. U. S. 1,565,786, Dec. 15. Structural features.

Primary electric batteries. H. H. HIPWELL. U. S. 1,565,450, Dec. 15. Structural features.

Dry battery. D. ROSEN. U. S. 1,566,927, Dec. 22. Structural features.

Dry battery. C. P. DEIBEL. U. S. 1,562,945, Nov. 24. Structural features.

Dry batteries. H. DE OLANETA. U. S. 1,564,951, Dec. 8. Mech. features.

Galvanic battery of the copper oxide type. G. W. HEISE. U. S. 1,563,980, Dec. 1. In cells with Cu oxide depolarizer and caustic electrolyte, a cellulosic material is used to fix dissolved Cu.

Electrolyte for galvanic batteries. R. PORSCKE. U. S. 1,562,517, Nov. 24. A battery is formed with an artificial Mn-O compd. as depolarizer and with an electrolyte comprising a soln. of CaCl_2 , MgCl_2 or other alk. earth metal chloride free from NH_4 salts and also free from dissolved substances of a highly oxidizing character and initially contg. a small quantity of a Hg salt.

Protecting battery terminals from corrosion. G. K. FRANKLIN. U. S. 1,565,994, Dec. 15. Two mixts. are prepd., one consisting of NaHCO_3 5 and graphite 2 5 parts, the other of "ammonia" 2, "carbolic acid" 1, lubricating oil 1 and alc. 1 part. The 2 mixts. are united before use.

Device for releasing oil on immersion in the electrolyte of batteries. M. L. MARTUS, E. H. BECKER and H. B. SCHOENMEHL. U. S. 1,532,252, April 7, 1925.

Storage battery. R. B. OWEN. U. S. 1,565,193, Dec. 8. Structural features.

Storage battery. J. G. JACKSON. U. S. 1,562,887, Nov. 24. Structural features.

Storage battery. E. H. WILLIAMS. U. S. 1,564,163, Dec. 1. Structural features.

Storage battery. S. C. FORD and W. A. SHULER. U. S. 1,564,173, Dec. 1. Structural features.

Storage battery and hydrometer attachment. E. C. CLIFFORD. U. S. 1,564,530, Dec. 8. Structural features.

Storage battery grids. H. W. LORMOR. U. S. 1,566,280, Dec. 22. Structural features.

Storage battery plates. J. M. BURNETT. U. S. 1,564,524 Dec. 8. Structural features.

Storage battery separators. R. N. CHAMBERLAIN. U. S. 1,566,826, Dec. 22. Separators formed from wood are treated with acid-resistant material such as paraffin, rubber or linseed oil and subjected to the action of an alkali, e. g., a 1–2% NaOH or Na_2CO_3 soln. at a temp. of about the b. p. This treatment serves to improve the cond. of the separators.

Utilizing old plate material from lead storage batteries. J. O. LUTHY. U. S. 1,563,506, Dec. 1. See Brit. 230,058 (C. A. 19, 3224).

Preventing corrosion and sulfating of storage batteries. F. D. BASS. U. S. 1,562,489, Nov. 24. A compn. for preventing corrosion of battery terminals is formed from $(\text{NH}_4)_2\text{CO}_3$, NaHCO_3 , creosote, urease, oil and acid-proof paint.

Apparatus for filling storage battery cells with electrolyte. A. R. WILLARD. U. S. 1,565,347, Dec. 15

Container for storage battery electrolytes or other corrosive liquids. K. E. EDGEWORTH. U. S. 1,564,766, Dec. 8. A soft flexible rubber bag is secured within an outer casing of ebonite or similar materials.

Electrolytic cell adapted for electrolysis of water to produce hydrogen and oxygen. A. E. KNOWLES. U. S. 1,566,543, Dec. 22. The cell is constructed automatically to control the liquid level and to wash the gas evolved.

Electrolytic cell adapted for electrolysis of sodium chloride solutions. M. W. COWLES. U. S. 1,564,406, Dec. 8.

Electrolytic diaphragm cells adapted for making caustic soda. W. E. MORTRUDE, JR. U. S. 1,566,804, Dec. 22.

Electrode for primary batteries. F. J. WOLFE. U. S. 1,564,741, Dec. 8. Structural features.

Electrode for use in making sulfuric acid. F. VORLANDER and H. WEBER. U. S. 1,565,691, Dec. 15. Pptg. electrodes for use in H_2SO_4 by the contact process are formed with frames made of Cu and wood or other material which does not react with H_2SO_4 to evolve H. These frames are coated with Pb.

Silicic acid. N. L. COLLINS. U. S. 1,562,940, Nov. 24. An aq. soln of water glass is electrolyzed between a Hg cathode and an anode which is maintained in continuous agitation and which may be formed of Pb.

Electrolysis of alkali chlorides. H. KLOPSTOCK. U. S. 1,565,943, Dec. 15. In electrolysis of KCl or other alkali chlorides by the so-called quicksilver process, involving a transfer of the Hg from the amalgam decomn. cell to the amalgam formation cell by a fluid propelling device, the Hg is protected throughout its transfer by an air excluding fluid such as H_2O or an inert gas.

Copper carbonate. H. HOWARD. U. S. 1,565,367, Dec. 15. A soln. contg. NaHCO_3 or other material which will supply CO_2 and NaClO_4 or other electrolyte is electrolyzed in the presence of a Cu anode, carbonated during the electrolysis, and CuCO_3 formed is removed from the soln.

Electrolytic copper. F. L. ANTISELL. U. S. 1,566,265, Dec. 22. Electrolysis of Cu solns. is carried out in cycles during a definite fraction of each of which the current is impressed. This mode of operation serves to produce dense Cu, free from twinned crystals and amorphous deposits of Cu or H.

Electrodeposition of cadmium. C. M. HOFF. U. S. 1,564,413, Dec. 8. An electrolyte for Cd deposition is formed from reaction products of Cd and Zn, aq. NH_3 soln. and alkali metal cyanide. U. S. 1,564,414 specifies the use of an electrolyte formed with $\text{Cd}(\text{OH})_2$, $(\text{NH}_4)_2\text{SO}_4$, alkali metal hydroxide and cyanide and "gulac."

Electrolytic production of aluminium. J. B. RAILSBACK. U. S. 1,566,694, Dec. 22. A bath for Al production comprises compds. of Al such as Al_2O_3 and a metal, e. g., Li, Be, Mg, Ca, Sr or Ba, the oxide of which is not reducible by Al and which is liberated from an added halide, sulfide, selenide or telluride.

Precipitating gold from solutions. W. H. BATES. U. S. 1,563,957, Dec. 1. A cathode of Hg with an extended surface is used and placed in close relation to an anode with a large active area.

Recovering lighter values from mineral-bearing slimes. C. A. McCOURT. U. S. 1,566,755, Dec. 22. In treating slimes such as those of Au and Ag ores, a continuous flow of an amalgamating soln. is passed through an electrolytic cell and streams of the soln. flowing from the cell are diverted onto the slimes at sep. points during the course of flow travel for the recovery of the lighter values. The amalgamated values are sep'd. from the soln. formed and the spent liquor is returned to the electrolytic cell.

Pickling iron or steel. C. P. MADSEN. U. S. 1,562,710, Nov. 24. Fe, steel or similar surfaces are prep'd. for treatment with Zn or other adherent coating metals by making the article to be coated an anode in a bath contg. H_2SO_4 of more than 86% strength maintained at a temp. above normal (preferably about 55°).

Steel and iron alloys. B. D. SAKLATWALLA. U. S. 1,564,139, Dec. 1. A molten bath of steel or Fe is formed with a molten supernatant electrolyte bath contg. a Cr or U compd. or other unreduced compd. of an alloying metal and the latter is electrically reduced.

Calcium copper alloy. W. G. HARVEY. U. S. 1,563,187, Nov. 24. A molten Ca salt such as CaCl_2 is electrolyzed in the presence of a solid Cu cathode until sufficient

Ca has been taken up by the cathode for it to become molten at the temp. of the molten salt

Metallic coatings on porous nonmetallic materials. K. RIPPER. U. S. 1,563,793, Dec. 1. Wood or other material to be coated is rendered conductive by the use of a cond substance, *e. g.*, graphite, in such a high degree of dispersion that the particles are smaller than the pores of the material treated and the latter is then electroplated.

Coating flexible metal articles with nickel or similar coating metals. C. P. MADSEN. U. S. 1,562,711, Nov. 24. A workable electrodeposit of Ni or similar metal is formed on sheet steel, etc.

Preparing metal surfaces to receive adherent metal coatings. A. Z. PEDERSEN. U. S. 1,564,710, Dec. 8. In prepg. metal surfaces for coating, *e. g.*, prepg. Fe or steel surfaces for coating with Ni, the metal is made an anode in a bath contg. H_2SO_4 of over 75% strength.

Eliminating iron from solutions obtained from leucitic rocks. U. POMILIO and F. GIORDANI. U. S. 1,559,179, Oct. 27. SiO_2 is removed from a soln. such as is obtained by treating leucitic rocks with HCl and the silica-freed soln. is then electrolyzed to remove Fe and further electrolyzed in diaphragm cells to obtain Fe-free products.

Electrodeposition of duplicates of sound records, etc. A. J. CAWLEY. U. S. 1,557,980, Oct. 20. Mech. and elec. features.

Electric resistance furnace. A. D. KEENE. U. S. 1,565,466, Dec. 15.

Electric resistance furnace adapted for heating water. A. GRAUEL. U. S. 1,566,855, Dec. 22.

• **Electric crucible furnace.** M. UNGER. U. S. 1,564,800, Dec. 8.

Electric arc furnace adapted for refining metals. G. EVREYNOFF. U. S. 1,562,825, Nov. 24.

Gas reactions in electric furnaces. M. J. BROWN. U. S. 1,562,684, Nov. 24. In effecting HCN production from H, N and C or similar gas reactions in an elec. furnace employing a resistor of comminuted material such as granular graphite between the electrodes, the resistor material is supplied at such a rate with the reacting gas as to control the elec. resistance

Furnace electrodes. H. A. LAVENE. U. S. 1,566,409, Dec. 22. Porous C electrodes adapted for use in elec. furnaces are treated with 2 sol. compds. such as $CaCl_2$ and Na silicate which form a refractory product in the pores of the electrodes

Automatic current and temperature control for electric furnaces. E. V. SCHAAAL. U. S. 1,563,441, Dec. 1.

Electrically heated core oven. F. A. COLEMAN. U. S. 1,564,945, Dec. 8.

Electroplating. J. G. SWAIN. U. S. 1,565,683, Dec. 15. Articles such as metal automobile rims are subjected to an electrolyte charged simultaneously from anodes of Zn and Hg.

Electroplating iron surfaces. R. J. SHOEMAKER. U. S. 1,566,984, Dec. 22. Fe or steel surfaces to be plated are first covered with an adherent film of Hg and an amalgamated metal such as Cu and the surface is then electroplated with Pb or other metal.

Electroplating with nickel. W. R. KING. U. S. 1,564,581, Dec. 8. Fe or other corroddible metal is coated with a Ni-Zn alloy and then with an outer coating of Ni.

Electroplating apparatus with a rotary plating barrel. F. G. PURINTON. U. S. 1,563,041, Nov. 24.

Electroplated stereotype plate or nickel-plated printing plate. C. N. SMITH. U. S. 1,565,216, Dec. 8. The printing side of a molded stereotype plate to be plated is treated with an aq. soln. contg. $HgCl_2$ to remove foreign substances from the surface of the plate and produce a lusterless surface which is then electroplated.

Preparation of tungsten powder. NAAMLIOOZE VENNOOTSCHAP PHILIPS' Gloeilampenfabrieken. Dutch 13,749, Oct. 15, 1925. WO_3 is dissolved in 1 : 5 NH_4OH , a soln. contg. 5-20% as much K_2CO_3 as the wt. of WO_3 is added, filtered and the soln. evapd on the water bath. From the dried mixed crystals ($K NH_4$ paratungstates) WO_3 is formed by heating in a quartz crucible; it contains some nonvolatile alkali. The oxide, reduced in H_2 gives W powder, well suited for prepn. of W wire. Heating of the WO_3 before reduction in a Battersea crucible (1200°, 3½ hours) makes it take up some SiO_2 and Al_2O_3 , which also improves the qualities.

Composite metallic filaments. G. R. FONDA. U. S. 1,565,724, Dec. 15. A wire of W or similar refractory metal is coated with another alloyable metal such as Fe or Zr and heated sufficiently to cause alloying and diffusion of the coating metal throughout the wire.

Incandescent lamp. G. R. FONDA. U. S. 1,566,848, Dec. 22. C_2H_2 , CH_4 , C_3H_8

or other C-contg. material is used in lamp bulbs for chem. reaction with gases such as H_2O vapor in the bulb to improve its operating properties.

Introducing potassium or similar vapors into electric lamps. A. M. HAGEMAN. U. S. 1,565,564, Dec. 15. An amalgam of relatively high m. p. is prepd. from an alkali metal such as K and introduced into the lamp in contact with one of its metallic parts. Subsequently the amalgam is elec. heated to volatilize the alkali metal.

Cores for cathodes of vacuum tubes. H. T. REEVE. U. S. 1,565,200, Dec. 8. A mixt. of metals including powd. Pt and Ni is pressed into a coherent ingot, heated to a sintering temp. under non-oxidizing conditions, and cold worked into filaments (with annealing at high temp. at intervals). The initial stages of the cooling are effected also under non-oxidizing conditions.

Converting electrical energy into radiant energy during combustion. G. T. SOUTHWATE. U. S. reissue 16,149, Aug. 25. Mobile combustible and oxidizing substances such as combustible gas and air are forced through a nozzle contg. a filling of coke or other porous, elec. conductive material resistant to heat, to maintain combustion and an e. m. f. is impressed upon the filling material sufficient to cause an elec. arc conduction from it into and along the combustion flame, which augments the heating effect, *e. g.*, in smelting.

Electrical commutator brush. R. L. HENRY. U. S. 1,556,990, Oct. 13. A mixt. such as graphite and a phenol-formaldehyde condensation product is solidified by heat and subjected to pressure in such a manner as to give the product different desired resistance characteristics in different directions.

Material for fuses. F. A. FELDKAMP. U. S. 1,564,335, Dec. 8. A material for elec. fuses comprises a mass of metallic particles, *e. g.*, Cu, bonded by solder or other metal of low m. p.

5—PHOTOGRAPHY

C. E. K. MEES

Solarization of the photographic plate. J. M. EDER. *Z. physik. Chem.* 117, 293-8(1925).—The statement of Arens that a bromosilver gelatin plate impregnated with nitrite gives so intensive a direct photochemical blackening that it makes solarization impossible does not correspond with exptl. results in the ordinary solarization region, and the conclusions drawn from this statement are, therefore, unfounded.

E. P. WIGHTMAN

Emulsion films (HOLMES) 2.

Reversal of photographic images. J. G. CAPSTAFF. U. S. 1,564,753, Dec. 8. A light-sensitive element contg. a Ag image and a complementary image of sensitive Ag salts is submitted to a bath which may contain $K_3FeC_6N_6$ and KBr in H_2O soln., to convert the Ag image into a different insensitive image without rendering the sensitive salts insensitive. The element is then exposed to light and developed to produce a Ag image from the light-affected Ag salts. Cf. C. A. 19, 3438.

Multicolored screens for use in photography. J. H. CHRISTENSEN. U. S. 1,564,202, Dec. 8. Basic dyes and mordants such as tannic, molybdic, tungstic or phosphotungstic acids are dissolved in a suitable solvent, *e. g.*, an alc. or NH_3 soln. and the solns. are emulsified in sep. portions of rubber and gum dammar soln. or other substantially neutral viscous emulsifying medium. The major part of the emulsifying medium is removed by dilg. with a solvent such as C_6H_6 , gasoline or CCl_4 , and decanting. A mixt. of differently colored particles is caused to adhere to a neutral carrier, *e. g.*, glass, celluloid or hardened gelatin, and dried after removal of surplus particles.

Producing photographic copies by use of phosphorescent substances. J. H. CHRISTENSEN. U. S. 1,565,256, Dec. 15.

Fluoroscopic screen. I. S. HIRSCH. U. S. 1,563,856, Dec. 1. Heat is applied to the surface of a fluorescent screen (which may be formed of ZnS contg. a trace of Cu) in order to obtain persistence of images on the screen.

Daylight developing of photographic plates and films. G. D. RODRIGUEZ. U. S. 1,563,228, Nov. 24. Mech. features.

Printing color cinematographic films. P. D. BREWSTER. U. S. 1,563,959, Dec. 1. Mech. features.

Sensitizing "kinofilms" for positive copies. A. WEINGARTEN. U. S. 1,564,161,

Dec. 1. In sensitizing "kinofilms," the colloid is treated with a soln. of $K_2Cr_2O_7$, $K_4FeC_6N_6$ and KBr .

Blue prints with dark lines and white fields. R. C. BROWN. U. S. 1,566,305, Dec. 22. An impression or transfer sheet provided upon its under side with an opaque coating is imposed upon a plain sheet and a drawing is superposed. The drawing is traced to produce upon the plain sheet a replica of the drawing for checking purposes and convert the impression sheet into a negative by the transfer of the coating to the plain sheet in the tracing operation. The coating is fixed upon the negative by applying a preservative such as white shellac and copies are printed upon sensitized paper by passing light rays through the open lines of the drawing.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Contributions to the knowledge of ruthenium. VIII. The isomeric chlorides.

JAS. I. HOWE AND L. P. HAYNES. *J. Am. Chem. Soc.* **47**, 2020-5(1925).—The chlorides of Ru exist in 2 series: α -salts, $MRuCl_3$ and $MRuCl_3 \cdot H_2O$, solns. of which are deep brownish red, yielding 2 Cl atoms to H, but which do not take up Cl; β -salts, which are the "aquo" salts of the α , probably isomeric monohydrates. Their solns. are rose-red; H_2O splits off 1 Cl atom and Cl converts them to the hexachloride. The dehydrated β -salts are identical with those formed from the hexa- by the loss of 1 Cl atom. They are isomeric with the α -salts, but not identical. Their solns. give, on standing, the β -salt. The bromo salts thus far examd. are similar to the chloro salts. M. O. L.

The chlorides and oxides of rhodium. LOTHAR WÖHLER AND W. MÜLLER. *Z. anorg. allgem. Chem.* **149**, 125-38(1925).—Only trivalent compds. of Rh with Cl were definitely known hitherto. The authors found the temp. ranges of formation of $RhCl_3$ at 300-948°. If the temp. rises to 968° a mixt. of $RhCl_2$ and $RhCl$ results. The existence of these 2 new chlorides was confirmed by their pressure curves. Like $RhCl_3$ they are insol. in water and acids. Attempts to prep. a tetrachloride were unsuccessful. The authors proved also that besides Rh_2O_3 , RhO and Rh_2O exist. They are produced when Rh_2O_3 is heated above 1113° or 1121°, resp. Like the chlorides they may be sepd. by flotation with C_6H_6 or CCl_4 . They are insol. in acids and aqua regia and are sensitive to H, a reduction taking place accompanied by a spontaneous rise of temp. Rh metal shows no change at 1150°, thus proving to be like Pd the least volatile metal of the Pt group. ÉMIL KLARMANN

The black oxides of praseodymium. WILHELM PRANDTL AND KARL HUTNER. *Z. anorg. allgem. Chem.* **149**, 235-62(1925).—There are contrasting statements in the literature on the no. and the properties of oxides of Pr. When the nitrate, carbonate or oxalate of Pr is ignited in air, a dark brown or black oxide forms which has the formula Pr_6O_{11} according to the analysis carried out by the authors in 3 different ways. Since the ppt. of Pr oxalate obtained from the sulfate retains considerable amts. of the sulfate even after repeated repptn. from dil. HNO_3 , the formation of H_2S may be observed when the reduction is carried out in a current of H gas. This fact is likely to lead to incorrect results of analysis. Some of the phys. and chem. properties of Pr_6O_{11} are given. Thus O_3 forms in small quantities when this oxide is dissolved in acids. The authors state that older reports on the formation of higher oxides cannot be correct. Thus no PrO_2 forms when $Pr(NO_3)_3$ is heated with KNO_3 . It is, however, possible to obtain a compd. of the formula PrO_2 or Pr_nO_{2n} , resp., by heating Pr_2O_3 in a current of O at 300° for 2 days or by melting Pr_6O_{11} with $NaClO_3$ at 270-80° for 15-20 min. $NaBrO_3$ does not change the Pr_6O_{11} . On heating with dil. $AcOH$ a red-brown powder results; its compn. corresponds to the formula $Pr_4O_8 \cdot H_2O$. This suggests that Pr_6O_{11} is a salt-like compd. (praseodymium praseodymate) similar to Pb_3O_4 which consists of PbO and PbO_2 . PrO_2 dissociates above 350°, forming Pr_6O_{11} and O. The authors also investigated the action of other oxides, e. g., La_2O_3 , Bi_2O_3 , Fe_2O_3 , Ce_2O_3 , Nd_2O_3 , on the course of oxidation of Pr_2O_3 . Conclusion: Tervalent Pr resembles tervalent Ce. Pr_2O_3 has the same formula and crystal structure as Ce_2O_3 ; it is, however, unable to form salts with acids analogous to the ceric salts. Some tentative structural formulas of the 2 black oxides are suggested. ÉMIL KLARMANN

Higher oxides of silver. II. Silver peroxide. FR. JIRSA. *Chem. Listy* **19**, 300-6 (1925); cf. C. A. **19**, 3201.—Dissolution of Ag_2O_2 in HNO_3 yields brown solns. of high oxidizing power. The Ag_2O_2 is partly decompd., yielding Ag^+ and active O and partly goes into soln. in the acid. The higher the HNO_3 concn. and lower the temp. the more Ag_2O_2 goes into soln. as such. It can be repptd. by dilg. the acid soln. with H_2O . Salts

of Ag^{++} have been prep'd. by others. The dissociation pressure of Ag_2O_2 is extremely high. Calcn. by means of the approx. Nernst formula based on the heats of reaction det'd. by J. (C. A. 19, 3201) yields pressures of the order of 10^8 and 10^9 atm. at 25° for the reactions (1) $\text{Ag}_2\text{O}_2 = \text{Ag}_2\text{O} + \frac{1}{2} \text{O}_2 + 1000$ cal and (2) $\text{Ag}_2\text{O}_2 = 2\text{Ag} + \text{O}_2 - 5140$ cal., resp. Decompn. takes place according to (1). E. m. f. measurements indicate that solid solns. of Ag_2O and Ag_2O_2 are formed. Very little autocatalysis takes place. The comp'd. is thermodynamically unstable, but practically, on account of some passivity phenomena, its decompn. is negligible at room temp. Some decompn. takes place in the dry prep'n. at 100° ; boiling water acts on the comp'd. until a sat'd soln. of AgOH is formed. The washed residue has the comp'n. corresponding to Ag_2O_2 . Bibliography. F. C. KRACEK.

Different states of the oxide of beryllium. H. COPAUX AND C. MATIGNON. *Compt. rend.* 181, 550-2; *Bull. soc. chim.* 37, 1359-65 (1925).—When basic Be carbonate is calcined, there is a small progressive loss of wt. as the temp. increases from 700 to 1100° . This loss of wt. is due either to loss of occluded H_2O or to polymerization with loss of H_2O and is accompanied by an increase of density. The oxide which has been calcined at 1100° dissolves in HF only half as rapidly as that which has been calcined at 800° and has a larger heat of soln. R. J. HAVIGHURST.

Iron arsenides. E. VIGOUROUX. *Chimie et industrie Special No.*, 283 (Sept., 1925).—The e. m. f. diagram of Fe-As alloys contg. 6-56% As shows the presence of Fe_2As and of Fe_3As . A. PAPINEAU-COUTURE.

Electromotive force diagrams of manganese arsenides. G. ARRIVAUT. *Chimie et industrie Special No.*, 284-5 (Sept., 1925).—The e. m. f. diagram of Mn-As alloys contg. 6-53% As shows the presence of Mn_2As and of Mn_3As . It was not found possible to prep. an alloy contg. 57% As (corresponding to MnAs), as the mixt. decomposed on fusing. A. PAPINEAU-COUTURE.

Complex salts of stannous iodide with the iodides of rubidium and of cesium. V. AUGER AND T. KARANTASSIS. *Compt. rend.* 181, 665-6 (1925).—Addn. of SnI_2 to warm aq. RbI contg. HI gives a liquid which rapidly turns brown in the air and deposits SnI_4 . But with Sn present and with air absent the pale yellow liquid yields products contg. different proportions of Sn and Rb. With excess RbI , the comp'd. SnRbI_3 is formed, yellow needles. Satn. of hot RbI soln. with SnI_2 gives the comp'd. Sn_2RbI_6 , yellow-orange microscopic cubes. By following the same 2 methods with CsI , the comp'd. SnCsI_3 , yellow needles, and the comp'd. Sn_2RbI_6 , yellow-orange cubes, are obtained. These Rb and Cs compds., relatively stable when dry, oxidize in the air rapidly, blackening and forming in part SnRbI_6 and SnCsI_6 . They do not, therefore, correspond to the reaction products of stannous halides with K and NH_4 salts. C. C. D.

Additive compounds of hydrogen chloride and the sulfates of heavy metals. FRITZ EPHRAIM. *Ber.* 58B, 2262-7 (1925).—Unlike water and NH_3 the H halides do not usually show a tendency to form additive compds. Expts. aiming at the prep'n. of additive compds. of the chlorides of heavy metals and HCl were unsuccessful. Additive compds. of the corresponding sulfates and HCl, however, were obtained, when the dry salts were treated with dry HCl at temps. peculiar to each salt. Two mols. of HCl are taken up by 1 mol. of the sulfate (except ZnSO_4). The resulting comp'd. is represented by the formula $\text{Me} \left[\begin{smallmatrix} \text{SO}_4 \\ \text{Cl}_2 \end{smallmatrix} \right] \text{H}_2$, or $\text{Me} \left[\begin{smallmatrix} \text{SO}_4 \\ (\text{HCl})_2 \end{smallmatrix} \right]$. The products are absolutely dry

and possess characteristic dissociation temps. lying close to the decompn. temps. of their chlorides, when treated with concd. H_2SO_4 . It is possible that in the reaction $\text{MeCl}_2 + \text{H}_2\text{SO}_4 \longrightarrow \text{MeSO}_4 + 2\text{HCl}$ first an additive comp'd. $\text{MeSO}_4 \cdot 2\text{HCl}$ forms which subsequently decomposes. Thus this reaction would not have to be regarded as an ion reaction. This surmise is supported by the fact that a great tendency to form such additive compds. is shown by the sulfates of those metals which form slightly dissociated chlorides. $\text{HgSO}_4 \cdot 2\text{HCl}$ shows the greatest resistance against heat. On the other hand no HCl is developed from HgCl_2 even by boiling H_2SO_4 . While CdSO_4 , CuSO_4 and Ag_2SO_4 take up 2 mols. of HCl at room temp., PbSO_4 and ZnSO_4 must be cooled down (the latter takes only 1 mol. of HCl). HgSO_4 absorbs very little HCl at room temp. whereas the absorption becomes very violent at 125° . On heating all these additive compds. give off HCl at a characteristic temp., but 0.5 mol. is retained and may be driven off at a higher temp. This suggests the possibility of existence of another kind of additive compds. EMIL KLARMANN.

Pseudohalogens. II. 1. The fulminic acid residue. 2. The equilibrium between iodine, selenocyanogen and the corresponding silver salts. 3. Polypseudohalides. LOTHAR BIRKENBACH AND KARL KELLERMANN. *Ber.* 58B, 2377-86 (1925); cf. C. A. 19, 1996.—The position of the fulminic acid residue in the electromotive series of pseudo-

halogens has been ascertained by comparison of the cyanate and fulminate of Hg. The electroaffinities of halogens and pseudohalogens are represented by the following series: $\text{TeCN} \cdot \text{SeCN} \cdot \text{I} \cdot \text{SCN} \cdot \text{CN} \cdot \text{Br} \cdot \text{N}_3 \cdot \text{Cl} \cdot \text{OCN} \cdot \text{CNO} \cdot \text{F}$. Since particularly the higher halogens show a tendency to formation of polyhalides of alkali metals, when the normal halides are evapd. at low temps. with the calcd. amt. of dissolved halogen, the same behavior was studied with pseudohalogens. It was established electrometrically that compds. of the type of KI_3 , namely $\text{K}(\text{SeCN})_2$, $\text{K}(\text{SeCN})_2\text{I}$ and $\text{K}(\text{SeCN})_3$, exist in non-aq. solns. The titration was carried out by gradual addition of an ethereal soln. of the pseudohalogen to the alc. soln. of a known amt. of the pseudohalide of K. A Ag wire, superficially covered with AgI, and a soln. of 0.1 N KI in abs. EtOH satd. with AgI (solid AgI was present) were used as a normal electrode. This system is generally recommended as a normal electrode for alc. and ethereal solns. Polypseudohalides of Cs are obtained by evapn. of titrated solns. of the respective Cs halide with an ethereal soln. of the pseudohalogen. Thus $\text{Cs}(\text{SeCN})_3$ was isolated as a red-brown salt, sol. in EtOH, stable in air; it is decomposed by water. These compds. are interesting also from the standpoint of the valency problem, since it may be shown that the outer electron ring of such a complex probably contains 7 electrons in conformity with similar conditions in halogens. The complex formed would give 15 electrons (figured from its individual constituents) 8 of which produce one satd. sphere; the remaining 7 electrons form the outer sphere to which is due the particular chem. nature of the complex, i. e., its relation to the halogens.

EMIL KLARMANN

The reversible system $\text{PbI}_2 + \text{ZnSO}_4 \rightleftharpoons \text{ZnI}_2 + \text{PbSO}_4$. C. G. STOFFELLA. *Boll. chim. farm.* **64**, 481-8(1925).—The reaction is complete from left to right only in dil. equimol. solns. at 100° in spite of its being exothermic. This is due to the considerable increase in the soly. of PbI_2 with the temp. The reaction is incomplete in a satd. soln. at 100° or in a highly dil. soln. at 15° .

MARY JACOBSEN

Neodymium and thallous sulfates. F. ZAMBONINI and V. CAGLIOTI. *Atti. accad. Lincei* [6] **2**, 153-8(1925).—In extending recent work on the system $\text{La}_2(\text{SO}_4)_3 \cdot \text{Tl}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ (Z. and Carobbi, *C. A.* **19**, 2920) the system $\text{Nd}_2(\text{SO}_4)_3 \cdot \text{Tl}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ was also studied at 25° . The same methods of analysis were again used. The $\text{Nd}_2(\text{SO}_4)_3$ used was nearly pure and was the same as was used in prepg. the Nd-K double sulfates (*C. A.* **19**, 2309). Three compds. were found in the solid phase: $\text{Nd}_2(\text{SO}_4)_3 \cdot 4.5\text{Tl}_2\text{SO}_4$ (I), $\text{Nd}_2(\text{SO}_4)_3 \cdot \text{Tl}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$ (II), $\text{Nd}_2(\text{SO}_4)_3 \cdot \text{Tl}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$ (III). The compd. corresponding to I was also found with La having $2\text{H}_2\text{O}$. The Nd compd. corresponding to $\text{La}_2(\text{SO}_4)_3 \cdot 3\text{Tl}_2\text{SO}_4$ was not formed in this system. The field of existence of I is less extensive than that for the La compd. since it competes for existence with II. Neither of the double sulfates described by Zschiesche (*J. prakt. Chem.* **107**, 100(1869)) were found under these conditions. II is obtained as violet crystals in equil. at 25° with solns. contg. 3.8% $\text{Nd}_2(\text{SO}_4)_3$ and 0.26-0.27% Tl_2SO_4 . It is nearly impossible to obtain it entirely pure, i. e., free from $\text{Nd}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$ and III. III is obtained as violet crystals in equil. with solns. containing 3.78-0.30% $\text{Nd}_2(\text{SO}_4)_3$ and 0.28-3.00% Tl_2SO_4 and has a wide field of existence. III is isomorphous with double sulfates $\text{NH}_4\text{X}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ (X = La, Ce, Di) and its crystallographic description is fully given. III loses $6\text{H}_2\text{O}$ at 130° and the rest is eliminated at 200° . I is stable in solns. containing 0.26-0.19% $\text{Nd}_2(\text{SO}_4)_3$ and 3.85-4.70% Tl_2SO_4 and is obtained as a bright violet-red powder.

E. J. WITZEMANN

The double sulfates of the rare earth metals and of the alkali metals. III. Double sulfates of lanthanum and sodium. F. ZAMBONINI and G. CAROBBI. *Atti. accad. Lincei* [6] **2**, 300-2(1925).—In continuing previous work (*C. A.* **19**, 2920) on the double sulfates of the alkaline and rare earth metals the system $\text{La}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ was studied at 25° by the methods previously describd. The solid phase was $\text{La}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ and no other was observed. This compd. is stable in contact with solns. containing 0.13-16.28% Na_2SO_4 and 0-0.19% $\text{La}_2(\text{SO}_4)_3$. At 150° this double salt does not lose its H_2O of crystn.

E. J. WITZEMANN

A study of the thermal decomposition of sulfates. Mlle. GERMAINE MARCHAL. *J. chim. phys.* **22**, 413-31, 493-517(1925); cf. *C. A.* **19**, 3201.—In general, sulfates can undergo thermal decompn. according to one of the following schemes: (a) simple dissoc. into metallic oxide and SO_3 , e. g., $\text{MgSO}_4 = \text{MgO} + \text{SO}_3$; (b) dissoc. accompanied by formation of a more stable oxide than that involved in the formation of the original salt, e. g., $3\text{MnSO}_4 = \text{Mn}_3\text{O}_4 + 2\text{SO}_3 + \text{SO}_2$; (c) dissoc. accompanied by dissoc. of the basic oxide, e. g., $2\text{Ag}_2\text{SO}_4 = 4\text{Ag} + 2\text{SO}_3 + \text{O}_2$. At even moderate temps. all of the above reactions are followed by (d) $2\text{SO}_3 = 2\text{SO}_2 + \text{O}_2$. Bodenstein and Pohl investigated the latter reaction (*Z. Elektrochem.* **11**, 373(1905)), giving as their result $\log K_c = -10,373/T - 2.222 \log T + 14.585$. The stoichiometric relations in

volved in the decompn. of the different types of sulfates and a measurement of the total pressures at a series of temps. together with the above equation for K , furnish all the necessary data for the calcul. of the partial pressures of SO_3 , SO_2 , and O_2 in the thermal decompn. of these salts. M. measured the pressure over Hg, which withstood the action of the gases reasonably well. The sulfates were heated in porcelain boats placed inside a porcelain reaction tube, glazed to be air tight; a Pt-wound furnace at 110-v. was used. Temp. control was manual, by means of a coarse and a fine rheostat. Temps. were read by means of a Pt-PtRh thermocouple and a millivoltmeter, with a precision of about 5° at 1000° . The reaction tube was connected to a manometer and a vacuum pump by means of a cemented joint; baryta was interposed between the gas space and the cement. The reactions studied were found reversible through the agreement of the equil. pressure when measured after successively raising and lowering the temp. Data reported in this paper cover MgSO_4 , BeSO_4 and their double salts with K_2SO_4 . These compds. all dissociate according to scheme (a). MgSO_4 melts with decompn. at about 1155° , decompn. beginning at about 880° . The heat of decompn. calcd. from the partial pressure of SO_3 is approx. 66 cal./mol. BeSO_4 begins to decompose below 590° , resulting in the formation of 5 BeO. SO_3 , judging from the rate of loss of wt. on heating in air at 700° . The equation $\log p_{\text{SO}_3} = -14907/T - 14.10 \log T + 57.97$ represents the partial pressure of SO_3 reasonably well at temps. up to 750° ; at higher temps. it yields low results. The heat of decompn. calcd. from the partial pressure of SO_3 is about 41 cal./mol. Comparison with results of Plüddemann on the thermal dissoc. of $\text{Al}_2(\text{SO}_4)_3$ (Diss. Berlin 1907) shows that the latter compd. begins to decompose at much lower temps.; its total pressure at 750° is 76.0 cm. Hg. The double salt $\text{MgSO}_4 \cdot \text{K}_2\text{SO}_4$ melts at about 750° , decompn. of the melt beginning at about 895° . The pressures are appreciably lower than that for MgSO_4 , but could not be measured because the melt attacked porcelain. $\text{BeSO}_4 \cdot \text{K}_2\text{SO}_4$ melts at 900° and begins to decompose at about 700° . The heat of decompn. calcd. from the partial pressure of SO_3 below and above the m. p. is 65.2 and 58.8 cal./mol., resp. F. C. K.

Dissociation pressures of hydrated double selenates. JOHN FERGUSON. *J. Chem. Soc.* 127, 2096-2100(1925); cf. *C. A.* 18, 3328.—Vapor pressure measurements in the temperature range 25° to 75° have been made for equilibria of the type: $\text{M}^{II}\text{SeO}_4 \cdot \text{M}^{II}\text{SO}_4 \cdot 6\text{H}_2\text{O} \rightleftharpoons \text{M}^{II}\text{SeO}_4 \cdot \text{M}_2^{II}\text{SeO}_4 \cdot 2\text{H}_2\text{O} + 4\text{H}_2\text{O}$ for the following pairs: Cu-K, Cu-Rb, Cu-Cs, Cu-(NH₄), Cu-Tl, Co-K, Co-(NH₄), Zn-K, Zn-(NH₄), Ni-K, Ni-Rb, Ni-Cs, Ni-(NH₄) and also for nickel ammonium chromate. The stabilities of these salts, as measured by the temp. at which their dissociation pressures, attain the value of 50 mm. are greatly influenced by the mol. and at. vols. of the groups and atoms in the mols. The sp. action of these atoms and groups introduces irregularities especially noticeable for Cs double salts. In general the stabilities increase with increasing vol. of the cation and decrease with increasing vol. of the anion. JAMES M. BELL.

The hypochloric acid and the alkali superchlorides. Notes on the paper by R. Dietzel and F. Schlemmer. O. v. DEINES. *Z. anorg. allgem. Chem.* 149, 99-100 (1925) —The correctness of the statement of Dietzel and Schlemmer (*C. A.* 19, 3441) is disputed, since apparently erroneous conclusions have been drawn from the basic equation representing the action of Cl on NaOH. EMIL KLARMANN

The corrosion of metals by hydrogen chloride and the ammonium halides. K. A. HOFMANN AND FRIDOLIN HARTMANN. *Ber.* 58B, 2466-75(1925); cf. *C. A.* 19, 2309.

—It has been observed previously that NH_4Cl vapor attacks metals at 250 – 300° more than the equiv. amt. of HCl gas. This is due to a considerable adsorption of NH_4Cl on the metal surface. In a contrast to an opinion previously expressed, that the undissociated NH_4Cl mol. reacts with the metal, it is assumed now that an adsorption compd. e. g., $\text{Cu} \dots \text{NH}_3 \cdot \text{HCl}$ first forms. Its thermal dissociation is more likely to be accompanied by a chem. reaction (liberation of H) than that of $\text{Cu} \dots \text{HCl}$. The hydrochlorides of aniline and *N*-dimethylaniline show a much stronger action than NH_4Cl on account of the smaller diffusibility of these amines. Addn. of water, MeOH, EtOH, Et₂O and diphenylamine does not further the reaction. The addn. of 1 mol. NH_3 to 15 mols. HCl increases the production of H a hundred times. If larger surfaces (powd. metal) are exposed to the action of HCl gas, then its action manifests itself much more because of the larger amt. adsorbed. Thus the difference between HCl and NH_4Cl in their action on Cu is better visualized on small surfaces. The particularly pronounced adsorption of NH_4Cl on Cu is due to the affinity of Cu for NH_3 . Thus less H is developed by Sn and HCl under the same conditions despite the greater energy produced by this reaction. NH_4Br and NH_4I , however, produce more H than NH_4Cl , as the heat of formation of CuBr and CuI from Cu and gaseous HBr or HI, resp., is greater than that of CuCl, the conditions of adsorption being very similar for the 3 NH_4 halides. E. K.

The action of gaseous ammonia on phosphorus chlorides. H. PERPÉROT. *Compt. rend.* **181**, 662-4(1925).—Though the final products of the action of NH_3 on P chlorides are complex N compds., it is shown that the initial reaction products are amines. The usual method of passing NH_3 into a CCl_4 soln. of the P chloride was changed so that sep. solns. of the chloride and of NH_3 in CCl_4 were simply mixed and the solid was filtered and dried *in vacuo*. PCl_5 .—The compn. of the product was approx. $\text{PCl}_5 \cdot 10\text{NH}_3$, but a comparison of its decompn. as a function of temp with that of NH_4Cl and extn. of NH_4Cl by liquid NH_3 both indicated that it was a mixt. of $\text{P}(\text{NH}_2)_3$ and NH_4Cl . PCl_3 .—The product was approx. $\text{PCl}_3 \cdot 6\text{NH}_3$, but unlike the thermal decompn. of the $\text{PCl}_5 \cdot 10\text{NH}_3$, the temp.-decompn. curve did not show a section corresponding to the sublimation of NH_4Cl and the product could not be purified with liquid NH_3 . POCl_3 .—The product was $\text{POCl}_3 \cdot 6 \cdot 3\text{NH}_3$, which could not be rendered free of Cl by liquid NH_3 . The results indicate in general that NH_3 transforms P chlorides into amines, but that an intermediate addn. product unstable to heat is perhaps formed, thus: $\text{PCl}_n + 2n\text{NH}_3 \longrightarrow \text{PCl}_n \cdot 2n\text{NH}_3 \longrightarrow \text{P}(\text{NH}_2)_n + n\text{NH}_4\text{Cl}$. WILLIAM T. HALL

Advances in the field of the analytical chemistry of the metalloids in 1924. A. GUTHRIE. *Chem.-Ztg.* **49**, 753-4, 758-60, 861-4, 869-72, 886-8, 906-8, 925-8(1925).—A review with bibliography. E. J. C

Potassium bi-iodate as a volumetric standard. MARCEL KOENIG. *Chimie et industrie Special No.*, 116-7(Sept. 1925).—A standard $\text{KH}(\text{IO}_3)_2$ soln. kept in the dark from June 20, 1920 to July 10, 1925 showed no appreciable loss in strength. During the same period and under the same conditions the strength of a 0.1 N $\text{Na}_2\text{S}_2\text{O}_8$ soln. fell from 0.01340 to 0.01245 g/l. To prep. $\text{KH}(\text{IO}_3)_2$ dissolve 26 g KIO_3 in 125 cc. boiling H_2O , add 21 g. of HIO_3 dissolved in 45 cc. hot H_2O and then 6 drops of concd. HCl , cool rapidly, add 100 cc. of 95% alc., filter through a hardened filter, wash 3 times with 10% MeOH and 3 times with 75% EtOH and dry at 100° . In titrating the soln. addn. of 5 cc. of HCl (d. 1.040) is necessary and sufficient to ensure quant. liberation of I. A. PAPINEAU-COUTURE

Potentiometer indication of the reaction between halogens and the ferrocyanide ion. C. DEL FRESNO. *Anales soc. españ. fis. quim.* **23**, 427-37(1925).—Following by potentiometer the general reaction $2\text{Fe}(\text{CN})_6''' + \text{X}_2 \rightleftharpoons 2\text{Fe}(\text{CN})_6'' + 2\text{X}'$, where X_2 is one of the halogens, has shown that the potential gradient occurs with Cl and Br at exactly the equiv. point according to the above equation, so that either halogen can be titrated with $\text{Fe}(\text{CN})_6$ just as well as the latter can be with the halogen. However, since Cl and Br solns. are unstable the method has no great practical use. With I the above equil. is displaced quantitatively to the right only by an excess of halogen, so that the use of this reaction for potentiometric detn. of I by $\text{Fe}(\text{CN})_6$ is impossible. Also in *Z. Elektrochem.* **31**, 617-21(1925) E. M. SYMMES

A new type of the bimetallic electrode system applied in the potentiometer determination of manganese. KARL SANDVED AND JAN BACKER. *Tids. Kemi Bergv.* **5**, 224-8(1925).—The difference in electrode potentials was produced by using 2 electrodes of widely different surface area, namely a 200 cc. Pt dish contg. the soln. to be examd. and a short 0.4 mm Pt rod dipping in the liquid. In the expts. 25 cc. of a soln. contg. 1.2560 g. Mn per l. was dild. with water and 25-100 cc. of 5 N H_2SO_4 and 8 g. of K^+ $2\text{H}_2\text{O}$ and titrated with 0.1 N KMnO_4 at 80° , the final vol. being 130-150 cc. The initial p.d. was about 0.5 v., increasing during the titration to about 0.7 v. and after the turning point rapidly decreasing towards zero. If more than 40 cc. of 5 N H_2SO_4 was used, the end point was not easy to find. C. A. ROBAK

Examination of some methods for the determination of sulfites and of ferrous iron. W. D. BONNER AND D. M. YOST. *Ind. Eng. Chem.* **18**, 55-6(1926).—Known amts of

sulfite were analyzed by methods involving the use of the following oxidants in the form of standard solns.: KI_3 , KBr_3 , KIO_3 , $HClO_4$, $K_2Cr_2O_7$, $KMnO_4$ and $NaBrO_3$. Good results were obtained with the first 5 and low results with all the others, particularly $KMnO_4$. For the detn. of Fe^{++} it is possible to make use of $HClO_4$ as follows: Add the Fe^{++} soln. to a soln. of Na_2HPO_4 contg. $HClO_4$ $FePO_4$ ppt. Add KI , make acid and titrate with $Na_2S_2O_3$. The Fe is not reduced to any extent by the KI because present in a complex phosphate anion.

W. T. H.

Rapid deduction of small amounts of aluminium in certain non-ferrous materials.

G. E. F. LUNDELL AND H. B. KNOWLES. *Ind. Eng. Chem.* **18**, 60-1 (1926).—For the detection and approx. detn. of 0.01–0.1% Al in non-ferrous alloys the following method is recommended. Dissolve 1 g. of alloy in 5 cc. of concd. HNO_3 . Add 30 cc. of 8% $NaOH$ and boil 1 min. Add 8 cc. of Na_2S soln. (made by satg. the same $NaOH$ soln. with H_2S and dilg. with an equal vol. of $NaOH$ soln.). Swirl the soln. a few mins., filter, make acid with 6 N HCl and add 2 cc. in excess. Digest at 40–60° until the ppt. settles, filter, boil off the H_2S and clear with a little HNO_3 if necessary. Add 10 cc. of 36% $AcOH$ and 5 cc. of 0.2% aurin tricarboxylic acid soln. Finally neutralize with 10% $(NH_4)_2CO_3$ in 5 N NH_4OH , adding 5–10 cc. in excess. Compare the color of the red lake with that produced with known amts. of Al . In the analysis of spelter, good results are obtained with a somewhat modified procedure involving only 1 pptn.

W. T. H.

The chromic acid method for estimating small amounts of bromine.

P. L. HIBBARD. *Ind. Eng. Chem.* **18**, 57–60 (1926).—A simple and rapid method for detg. 0.1–10 mg. of Br is based upon treatment with CrO_3 and a little H_2SO_4 , the evolved Br_2 being caught in KI soln. and the resulting KI_3 titrated with standard $Na_2S_2O_3$ soln. Org. matter should be removed, preferably by treatment with Na_2O_2 and any iodide must be decomposed by treatment with Fe^{+++} and boiling off the I_2 . The chloride concn. must be kept low. Details concerning the app. and procedure are given.

W. T. H.

Practical method for the analysis of commercial nickel.

B. SETLIK AND R. FARSKY. *Chimie et industrie Special No.*, 83 (Sept., 1925).—Dissolve 10–20 g. of sample in 50 cc. HNO_3 (d. 1.3), evap. to dryness, take up in 2–3 cc. HNO_3 and 100 cc. H_2O , filter off SiO_2 and SnO_2 , conc. to 100 cc., add 2 cc. HNO_3 , remove Cu by electrolyzing 3 hrs. under 2 volts, redissolve in HNO_3 any MnO_2 deposited on the anode, remove Al_2O_3 , Fe_2O_3 and MnO_2 by double pptn. with NH_4Cl , NH_4OH and H_2O_2 , conc. the filtrate to a small vol., make slightly acid with HCl , add NH_4Cl and NH_4 phosphate, heat to boiling, add NH_4OH to ppt. MgO (the Ni phosphate redissolves in excess of NH_4OH) which is ignited to $Mg_3P_2O_8$ as usual, remove Zn from the filtrate with H_2S in presence of NH_4CNS and det. Ni electrolytically. Dissolve the ppt. contg. the Fe , Al and Mn in HNO_3 , evap. to dryness, add 50 cc. HNO_3 and 10–15 g. $KClO_4$, evap. to a few cc., slowly add 200 cc. cold H_2O , filter off the Mn ppt., if it is contaminated with Fe , reppt. as above, dissolve in excess of 0.1 N oxalic acid and H_2SO_4 and titrate the excess with $KMnO_4$. Conc. the filtrate from the MnO_2 and ppt. $Al_2O_3 + Fe_2O_3$. This method gave the same results as electrolysis for Ni and as the Briesch-Chalupny method for Mg (*C. A.* **16**, 1374).

A. PAPINEAU-COUTURE

Proper conditions for determining manganese by the ammonium persulfate method.

(MISE) M. COURSANGE AND M. J. NAVARRO. *Chimie et industrie Special No.*, 84–92 (Sept., 1925).—For the detn. of Mn in steels, dissolve 0.2 g. in 20 cc. HNO_3 (d. 1.1), add 1 cc. of satd. (70%) $(NH_4)_2(SO_4)_2$, boil till evolution of O ceases, cool by adding 30 cc. cold H_2O , add 5 cc. 0.1 N $AgNO_3$ and then 1 cc. $(NH_4)_2(SO_4)_2$, either heat on the water bath 3 min. after the soln. turns pink or let stand 30 min., dil. the cold soln. to about 200 cc. and titrate with As_2O_3 . If $AcOH$ is required (e. g., when a large amount of $AgNO_3$ was added to prevent pptn. of MnO_2), add it to the dild. soln. 2 min. before titrating. In cast iron (especially white iron) trouble is encountered on account of C compds. which are formed during soln. of the sample causing low results, and from a certain Mn content MnO_2 ppts. out. This is overcome as follows: dissolve 0.2 g. in 40 cc. of hot HNO_3 (d. 1.2), add 1–2 cc. satd. $(NH_4)_2(SO_4)_2$, boil till evolution of O ceases, add successively 40 cc. cold H_2O , 0.1 N $AgNO_3$ (1 cc. per % Mn) and 2 cc. $(NH_4)_2(SO_4)_2$, either heat on the water bath 5 min. after the soln. turns pink or let stand 30 min., add 2 cc. for 20% $AcOH$, let stand 2 min. and titrate with As_2O_3 . Practically identical results were obtained as by the Volhard method.

Molybdomanganimetry: a new method of microchemical analysis—its principles, reagents and possibilities. G. FONTÈS AND L. THIVOLLE. *Chimie et industrie Special No.*, 93–6 (Sept., 1925).—An outline of the principle of the method, of the prepn. of phosphomolybdic reagent (*C. A.* **15**, 3855; **18**, 3003), and of the possibilities of the method.

A. PAPINEAU-COUTURE

Microchemical molybdomanganimetric determination of metals. G. FONTÈS AND L. THIVOLLE. *Chimie et industrie Special No.*, 97-101 (Sept., 1925).—A detailed description of the methods of detg. Cu and Fe (*C. A.* 18, 3003), with a discussion of the technique. A. PAPINEAU-COUTURE

Microchemical molybdomanganimetric determination of reducing salts. G. FONTÈS AND L. THIVOLLE. *Chimie et industrie Special No.*, 102-5 (Sept., 1925).—Outline of the detn. of Cu as Cu_2O which is not recommended, detn. as Cu (preceding abstract) being preferable. Fe can be detd. as FeO by reducing with Cu in H_3PO_4 soln., cooling, filtering, washing with dil. H_3PO_4 and titrating molybdomanganimetrically. H_3PO_4 completely prevents oxidation in the cold of FeO to Fe_2O_3 . Presence of 1-2 g. Cl does not interfere, but large amts. of SO_3 give high results. If the color of the Cu dissolved during reduction is sufficient to interfere with the titration, ppt. the Fe with NaOH , add a few drops of satd. MgSO_4 soln., filter, redissolve the ppt. in H_3PO_4 and titrate. The methods for detn. of glucose and of lactose are described in detail (*C. A.* 15, 3855; 16, 1788). A. PAPINEAU-COUTURE

The detection of carbonate in bicarbonate with phenolphthalein. V. MACRI. *Boll. chim. farm.* 63, 531-3 (1924); cf. *C. A.* 18, 2788.—It was shown by Mestrezat that the detn. of Na_2CO_3 in NaHCO_3 with phenolphthalein is accurate provided the concn. does not exceed 0.07%. The decolorizing influence of large amts. of salts is very likely due to a salting out of the indicator, since the color reappears on diln. For the pharmacopoeial test a CaSO_4 soln. is suitably added to a 5% NaHCO_3 soln. A Na_2CO_3 content over 4% produces immediately a marked turbidity. MARY JACOBSEN

The remarkable behavior of alkali sulfates in the Kjeldahl determination of nitrogen in nitroaniline. B. M. MARGOSCHES, ERWIN SCHEINOST and MAURYCY FRISCHER. *Ber.* 58B, 2233-7 (1925); cf. *C. A.* 17, 3656.—If 2.0 g. samples of the nitroanilines are treated with 20 cc. concd. H_2SO_4 and various amts. of the alkali sulfates, the % N found increases irregularly from 11-12% with no sulfate added, to 15-18% when 25-40 g. of sulfate are used. Higher results are obtained with K_2SO_4 than with Na_2SO_4 . In all curves the 2.5 g. point for added sulfate is below the 0 point. Equiv. amts. of borax and Na_2SO_4 give check results for N in *o*-nitroaniline (about 0.5 the calcd. figure). While the behavior of *o*-nitroaniline is similar to that of *o*-nitroacetanilide, *p*-nitroacetanilide does not act like *p*-nitroaniline. The amt. of N found in *o*-nitroaniline is independent of the cc. H_2SO_4 used. If the wts. of sample, K_2SO_4 and H_2SO_4 , stand, resp., in the ratios 0.2:10:20, 0.2 15:20, or 0.2:5:20, fairly close checks are obtained in the case of *o*-nitroaniline. As an unexpected development it is found that addn. of HgO to K_2SO_4 decreases the % N obtained. The Kjeldahl reaction yields correct results when the detn. is made on a 0.2 g. sample of *p*-nitroaniline, with 22.5 g. K_2SO_4 and 0.1-0.5 g. CuO . ROSALIE COBB

Color test for nitrous and nitric acids. LAD. EKKERT. *Pharm. Zentralhalle* 66, 733-4 (1925).—0.1 g. of NaNO_2 yields with 5 to 6 cc. of a 33% HCl contg. 0.02 to 0.03 g. resorcinol an immediate saffron-yellow, changing later to brownish red and finally to dark mulberry red, which after a lapse of 20 to 25 min. and addn. of sufficient 0.2 *N* NaOH becomes dark green. An aliquot of the green liquid colors AcMe violet red; another portion develops a rose to onion red with EtOAc ; a 3rd portion becomes on diln. with H_2O violet-red, violet or lilac and eventually green. These solns. then show a fiery red fluorescence with reflected light. If the test soln. contains more resorcinol and the alkali is added after 5 to 10 min. a dark blue color develops, changing gradually to green, then dild. with H_2O to blue with red fluorescence. From 5 to 6 cc. of the same test soln. added to 0.01 g. KNO_3 causes the liquid to assume *only* a pale yellow color after the lapse of 5 min. at the ordinary temp. On heating in a boiling H_2O bath the soln. immediately becomes yellow, then peach red, then in the course of $\frac{1}{2}$ min. dark mulberry red. On treating the cooled liquid with sufficient 0.2 *N* NaOH it becomes dark green. This soln. colors AcMe violet red, EtOAc rose red, becoming on diln. with H_2O violet red or lilac, and showing a fiery red fluorescence with reflected light. On mixing the acid red liquid with a more dil. alkali, the color becomes purple-red, then violet and finally blue, remaining thus even when dild. with H^+O . Other oxidizing agents, as chlorate, develop with the acid soln. an immediate green to red-brown; bromate, a red-brown color; iodate, greenish brown; dichromate, dark green. W. O. E.

Notes on gas analysis, with special reference to the analysis of mine air. J. W. WHITAKER. *Fuel in Science & Practice* 4, 450-4 (1925).—In view of the fact that the Haldane app. (cf. *C. A.* 13, 1197) does not allow the detn. of CO , whereas the Graham app. (cf. *C. A.* 13, 821) detn. only CO , *fractional combustion of CO* in the combustion pipet of the Haldane app. was attempted. CH_4 burns with difficulty unless the Pt is at orange heat and not completely except at a yellow to white heat for 2-3 min. At

dull red CH_4 is unaffected for the first 5 min., whereas small quantities of CO and H are burned completely in 1 min. Furthermore when not over 1% CO or H is present, the temp. rise of the Pt on combustion is not great enough to burn the CH_4 . This latter danger is obviated by an adjustable resistance so that the Pt can be maintained at first non-luminous in the dark, then gradually barely luminous and finally at a dull "fogged" red tint. If the heating is continued many min. at a "fogged red" heat, CH_4 begins to decompose. The CO_2 is then absorbed in KOH as usual. The vol. of CO is that of the CO_2 and the vol. of H is $(2/3)(D-\text{CO}_2/2)$, where D is the total drop in vol. caused by the combustions and CO is the vol. of CO. It was not found possible to burn H separately from CO by adjusting the temp. of the wire. After the CO and H are detd., the CH_4 is estd. in the usual way with the wire at a yellow to white heat and the O is then absorbed by pyrogallol. For the analysis of a mixt conlg unsatd. hydrocarbons, an app. is described and illustrated which is essentially a Haldane app. with 2 additional pipets as recommended by Sinnatt and Slater (cf. *C. A.* 18, 1258). C. C. D.

The determination of small quantities of impurities in argon and nitrogen. G. HEYNE. *Z. angew. Chem.* 38, 1099–101 (1925).—See *C. A.* 19, 3231. H. G.

Sampling malleable iron heats. F. B. BAYLESS. *Chem. Met. Eng.* 32, 882 (1925).—A method is described for getting a sample that will drill easily. W. T. H.

Detection of bismuth in organic material. P. W. DANCKWORTT AND E. PFAU. *Arch. Pharm.* 263, 502–6 (1925).—Treat the sample 24 hrs. in the cold with HNO_3 (1.44), finally heating on the H_2O bath. Evap. the filtrate, and ash the residue together with any material not destroyed by the HNO_3 in a crucible. Dissolve the ash in dil. HNO_3 , add a little CdSO_4 soln. and sat. with H_2S . Since the presence of Cd is not prejudicial to the detection of Bi via Aubry, centrifuge the pptd. sulfide mixt., then wash with H_2O in the same way, dissolve in concd. HNO_3 and evap. to dryness. Dissolve in dil. HNO_3 and test for Bi as follows: Dissolve 1 g. quinine sulfate in 3 drops concd. H_2SO_4 and dil. to 50 cc. by addn. of H_2O . Dissolve 2 g. KI in 50 cc. H_2O . This reagent (made up from equal portions of the 2 solns.) is sensitive to Bi as follows: 0.00001 g. Bi in 1 cc. yields an orange-red ppt., 0.000005 g. Bi a turbidity, 0.000001 g. Bi a weak turbidity discernible only against a white background. In the pptn. of Bi after destruction of the org. matter, the presence of Cu and Fe is quite probable since the former occurs in minute amts. in all organs and would accordingly appear along with the Bi ppt. The same is also true of Fe, at least in minute amt. The presence of Cu in no way impairs the test; that of Fe must, however, be considered since it yields with the quinine reagent a ppt. similar to that of Bi, the ppt. occurring in a diln. of 1:100000. Should both metals be present, the ppt. cannot be differentiated macroscopically, but only by examn. under the microscope. The difference may be detected chemically by treating the ppt. on a cobalt glass with $\text{K}_4\text{Fe}(\text{CN})_6$, whereby the Fe ppt. appears blue while the Cu ppt. remains unchanged as to color. The color contrast becomes more pronounced on treatment with $\text{K}_3\text{Fe}(\text{CN})_6$, which causes the Fe ppt. to disappear on stirring with a glass rod while the Bi ppt. persists. W. O. E.

Micro-methods for the determination of calcium and magnesium in organic liquids. LUIGI CONDORELLI. *Arch. farm. sper.* 40, 71–80 (1925).—*Detn. of Ca.*—Place 1 cc. of blood or other sample in a Pt crucible, evap. to dryness on a water bath and ignite. Dissolve the ash in 0.5 cc. N HCl. By means of a fine pipet bent at right angles, transfer the soln. to a centrifuge tube and rinse out the crucible with 0.5 cc. N HCl and then with 1 cc. H_2O , using the same pipet. Rinse the crucible a 4th and 5th time with 0.5 cc. of 3% $(\text{CO}_2\text{H})_2$. Add a drop of methyl red and place the tube in a boiling water bath, then while hot add N NH_4OH drop by drop from a micro-buret until the soln. is neutral. Add 1 cc. of 8% NH_4Cl and 1 cc. of 9% $(\text{NH}_4\text{CO}_3)_2$. Dil. to 6 cc. with H_2O and allow to stand 24 hrs. Centrifuge 20 min., then pipet off the supernatant liquid, add 5 cc. H_2O and centrifuge again, repeating this operation 3 times. Dissolve the residue in 5 cc. N H_2SO_4 , heat on a water bath and titrate with 0.005 or 0.01 N KMnO_4 . 1 cc. of 0.01 N KMnO_4 = 0.2 mg. Ca. *Detn. of Mg.*—Take an aliquot (e. g., 5 cc.) of the supernatant liquid from the Ca pptn., transfer to a centrifuge tube and add 1 cc. of 25% $(\text{NH}_4)_3\text{PO}_4$ and 2 cc. of 10% NH_4OH . Stir thoroughly and allow to stand 24 hrs. Centrifuge, draw off the supernatant liquid. Rinse the ppt. with 5 cc. of 10% NH_4OH and centrifuge again and repeat this operation twice, testing the final rinse water with molybdic acid and $p\text{-C}_6\text{H}_4(\text{OH})_2$ to assure complete removal of H_3PO_4 . Add 1 cc. of N H_2SO_4 , transfer by means of the pipet to a 25 cc. volumetric flask, washing 5 or 6 times with 1 cc. H_2O . Add 1 cc. of molybdic acid reagent and 2 cc. of a 2% soln. of $p\text{-C}_6\text{H}_4(\text{OH})_2$ in very dil. H_2SO_4 . The color which develops is first yellowish, then greenish blue and reaches its max. intensity in 5 min. Now add 10 cc. of a soln. prepd. by mixing 4 parts of 20% Na_2CO_3 and 1 part of 15% Na_2SO_3 and dil.

to the mark. The azure color is compared colorimetrically with that obtained by treating a standard soln. of KH_2PO_4 (0.0002 *N*) in the same manner. Ratio of heights of columns in the colorimeter $\times 0.4864 = \text{mg. of Mg.}$ A. W. DOX

A few reactions of formaldehyde. N. TARUGI. *Boll. chim. farm.* **63**, 369-74 (1924).—When a slight excess of $\text{Ca}(\text{OH})_2$ slaked in 3 parts water is added to CH_2O and heated with stirring a violent reaction occurs at 95° : $30 \text{ CH}_2\text{O} + 4 \text{ CaO} + \text{H}_2\text{O} = \text{C}_6\text{H}_{12}\text{O}_6\text{CaO} + 2 \text{ C}_6\text{H}_{10}\text{O}_5 + 3 \text{ Ca}(\text{HCOO})_2 \cdot 6 \text{ MeOH}$. If heating is immediately interrupted to avoid further condensation the products are formed in strictly stoichiometrical proportions and the detn. of any of them: total Ca, carbohydrate Ca, H_2CO_3 or reducing sugar affords an exact detn. of the original CH_2O content of the soln. The most rapid method, however, is the detn. of the d. of the end soln. made up to 100 cc. since there is a strictly const. increase with the concn. of CH_2O , the factor being 0.00235 at 15° . Control detns. of CH_2O showed Orchard's method to give the best results, with the understanding, however, that 1 CH_2O ppts. 2 Ag (Tollens). A blank is made to account for the influence of light and the H_2CO_3 content is subtracted from the Ag titer. MeOH does not influence this reaction. MARY JACOBSEN

New color test for tartaric acid. L. EKKERT. *Pharm. Zentralhalle* **66**, 765 (1925).—To a mixt. of 0.01 g. tartaric acid and 0.02 g. pyrogallol add 5 cc. concd. H_2SO_4 , then immerse in a boiling H_2O bath, whereupon an intensely violet color develops. If instead of pyrogallol, β -naphthol is used a blue-green color results. W. O. E

The determination of camphor in plants, industrial products and pharmaceuticals. G. GORI. *Ann. chim. applicata* **15**, 283-300 (1925).—Plants (*Laurus camphora* L., etc.). Even the Giglioli method (*Atti sesto congresso chim. applicata* **4**, 200 (1906)), which is the only one at all reliable for detg. camphor in plants, involves losses of camphor reaching 6-8%. Et_2O is unsatisfactory and CCl_4 is a superior solvent (cf. Gori, *C. A.* **8**, 1140; **9**, 1827, **17**, 672) because Et_2O increases the soly. of camphor in H_2O , whereas CCl_4 reduces its soly. and exts. even traces of camphor sol. in H_2O . Furthermore, instead of tedious phys. sepn. of camphor and camphor oil, the sepn. is much sharper by conversion of all of the components of the oil to compds. sol. in H_2O by oxidation with alc. KMnO_4 . At a low temp. the camphor is not oxidized, while all oil is so. Moisten 200-500 g. of finely divided leaves, bark or roots and distil in a current of steam, maintaining the retort at 160° for 2 hrs. and at 180° for another 0.5 hr. Make slightly alk. with a few drops of 10% KOH , add 3-5 g. of KMnO_4 in H_2O , and keep near 0° for 3-4 hrs., with frequent agitation. Enough KMnO_4 must be used for a permanent violet color. Reduce excess KMnO_4 with SO_2 until colorless, redistil with steam, ext. the camphor in the distillate with 80 g. of CCl_4 , also washing the condensing system. Agitate the combined liquids for some time, sep., filter the CCl_4 layer, wash with CCl_4 and repeat the extn. of the H_2O with 2 more 25 cc. portions of CCl_4 . Evap. the combined exts. at room temp., weigh and maintain over CaCl_2 in an atm. satd. with camphor until of const. wt. The camphor obtained should be pure enough to have a m. p. of 175° . To det. the crude camphor contg. oil the steam distillate is extd. with CCl_4 before oxidation and evapd. to const. wt., after which the oil is oxidized, the camphor detd. and the oil calcd. by difference. *Celluloid*.—Decomp 5 g. of finely divided celluloid with 500 g. of hot 3% KOH , steam distil, ext. the camphor from the distillate with 3 portions of 30, 15 and 15 g. of CCl_4 and proceed as before. *Camphorated spirit*.—Agitate 60 cc. of 10% aq. $\text{Pb}(\text{OAc})_2$ with 10 g. of spirit for 0.5 hr., let stand, ext. with 15-20 g. of CCl_4 and evap. the combined exts. to const. wt. as before. The method is more accurate than that of Jumeau (*Chem.-Ztg.* **1913**, 2174; cf. *C. A.* **8**, 202). *Camphorated oil and ammoniacal liniment*.—Add 500 cc. of H_2O to 10 g. steam distil until exhausted of camphor, ext. the distillate with 30 g. of CCl_4 and proceed as before. *Opodelloch balsam*.—After prolonged agitation of 10-15 g. of balsam with 900 cc. of H_2O and then 100 g. of 10% $\text{Pb}(\text{OAc})_2$ and subsequent standing, steam distil for 2 hrs., ext. the distillate with CCl_4 , evap., and if not pure, oxidize any impurities (e. g., oil of rosemary) with 1 g. of KMnO_4 in 300 g. of H_2O and proceed as before. *Camphorated tablets, pills and gelatin*.—Steam distil the substance suspended or dissolved in H_2O and ext. the distillate with CCl_4 as before. The soly. of camphor in CCl_4 was found to be 0.57:1 at 20° ; in H_2O at 9° , 1.5:1000, in CHCl_3 at 20° , 0.69:1. The soly. of CHCl_3 in H_2O was 0.7-0.9%, depending on the temp. A bibliography of 30 references to previous work relating to the problem in question is included. C. C. DAVIS

Determination of butadiene mixed with other gaseous olefins. B. SOROKIN AND A. BELIKOV. *J. Ind. Chem. (Russia)* **1**, 28-9 (March-April, 1925).—Wash the gas mixt. with H_2O , and 10% NaOH , pass through CCl_4 satd. with dry Cl at $15-16^\circ$, and wash again with 10% NaOH . Combine all the washing liquids, let stand 1.5-2.0 hrs., neutralize excess Cl with Na_2CO_3 , wash with H_2O and dry with CaCl_2 . Evap. the CCl_4

and fractionate the residue. Butadiene gives a tetrachloride, m. 70° , b. $118-22^{\circ}$; the yield is within 2.5-5.0% of the theoretical.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY

Synthesis of cristobalite in the wet way. R. WEIL. *Compt. rend.* **181**, 423-4 (1925).—In a steel tube, modeled after that of C. Friedel and Sarasin, was placed 4 g. of anhyd. pptd. SiO_2 and a soln. of Na_2SiO_3 of a concn less than 1%. After heating to 650° to 750° for 7-15 hrs. and cooling, a mixt. of crystals of quartz and cristobalite in varying proportions was formed. The proportion of cristobalite crystals increases as the concn of the Na_2SiO_3 decreases. With a 1% soln. of Na_2SiO_3 only quartz crystals are formed. The optical characters of the artificial cristobalite are described at length.

L. W. RIGGS

Epsomite from the lower Nord-Ovest mine of Idria. E. ONORATO. *Atti accad. Lincei* [6], **2**, 204 9(1925).—Long silky fibers of epsomite showed: MgO 16.44, CaO trace, SO_3 32.67, H_2O 50.75, and $d = 1.677$; it was, therefore, pure $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$. A white stratified stalactite showed about the same compn. Isomorphous mixts. contained up to 18% $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$. The presence of epsomite in the Triassic of Idria is due to a reaction between MgCO_3 and FeSO_4 produced by the alteration of pyrite.

E. J. WITZEMANN

A new mineral, buttgenbachite. ALFRED SCHOEP. *Compt. rend.* **181**, 421-3 (1925).—This mineral was found as interlaced needles covering cuprite from Likasi, Belgian Congo. It consisted of azure blue crystals with $n = 1.747$ and $d = 3.33$. It loses 0.36% of its wt. after heating several hrs. at 150° . Between 290° and 310° it loses H_2O , nitrous gases and Cu_2Cl_2 up to 20.96% of its wt. Analysis gave: CuO 71.56, Cl 6.02, H_2O 17.34, N_2O_5 5.40, sum 100.32%, which less 1.28, the Cl equiv. of O, leaves 99.04%. The formula is thus $18\text{CuO} \cdot 3\text{Cl} \cdot \text{N}_2\text{O}_6 \cdot 19\text{H}_2\text{O}$, which shows its analogy to connellite. It is named in honor of H. Buttgenbach of the University of Liège.

L. W. RIGGS

Ore deposits of the Saddle Mountain and Banner mining districts, Arizona. C. P. ROSS. U. S. Geol. Survey, *Bull.* **771**, 72 pp.(1925).—These deposits are believed to be genetically related to the intrusion of a quartz-mica diorite. They include Ag-Pb veins, pyritic Au deposits on shear zones, and disseminated pyrite. Contact-metamorphic ore bodies have been mined for Cu, Pb, Zn and Au. V prospects were found. **Copper deposits near Salmon, Idaho.** *Ibid.* *Bull.* **774**, 43 pp.(1925).—The deposits have formed along shear zones partly by replacement and partly by vein-filling. The rare Cu-Fe mineral delafossite is present. The av. ore contains from 2.5 to 6% Cu.

L. W. RIGGS

Alaska's mineral resources and production, 1923. A. H. BROOKS. U. S. Geol. Survey, *Bull.* **773**, 3 52(1925).—The Au, Ag and Cu ores appear to be in large quantities but of rather low grade. Au production is decreasing, while that of Cu, Pb and coal is increasing over pre-war levels.

L. W. RIGGS

Mineral investigations in S. E. Alaska. A. F. BUDDINGTON. U. S. Geol. Survey, *Bull.* **773**, 71-139(1925).—Discoveries of Au, Ni, Pb-Ag and Cu have been made during the past 3 years. **The occurrence of copper on Prince William Sound.** F. H. MOFFIT. *Ibid.* 141-58.—The Cu sulfide deposits of this region are of simple type. The rare mineral chalmersite is widespread. The ore bodies are for the most part of low grade. **Mineral resources of the Kamishak Bay Region.** K. F. MATHER. *Ibid.* 159-81.—Indications of petroleum were found. **The Cold Bay-Katmai District.** W. R. SMITH. *Ibid.* 183-207.—Oil and gas seepages are found. A small Au placer is at Kubugakli. **The outlook for petroleum near Chignik.** G. C. MARTIN. *Ibid.* 209-13.—The outlook is not hopeful. **Geology and gold placers of the Chandalar District.** J. B. MERTIE, JR.

Ibid 215-63.—The Au yield for this district for 1919-1923 ranged from \$10,000 to \$83,000, av. \$30,000 per year. L. W. RIGGS

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST AND R. S. WILLIAMS

Ancient copper mining and smelting in Central Africa. GEO. L. WALKER. *Eng. Mining J.-Press* 120, 811-6(1925). E. J. C.

Action of sodium sulfate in the refining of mats. B. BOGITCH. *Compt. rend.* 181, 666-8(1925).—Treatment of Fe, Ni and Cu with a 1 : 3 mixt. of Na₂SO₄ and SiO₂ for 20-25 min. to a max. temp. of 1400-1500° resulted in the following proportions of the metal being oxidized:

Na ₂ SO ₄ %	10	20	30	50
Fe	18.7%	29.1%	42.3%	67.8%
Ni	10.0	—	29.3	57.2
Cu	6.2	—	17.1	34.1

Oxidation of the Fe and Ni is much higher than would be obtained from the reaction Na₂SO₄ = SO₂ + O + Na₂O, because of subsequent decompn of the SO₂. The following S contents were found in the metals with 10, 30 and 50% of Na₂SO₄, resp.: Fe 1.83, 6.9, 17.5; Fe sulfide (29% S) 30.9, 31.4, 31.2; Ni 2.9, 7.1, 10.2; Ni sulfide (23.5% S) 21.6, 22.2, 22.2; Cu ---, 0.08, 0.07; Pb ---, 0.34, 0.35. The reaction involved in the refining of mats by roasting and smelting is essentially MS + MO ⇌ SO₂ + M, which is reversible. With Cu, equil. is reached when the S content of the metal is very low, with Pb, equil. is reached with a somewhat higher S content, and the reaction is, therefore, somewhat more difficult to carry out commercially; while with Ni (or Co), the S content at equil. is so high that the process cannot be used commercially. The equilibrium in the liquid system iron-copper-manganese for slight variations in carbon contents. F. OSTERMANN. *Z. Metallkunde* 17, 278-82(1925).—By means of microscopic study of ternary Fe-Cu-Mn alloys, contg. varying small amts. of C (0.1 to 1.0% C) O. arrives at the following conclusions. Fe and Cu are miscible in all proportions in the liquid state at temps. not exceeding 20° above the liquidus line. Addn. of C brings about formation of 2 layers, the C going almost exclusively into the layer rich in Fe. As little as 1% C extends the gap in miscibility from 100 to 20% Cu, the upper layer being pure Cu, the bottom layer contg. about 20% Cu. On introducing Mn, which alloys completely with both Fe and Cu in the liquid state, the two-layer system can be changed back to a single liquid phase.

Corrosion of brass in condenser pipes. G. MASING. *Naturwissenschaften* 13, 941-4(1925).—A review. (Cf. Bengough and May, *C. A.* 18, 3352.)

Separating ore particles. J. WEATHERY. U. S. 1,564,731, Dec. 8. In sepg. magnetically permeable particles from gang, the mixt. is passed between a progressive multiphase magnetic field and an induced field. U. S. 1,564,732 specifies a similar process.

Treating ores or residues containing zinc. S. C. SMITH. U. S. 1,565,215, Dec. 8. Liquors (such as those obtained by acid treatment of Zn ores) which contain Zn, Cl and SO_4 ions are treated with $BaCl_2$ to ppt. the SO_4 , then treated with $BaCO_3$ to ppt. $ZnCO_3$ and obtain a soln. contg. $BaCl_2$ for further use on succeeding batches.

Treating argentiferous lead-zinc sulfide ores. F. E. ELMORE. U. S. 1,565,072, Dec. 8. The ore is first heated with NaCl to above 400° (but not high enough to cause volatilization of the Pb as a halogen compd.) in the presence of air. The ZnS for the most part remains unattacked. The oxidized mixt. is extd. with a strong soln. of NaCl and Ag is extd. from the residue with a solvent such as a soln. of $CaCl_2$ or $MgCl_2$ and HCl. U. S. 1,565,073 specifies heating a similar ore to about dull redness under conditions such that the ZnS remains substantially undecomposed, then treating the ore to the "acid brine" process, followed by leaching the argentiferous ZnS residue with acid chloride brine solvents which ext. the Ag and leave the ZnS still substantially undecomposed.

Treating iron ores. W. R. VAN SLYKE. U. S. 1,565,689, Dec. 15. Fe ores are sintered to produce a porous material, mixed with a nonporous fuel such as wood or coal and smelted to recover Fe.

Treating iron sulfide ores containing other valuable metals. A. T. K. ESTELLE. U. S. 1,565,353, Dec. 15. Ore contg. Fe sulfide and which may also contain Cd, Ni, Co, Zn or Cu is heated under nonoxidizing conditions, cooled, comminuted, concd., leached with dil. H_2SO_4 , Cu is removed from the resulting soln., e. g., by pptn. with Fe. Fe sulfate is crystd., the crystd. mass is treated with NH_3 and air, dried, washed and $(NH_4)_2SO_4$ sepd. from metal values and crystd.

Treating manganese-silver ores. M. F. COOLBAUGH and J. B. READ. U. S. 1,562,942, Nov. 24. Ore contg. Mn, Ag and sulfides is heated to a temp. sufficiently high (usually about 600-1000) and for a time sufficient to insure roasting of the sulfides other than Ag sulfide and prevent a dead roast and retain the Ag in the form of sulfide. The solid materials and gases are advanced in the same direction through an inclined horizontal kiln and the temp. is lowered below the decomposing temp. of Mn sulfate so that the S contg. gases will react with the Mn mineral and form Mn sulfate. The latter is leached out of the resulting mixt.

Tin from ores. J. R. STACK. U. S. 1,566,352, Dec. 22. Ore or similar material contg. Sn, Fe and other elements is crushed, heated in a closed receptacle to a temp. above the reducing point of Sn but below the reducing point of Fe and subjected to the action of a gas such as producer gas which will reduce the Sn. The latter is removed and the residue treated to recover its remaining metal values.

Separating copper from alloys with iron. H. PEDERSON. U. S. 1,562,472, Nov. 24. In treating Fe contg. C and Cu alloys to obtain Cu, the alloy is subjected to washing with Pb in a liquid condition so that a Pb alloy, rich in Cu, and Fe, free from or poor in Cu, is obtained.

Exothermic roasting of finely divided ore suspended in gas currents. A. D. H. L. FASSOTTE. U. S. 1,563,616, Dec. 1. Mech. features, adapted for use in connection with roasting of ores contg. S or As.

Apparatus for sintering ores. J. R. LINNEY. U. S. 1,563,759, Dec. 1. Sep. pallets or grates are carried on an endless track.

Rotary kiln and auxiliary apparatus for producing zinc oxide from ore, etc. M. P. KIRK. U. S. 1,566,103, Dec. 15.

Charging cupola furnaces. D. BAKER. U. S. 1,563,949, Dec. 1. Mech. features.

Condenser for zinc vapors. O. RAVNER. U. S. 1,562,473, Nov. 24. A condenser for Zn vapor comprises a revolving drum and a stationary tube connected with the drum in such a manner that the condensate formed in the tube will fall back into the drum.

Zinc condenser. H. A. GRINE. U. S. 1,565,928, Dec. 15. A compn. for making molded Zn condensers comprises broken Zn condenser, Zn ore and a refractory bonding material such as clay.

Still and condensing chamber for manufacturing metal dust from zinc or similar metals. M. H. NEWELL. U. S. 1,566,913, Dec. 22.

Zinc and lead. C. E. CRONELIUS. U. S. 1,566,183, Dec. 15. Vapors of volatile metals such as Zn or Zn and Pb are produced by a reduction process and the vapor, without permitting contact with air, is condensed to a powder and the latter, still out of contact with air, is heated and agitated to convert it into a liquid state.

Ferrovanadium. L. F. VOOR. U. S. 1,564,156, Dec. 1. A molten bath of ferrous metal is formed with an overlying layer of slag contg. V compds. A fluxing material such as lime is then spread over the slag together with finely divided Si-contg. reducing material, *e. g.*, ferro-Si, so that the latter gradually descends through the V-contg. slag and reduces the V.

Refining lead. P. W. DAVIS. U. S. 1,566,078, Dec. 15. A molten Pb alloy which may contain Sb (*e. g.*, old storage battery plate metal) is treated with molten PbO under such conditions that the 2 materials are brought together in the form of small particles, *e. g.*, in a rotating furnace.

Hollow drill steel and similar articles. P. A. E. ARMSTRONG. U. S. 1,565,771, Dec. 15. Mech. features are specified for making a tubular body having a body portion initially consisting of steel relatively high in C and a bore lining initially consisting of steel relatively low in C, substantially homogenized by welding and C equalization under heat treatment.

Heat-resisting steel. E. H. NOACK. U. S. 1,562,782, Nov. 24. A steel adapted for furnace parts, engine valves, etc., contains Si 1.5–2.0, Cu 0.50–1.00, Mn not over 0.12 and C not over 0.10%.

Determining transformation points in heat treatment of steel, etc. C. A. MARTIN. U. S. 1,550,272, Aug. 18, 1925. In order to render observable the occurrence of a crit. or transformation point or points or of the decalescence, recalescence or similar stages in the heat treatment of materials such as alloy steel or low-C steel (whose crit. or transformation points are not sharply defined), a plurality of thermocouples is used in circuit with each other and having junctions disposed in the heating zone at different distances from the mass under heat treatment. These thermocouples are connected to an indicating device which shows variations in the rate of temp. change of the material under heat treatment.

Welding iron and steel. C. H. HUMPHRIES. U. S. 1,563,748, Dec. 1. In welding Fe or steel by gas or electrically, the surfaces to be welded are preliminarily treated with a soln. of chromic acid and allowed to dry.

Open-hearth furnace adapted for refining steel. C. DAVIES, JR. U. S. 1,564,049, Dec. 1.

Detinning tinned-iron scrap. H. DAVIES and M. A. ADAM. U. S. 1,565,425, Dec. 15. The scrap is immersed in a soln. substantially satd. with Fe and Sn chlorides in a stripping vessel and Cl gas is injected.

Deoxidizing metals and alloys. A. PACZ. U. S. 1,562,655, Nov. 24. An intimate mixt. of Al powder and Na fluosilicate is used for refining molten metals such as steel.

Alloys. A. PACZ. U. S. 1,562,654, Nov. 24. In prepg. alloys such as those of Si with Al, a double fluoride of Na and one of the metals to form the alloy, *e. g.*, Na fluosilicate, is treated with Al in a molten bath of the other metal component of the alloy. *e. g.*, Al.

Heat-resisting alloy containing chromium, nickel and iron. N. V. HYBINETTE. U. S. 1,563,573, Dec. 1. An alloy adapted for prolonged use at high temps. comprises Cr 10–20, Ni 30–40, C 0.1–1.5 and Si less than 1%, most of the remainder being Fe.

Aluminium alloy. C. A. FONTANE. U. S. 1,563,079, Nov. 24. An alloy adapted for making cooking vessels comprises Al 95–96, Cu 3–4, Mn 0.2–0.8 and Ag 0.2–0.8%.

Alloy of gold, nickel and iron. C. F. HANSEN. U. S. 1,562,958, Nov. 24. An alloy of good tensile strength and workability, adapted for use in dental work, for making hypodermic needles, etc., is formed of Au 55–75, Ni 15–22, Fe or Cr 0.1–4.0 or more and Mn 1–4 or Mg 0.25–0.50%.

Tungsten-platinum-iridium alloy. E. HAAEGN. U. S. 1,566,534, Dec. 22. An alloy adapted for tipping Au pen nibs is formed of W 80-90, Pt 10-17 and Ir 1-3%.

Copper alloy. C. KAZEMER. U. S. 1,566,406, Dec. 22. Cu is melted with glass and the melt formed into sheets which are reduced in thickness by pressure. The sheets are remelted with an admixt. of Ag and glass, the melt is formed into sheets and these are also reduced in thickness by pressure and then converted into small pieces for further remelting and casting.

Pyrophoric alloy of tin and zirconium. H. S. COOPER. U. S. 1,562,540, Nov. 24. An alloy of Zr with 20-40% of Sn is used for igniters.

Ferrozirconium. R. H. MCKEE. U. S. 1,565,280, Dec. 15. An alloy is produced by fusing an O compd. of Zr, e. g., ZrO_2 , with a metallic sulfide such as FeS and removing S by air blasting.

Alloy for electrical contacts. L. A. GARDNER. U. S. 1,565,358, Dec. 15. Au 75, Ni 16.7, Zn 5.34 and Cu 2.96%.

Deoxidizing aluminium bronze. W. G. HARVEY. U. S. 1,563,188, Nov. 24. The molten metal to be deoxidized is treated with an alloy of Cu and Ca in such proportions that the alloy is brittle and has a m. p. substantially below the m. p. of the metal under treatment. An alloy contg. Cu 50 and Ca 50% may be used.

Preventing corrosion in steam digesters. F. G. RAWLING. U. S. 1,566,118, Dec. 15. Na_2CO_3 , Na phosphate, Na silicate, borate or other Na salt of a weakly ionized polybasic acid is added to an aq. soln. of Na sulfite to be used for pulping wood in a steel vessel, with subsequent addn. of a soln. of NaOH to the contents of the vessel during the cooking operation.

Preventing rust. B. D. AVIS. U. S. 1,565,043, Dec. 8. Instruments such as those used in surgical operations are protected from rust by heating them in a dil. soln. of $NaNO_2$ and Na_2SO_4 .

Removing rust from iron. W. F. WANDEL. U. S. 1,565,536, Dec. 15. Fe is freed from rust preparatory to painting it by covering the metal with a layer contg. cod-liver oil and linsed oil or other drying oil and a basic substance such as Fe oxide and $CuCO_3$ and, after the layer has hardened into a coherent mass, stripping it off with included rust.

Tempering cast manganese steel car wheels or similar articles. J. C. DAVIS. U. S. 1,563,170-1, Nov. 24. A series of streams of tempering fluid is directed against the metal.

Cast sheets or metals of low melting point. C. W. HAZELETT. U. S. 1,531,781, March 31, 1925. Alloys such as those of Pb and Sn (e. g., Pb 93 and Sb 7%) adapted for lining acid tanks are cast into thin sheets which are more durable than rolled sheets of the same compn.

Casting copper. L. SHIPLEY. U. S. 1,564,369, Dec. 8. Molten Cu is poured into open molds and immediately covered closely enough to prevent free contact with the air while permitting escape of occluded gases, during a time sufficient to prevent surface oxidation, rapid cooling and sudden degasification of the Cu.

Gray cast iron. K. SIPP. U. S. 1,564,284, Dec. 8. Ni is added to a casting mixt. in quantity to effect, together with the Si present, the required ptpn. of graphite.

Malleable iron castings. W. J. MILES, JR. U. S. 1,564,437, Dec. 8. Impure Fe is melted and certain of its impurities are removed in a cupola. The molten Fe is caused to run directly from the cupola upon the hearth of an air furnace, striking the latter in a fine stream. The metal is thus freed from Si, P and S.

Armor plate. J. B. JOHNSON and S. DANIELS. U. S. 1,563,420, Dec. 1. In the manuf. of armor plate, before it has reached its final thickness it is subjected to a carburizing operation, then rolled to the required final thickness, further carburized on one side only while the other side is protected, to form a "depth of case" of 10-45% of the total thickness of the plate, then heated to about 850°, quenched in oil, reheated to 760° and quenched in H_2O .

Sintering comminuted tungsten or other refractory metals. W. B. GERO. U. S. 1,566,793, Dec. 22. Particles of W, U, Zr or other similar metals in comminuted form are coated with paraffin dissolved in ether or other volatile protective agent and the particles are then sintered into a coherent form.

Treating zinc-coated materials. E. CORNELL, JR. U. S. 1,565,420, Dec. 15. Materials such as other metals which have been coated with Zn are heated to a temp. (which may be about 135°) sufficient to change the grain structure of the Zn and then worked.

Coating ferrous metals with tin and aluminium. C. W. PFENL. U. S. 1,565,496.

Dec. 15. A Sn-coated ferrous metal is heated until the Sn melts and finely divided Al is mixed with the molten Sn until it can absorb no more.

Coating ferrous metals with aluminium. C. W. PRELL. U. S. 1,565,495, Dec. 15. Al is very finely divided in a bath of kerosene, paraffin, palm oil or other air-excluding film-producing material and the product thus obtained is applied to metals such as sheets of ferrous metal to be coated and the coating is heated.

Mold composition. A. PACZ. U. S. 1,566,420, Dec. 22. Molds for casting metals are formed of material contg. Si and a binding material, both in finely divided form, e. g., from ferro-Si and clay.

Ingot molds. W. H. RAMAGE. U. S. 1,565,755, Dec. 15. Fe ingot molds cast in sand are removed from the sand as soon as they can be safely handled, plunged into a chilling bath of H₂O and annealed by their own heat in an enclosed quiescent atm.

Casehardening. I. H. DERBY and C. B. EDWARDS. U. S. 1,550,952, Aug. 25, 1925. Particles of coal-tar coke or other casehardening material treated with an activator are provided with a C shell by coating with pitch and charring; or the particles may be coated with a Cu shell.

Casehardening. G. C. NIXON. U. S. 1,566,766, Dec. 22. A casehardening material is formed of charcoal, coke or other carbonaceous material impregnated with Na₃PO₄.

Furnace for annealing metal sheets, etc. J. E. MONTGOMERY. U. S. 1,566,160, Dec. 15.

Apparatus for use in hot galvanizing of metal articles. W. G. IMHOFF. U. S. 1,566,749, Dec. 22. A galvanizing kettle of ferrous metal is lined with a protective enamel.

Solder. J. B. SPEED and A. H. FALK. U. S. 1,565,115, Dec. 8. A solder of good strength comprises Ag 8-13 and Sn 92-84 parts. Au or Pd 3% increases the strength and toughness.

Electrode holders for arc welding. A. R. ALLARD. U. S. 1,565,405-6, Dec. 15.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Atomic and molecular asymmetry. J. D. MAIN SMITH. *Chemistry and Industry* 44, 1107-10(1925); cf. C. A. 19, 3392.—Polemical with Mann and Pope (C. A. 19, 3480). C. J. WEST

The preparation of hexachloroethane by the chlorination of ethylene. G. F. MILLER. *Ind. Eng. Chem.* 17, 1182-3(1925).—C₂H₄ with Cl₂ in the presence of ordinary com. active C as catalyst at 300-50°, with 10% excess Cl₂, gives 90% of C₂Cl₆, while at 200° the yield is 69%. WM. B. PLUMMER

The reaction between gaseous methyl ether and hydrogen chloride. JITARO SHIDRI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 9A, 97-119 (1925) (In English).—Friedel (*Bull. soc. chim.* 24, 160, 241 (1875)) obtained results which indicated that the formation of the reaction product Me₂O.HCl between Me₂O and HCl was at a min. when the reactants were mixed in equal vols. Ostwald (*Chemie*, 2nd ed., II, 2, 489) showed that the law of mass action required that the reaction product should be at a max. Expts. gave the following values for the equil. const. *K* of the reaction Me₂O.HCl \rightleftharpoons Me₂O + HCl: 1.4906 at 1° and 0.9959 atm., 1.7224 at 5° and 0.9959 atm., 2.0837 at 9° and 0.9956 atm., 3.1744 at 19° and 0.9955 atm. The equil. partial pressures of Me₂O.HCl were at a max. when the 2 reactants were mixed in equal vols., and diminished with an excess of 1 of them. The calcd. values for the heat of reaction *Q* and the integration const. in the van't Hoff equation were -6275 cal. and 5.5373, resp. T. S. C.

Action of metallic sodium on bromoethylene derivatives. ALBERT KIRRMANN. *Compt. rend.* 181, 671-3(1925).—The compds. RCH:CHBr (I) and RCHBr:CH₂ (II) react easily with Na to form 3 products: (1) a large proportion of RCH:CH₂; (2) RCH:CH in considerable amt. from I and in the merest traces from II and (3) small amts. of condensation products. A doubling according to the Wurtz synthesis does not occur, only RR'C:CHBr (III) yielding erythrene hydrocarbons. The following % yields of C₂H₄, C₂H₂ and erythrene hydrocarbons were obtained: C₇H₁₃Br (I) 56, 12, 0; C₆H₅Br (II) 57, 0.02, 0; C₇H₁₃Br (II) 67, 0.002, 0; C₆H₇Br (III) 25, 0, 34; C₈H₁₁Br (mixture of I and II) 58, 14, 0; C₈H₁₃Br (mixture from dehydration of capryl alc. by ZnCl₂) 64, 3, 6. Each type gave results different enough to give valuable information on an unknown substance. Delacoe in similar expts. with Cl derivs. (*Bull. soc. chim.* [3], 35,

345(1906)) used H_2O to facilitate the action, but for various reasons its presence does not explain the reaction, particularly since the rate of reaction is the same with thoroughly desiccated bromoethylene derivs. Nor can the low yield of C_2H_2 derivs. and the high yield of C_2H_4 derivs. be explained, even by assuming that the solvent takes part in the reaction. The only hypothesis which will explain the products from III is that H is formed from mols. which are attacked deeply, leaving residues which easily fix Br, but an exact interpretation of the facts is unwarranted without further expts. now in progress.

C. C. DAVIS

Method of reaction of nitrosyl chloride. I. Nitrosochlorination by means of nitrosyl chloride. HEINRICH RHEINBOLDT AND OTTO SCHMITZ-DUMONT. *Ann.* **444**, 113-35(1925).— Me_2CO and $NOCl$, alone or in CCl_4 or Et_2O , give $MeCOCCl.NOH$, m. $105-6^\circ$, in 45% yields; while it has no pronounced odor, it has a sharp taste and, finely powd., it strongly attacks the mucous membrane. A fresh aq. solu. gives no color with $FeCl_3$; on standing, hydrolysis occurs and there then occurs the typical hydroxamic acid reaction. With $BzCl$ there results 81% of benzoylchloroisnitrosoacetone, m. $113-4^\circ$. $MeCOPr$ and $NOCl$ give a yellow oil, which gives chloroisnitrosomethylpropyl ketoxime, m. 154° (decompn.). Chloroisnitrosomethylisopropyl ketone, m. 87° . Chloroisnitrosopinacolin, m. $133-4^\circ$ (70% yield); Bz deriv., m. $63-4^\circ$; anilino deriv., m. $103-1^\circ$; (with $NaNO_2$ in dil. H_2SO_4 there results 7-nitro-3-trimethylacetyl-2,4- Δ^2 -benzazoxazine, orange-yellow, m. $154-5^\circ$ (decompn.)); *p*-toluidino deriv., m. $123-4^\circ$ (decompn.). Levulinic acid (2 g.) gives 0.15 g. of the chloroisnitroso deriv., m. $145-6^\circ$, whose *Et* ester, m. 145° (decompn.). $BzMe$ and $NOCl$ in the gaseous state give 24.5% of the chloroisnitroso deriv., m. $132-3^\circ$. Its oxime, m. $193-4^\circ$ (decompn.). Anilino deriv., m. 147° . Bz deriv., m. 91° . Chloroisnitrosomethyl-*p*-tolyl ketone, m. $128-9^\circ$ (32% yield). It is decompd. by alkali, giving *p*- $MeC_6H_4CO_2H$. $NOCl$ and *p*- ClC_6H_4COMe give *p*- $ClC_6H_4CO_2H$ and isonitroso-*p*-chloroacetophenone, m. 127° . $PhCH_2Ac$ likewise gives only an isonitroso deriv. Chloroisnitrosobenzalacetone, m. $121-2^\circ$ (decompn.); it is sol. in 40 parts $CHCl_3$ at 18° , 12 parts at the b. p. Br gives a dibromide, m. $156-7^\circ$ (decompn.). Anilino deriv., yellow, m. $176-7^\circ$. Chloroisnitroso-*p*-anisalacetone, m. $143-1^\circ$ (decompn.); there also results some isonitrosoanisalacetone, yellow, m. 173° . $RCOCH.NOH$ and 2 $NOCl$ give $RCOCCl.NOH$, HCl and 2 NO . With the Me_2CO deriv., the yield is about 55%; with $BzMe$, 51%. $AcCH.NOH$ is not changed by HCl at 0° but on raising the temp., it changes to a yellow oil, which does not react with $NOCl$.

C. J. WEST

Possible errors in the use of biological agents in organic chemistry. A warning. C. B. VAN NIEL AND F. VISSER'T HOOFT. *Ber.* **58B**, 1606-10(1925).—The results of fermentation expts. with yeast can be considered significant and due to the yeast only when the duration of the incubation period is short so that other organisms cannot have increased in sufficient numbers to influence the course of the reaction. Expts. of more than 8-10 hrs'. duration are not permissible since the ratio of lactic acid organisms to yeast may be altered in old cultures so that the lactic acid bacilli predominate. Honig and Tempus (*C. A.* **18**, 2872) have identified the product of the oxidation of glucose by Br as 2-ketogluconic acid on the basis of the production of *d*-arabinose after an 8-day fermentation expt. with yeast. On the basis of their expts. Pringsheim (*Zuckerchemie*, Leipzig (1925)) concludes that Boutroux's acid from glucose is 2-ketogluconic acid and not 5-ketogluconic acid as maintained by B. (*Compt. rend.* **127**, 1224(1898)). With lactic acid organisms, B.'s acid would yield a ketopentose, which would form the same osazone as xylose. Since the m. ps. of the osazones of xylose and arabinose are so similar, the identification as the osazone by H. and T. of arabinose formed in a long continued fermentation by yeast of the oxidation product of glucose, is not adequate to prove their contention as to the structure of the oxidation product. Expts. by the authors failed to demonstrate any fermentation of B.'s acid by yeast in pure culture. H. B. L.

Isomerization of vinyalkylcarbinols, $CH_2:CHCH(OH)R$, to β -allylalkyl alcohols, $CH_3(OH)CH:CHR$. RAYMOND DELABY. *Compt. rend.* **181**, 722-4(1925); cf. *C. A.* **19**, 2185.—The migration of the double bond in alcs. contg. the terminal group $:C(OH)CH:CH_2$ into primary alcs. is easily accomplished (cf. Locquin and Wouseng, *C. A.* **16**, 3305) but poor results are obtained in the conversion of secondary to primary alcs. (cf. Baudrenghien, *C. A.* **16**, 3870; **18**, 525). An attempt to convert vinyl ethylcarbinol to β -ethylallyl alc. by the aid of CCl_3CO_2H gave only a 10% yield. But by applying a method already described (cf. Delaby, *C. A.* **17**, 3159; **18**, 664) this isomerization may be accomplished indirectly, the procedure involving the following reactions: $CH_2:CHCH(OH)Et + Br_2 \rightarrow CH_2BrCHBrCH(OH)Et$ (action of HCO_2Na) $\rightarrow HCO_2CH_2CH(O_2CH)CH(OH)Et$ (heat) $\rightarrow HCO_2CH_2CH:CHEt$ (sapon. by KOH) $\rightarrow CH_2(OH)CH:CHEt$. The operations are very simple and only the final rectification needs

much care. The yield is approx. 20%, taking into account the sec. alc. recovered. By this method it should be possible to prep. other homologs of allyl alc. Among them β -propylallyl alc. should by cautious oxidation give β -propylacrolein, a compd. present in leaves, the synthesis of which has never been accomplished. C. C. DAVIS

Trihydroxytriethylamine oxide and substituted hydroxylamines with hydroxyethyl radicals. L. W. JONES AND G. R. BURNS. *J. Am. Chem. Soc.* **47**, 2966-73 (1925).— NH_2OH and $(\text{CH}_2)_3\text{O}$ at 0° and then at room temp. give about 90% of trihydroxytriethylamine oxide, $(\text{HOCH}_2\text{CH}_2)_3\text{NO}$, m. $104-5.5^\circ$, slightly deliquescent, of decidedly sweet taste, slightly basic to litmus, reduces hot $\text{NH}_4\text{OH}-\text{AgNO}_3$ but not Fehling soln. and restores the color to Schiff's reagent. The Bz deriv. is an oil. *Picrate*, very deliquescent, m. $73-4^\circ$. *Chloroplatinate*, m. 99° to 158.5° . Reduction with Zn dust and H_2O gives $(\text{HOCH}_2\text{CH}_2)_3\text{N}$, which was reoxidized by H_2O_2 to the oxide. $(\text{AcOCH}_2\text{CH}_2)_3\text{N}$, b₂₇ $206-7^\circ$ (*chloroplatinate*, m. 123.5°), is oxidized by BzO_2H to the oxide in almost quant. yield. Decompn. of the oxide by NaOH gave a mixt. of sec. and tert. amine, the former predominating. With HCl there results about 30% of the amine salt. *N,N*-Dihydroxydiethylhydroxylamine is a thick liquid which decomp. when heated and was analyzed as the *picrate*, m. $104-6^\circ$, the *chloroplatinate*, m. $117.5-8^\circ$ and the *tri-Bz deriv.*, a thick liquid. Reduction by Zn dust and H_2O and heating with 70% H_2SO_4 at 165° gives morpholine. *O-Ethyl-N,N*-dihydroxydiethylhydroxylamine, thick liquid, analyzed as the *chloroplatinate*, m. $166-7^\circ$; the liquid fraction of the chloroplatinates appeared to be derivs. of compds. of the type $(\text{HOCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2)_2\text{NOEt}$. *O,N*-Diethyl-*N*-hydroxyethylhydroxylamine, lt $(\text{HOCH}_2\text{CH}_2)_2\text{NOEt}$, b₁₆ 63° , b₇₆₀ 170° (35% yield); *chloroplatinate*, m. $143-3.5^\circ$. EtOCONHOH showed no tendency to react with $(\text{CH}_2)_3\text{O}$ nor could it be alkylated with $\text{HOCH}_2\text{CH}_2\text{OH}$. $\text{EtOH}-\text{KOH}$ gave an acid salt, decomp. on heating. β -Chloroethyl *m*-dinitrobenzoate, m. 92° , from *m*-(O_2N)₂ $\text{C}_6\text{H}_4\text{COCl}$ and $\text{HOCH}_2\text{CH}_2\text{Cl}$. $(\text{CH}_2\text{OH})_2$ and $\text{C}_{10}\text{H}_7\text{NCO}$ give the *urethan*, $\text{HOCH}_2\text{CH}_2\text{COO}-\text{NHC}_{10}\text{H}_7$, m. $102-3^\circ$. J. WEST

Oxonium compounds. D. McINTOSH. *Trans. Roy. Soc. Can. Sec. [3]*, III, **19**, 71-2 (1925); cf. *C. A.* **7**, 2142.—Some compds. of the O derivs. of the aliphatic group with Cl and Br have been prepd. No exceptions to the following rules were found: (1) A monoacid alc. unites with one Br or Cl atom. (2) A ketone or an ether unites with 2. (3) A mol. of an ethereal salt unites with 3. The following compds. with Cl and Br, resp. were isolated (no before the halogen = no. of halogen atoms combined with 1 mol. org. substance; 0 = no. compd. could be isolated): PrOH , Cl, Br; iso- PrOH , 0, 0; MeCOEt , 2Cl, 2Br; MeOAc , 3Cl, 3Br; PrOAc , 3Cl, 3Br; iso- AmOAc , 0 Br; EtCO_2Me , 0, 0; PrCO_2Et , 0, 0; Ac_2O , ?, ?. All the substances above gave with HBr compds. conducting the elec. current. Ethylene glycol yields 2 compds. contg. 1 and 2 mols. HBr to one of glycol but no combination with HCl , HI or with halogens occurs. Glycerol did not combine with either the halogens or halogen hydrides. J. W. SHIPLEY

The organoaluminium compounds: ethyl diiodide and diethyl iodide of aluminium. V. GRIGNARD AND R. L. JENKINS. *Bull. soc. chim.* **37**, 1376-85 (1925).—See *C. A.* **19**, 238. H. G.

Antimonial analogs of the cacodyl series. G. T. MORGAN AND G. R. DAVIES. *Nature* **116**, 499 (1925).—Dimethylstibine cyanide has been prepd. By demethylating dimethylstibine trihalide a new series of alkyl antimonials, in which the metal is associated with only one Me radical, has been obtained. Antimony cacodyl itself has not been isolated in a pure state, although its existence has been demonstrated among the reduction products of dimethylstibine. FLORENCE N. SCHOTT

Preparation of ethers in the aliphatic series. JEAN-BAPTISTE SENDERENS. *Compt. rend.* **181**, 698-700 (1925).—Five more ethers were prepd. from the corresponding alcs. by a method already described (*C. A.* **17**, 1949; **19**, 815, 2194). *Heptyl ether*, $(\text{C}_7\text{H}_{15})_2\text{O}$, in a yield of 75 per 100 of alc. *Cetyl ether*, $(\text{C}_{18}\text{H}_{37})_2\text{O}$, m. 55° , decomp. about 300° . *sec-Pentyl ether* $(\text{BuMeCH})_2\text{O}$, d₄¹⁵ 0.778. Allyl alc. with 20 vol.-% $\text{H}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$ (66° B $\acute{\text{e}}$. H_2SO_4 gave a violent explosion) at 105° gave *allyl ether*, a compd. otherwise very difficult to prep. This indicates that non-satd. alcs., like satd. primary and secondary alcs., can easily be prepd. by this method. The following give the b. p. of the ether prepd. by this method, the temp. of etherification and the vol.-% of 66° B $\acute{\text{e}}$. H_2SO_4 : Et_2O 34.8, 135-40, 100; Pr_2O 87-8, 120-5, 40; Bu_2O 140-1, 123-6, 25; iso- Bu_2O 122-4, 120-2, 20; iso- Am_2O 171-2, 130-5, 10; $(\text{C}_7\text{H}_{15})_2\text{O}$ 261.5, 140-5, 3; $(\text{C}_{18}\text{H}_{37})_2\text{O}$ > 300, 140-5, < 2; *sec-Pr}_2\text{O}* 67-8, 98-100, 15; *sec-Bu}_2\text{O}* 120-2, 103-4, 5; $(\text{BuMeCH})_2\text{O}$ 162, 120, 2.5; *sec-octyl ether* 263-4, 135, 1.5. When the ether has a b. p. much higher than the temp. of etherification it does not distil. The proportion of H_2SO_4 remains const. only when the alc. and the hydrocarbons formed do not distil below this temp.,

a condition occurring with but few alcs. With the others the acid becomes more concd. and hydrocarbons are formed at the expense of the yield of ethers. Under the latter conditions a const. amt. of H_2SO_4 can be easily maintained by a continuous replenishment of the alc., thus giving a *continuous process for industrial use*. C. C. D.

Identification of primary alkyl bromides and iodides. C. S. MARVEL, C. G. GAUERKE AND E. L. HILL. *J. Am. Chem. Soc.* **47**, 3009-11(1925).—Primary alkyl bromides and iodides are easily converted into the corresponding mercuric halides (through the Grignard reagent and HgBr_2 or HgI_2), which are suitable derivs. for identification. The following new *mercuric bromides* were prepd.: *Et*, m. 193.5° (all m. p. are cor.); *Pr*, m. 138° ; *iso-Bu*, m. 55.5° ; *Am*, m. 122° ; *hexyl*, m. 118.5° ; *heptyl*, m. 114.5° ; *octyl*, m. 109° . *Mercuric iodides*; *Pr*, m. 112.5° , *Bu*, 117° ; *iso-Bu*, m. 72° . C. J. W.

Stereoisomerism of quadrivalent sulfur, selenium and tellurium. R. F. GOLDSTEIN. *Chemistry and Industry* **44**, 1011-2(1925).—The recently discovered optically active $\text{MeC}_6\text{H}_4\text{S}(\text{O})\text{OEt}$, explained by Phillips by an electronic model (C. A. **20**, 397), can be explained satisfactorily by Werner's theory (the formulas being analogous to those for the optically active amine oxides). The theory may be extended to Se but not to Te, since in the case of Te 2 valencies appear to be different from the other 2.

C. J. WEST

Bromination products of paraldehyde. A. STEPANOV, N. PREOBRASHENSKI AND M. SHCHUKINA. *Ber.* **58B**, 1718-23(1925); cf. Hibbert and Hill, C. A. **17**, 1434.—Bromination of paraldehyde at -15° to -10° in diffuse daylight gives 60-87% of *dibromoparaldehyde* (I), $(\text{C}_2\text{H}_3\text{OBr})_2 \cdot \text{C}_2\text{H}_4\text{O}$, which at 155° decomps. into BrCH_2CHO and AcH . It b_{10} $126-7^\circ$, b_9 $122-3^\circ$, b_8 $120-1^\circ$, b_{14} $135-6^\circ$, m. 57° , volatilizes with steam and can be sublimed, reduces boiling $\text{NH}_3\text{-AgNO}_3$ but does not react with fuchsin- SO_2 or Fehling soln.; mol. wt. in C_6H_6 from 145 in 0.1742% soln. to 289.6 in a 30.882% soln., in $(\text{CH}_2\text{Br})_2$ from 247.3 to 299 in 0.1592 to 7.6172% soln., resp. In the residues from the purification of the I is obtained as by-product *tribromoparaldehyde*, m. 104° , which, by certain modifications in the method of prep. I, can be made the chief product (44%); it b_{13} 176° , b_8 $164-5^\circ$, mol. wt. in freezing C_6H_6 336-46. BrCH_2CHO , obtained by decompn. of I and purified by distn. in CO_2 , forms a colorless transparent mobile liquid b_{747} $104-5^\circ$, d_4^{20} 1.8414, n_D^{20} 1.4798, perfectly sol in H_2O , strongly attacks the mucous membranes and produces yellow stains on the skin, mol. wt. 119-25, mol. refraction 18.97; 10 min. after distn., however, it becomes turbid, then viscous, and soon crystals. to a white solid polymer, insol in H_2O and org. solvents, m. $136-8^\circ$ (volatilizing), reduces cold $\text{NH}_3\text{-AgNO}_3$ but does not redden fuchsin- SO_2 ; its mol. wt. could not be detd. on account of its insoly. Addn. of AcH to the BrCH_2CHO immediately after distn. markedly retards the polymerization. With 2 mols. H_2O the freshly distd. BrCH_2CHO evolves much heat and soon crystals. to a white mass, m. $47-9^\circ$, sol in H_2O , alc. and Et_2O , insol. in cold C_6H_6 and CHCl_3 (but sol. on heating, with decompn.), contg. two HO groups to every 3 mols. of aldehyde (Zerevitinov) and analyzing for $\text{BrCH}_2\text{CH}(\text{OH})\text{-OCH}(\text{CH}_2\text{Br})\text{OCH}(\text{OH})\text{CH}_2\text{Br}$; the mol. wt. in H_2O (125) indicates that it is completely dissociated (probably into hydrates of the monomer, for the soln. gives no color with fuchsin- SO_2). Direct crystn. of the crude I from EtOH yields as by-product $\text{BrCH}_2\text{CH}(\text{OEt})_2$, b_9 $57-8^\circ$, mol. wt. in $(\text{CH}_2\text{Br})_2$ 180-92.

C. A. R.

Some new derivatives of pentadecylaldehyde. STANISLAV LANDA. *Bull. soc. chim.* **37**, 1235-8(1925).—See C. A. **19**, 3251.

H. G.

Phenyl- α -hydroxycrotonamide. An example of the ether of ketone hydrate. J. BOUGAULT. *Bull. soc. chim.* **37**, 1420-36(1925).—See C. A. **19**, 3265.

H. G.

γ,γ' -Dichlorodipropyl sulfide. G. M. BENNETT AND A. L. HOCK. *J. Chem. Soc.* **127**, 2671-7(1925).— $\text{ClCH}_2\text{CH}_2\text{CH}_2\text{OH}$ and Na_2S in an equal wt. of H_2O , boiled 3 hrs., distd. with steam, made acid with HCl and concd., gave γ,γ' -*dihydroxydipropyl sulfide* (I), viscous oil; *bisphenylurethan*, m. $146-8^\circ$. The steam distillate, boiled with HgO , gives a small amt. of the *mercaptide of γ -hydroxypropyl mercaptan*, m. $132-4^\circ$. The HO groups of I are not replaced by Cl through HCl , PCl_3 , PCl_5 or SOCl_2 , but SOCl_2 with PhNMe_2 gives 83% of γ,γ' -*dichlorodipropyl sulfide* (II), pale yellow oil, b_{14} 162° , d_4^{20} (vac.) 1.175, n_D^{20} 1.5075; *chloroplatinate*, $2(\text{ClC}_3\text{H}_6)_2\text{S} \cdot \text{PtCl}_4$, greenish yellow, m. $83.5-5^\circ$. The *dibromide* is unstable and decomps. on standing overnight. MeI and II give crystals, m. $179-81^\circ$, within 0.5 hr. after mixing; on standing these redissolve, and a viscous oil seps.; the residue did not solidify but with HgI_2 gave *dichlorodipropyl-methylsulfonium mercuric iodide*, yellow, m. $84-8^\circ$. Oxidizing agents transform II into the *sulfone*, m. $65-6^\circ$. II and PhONa give the *di-PhO deriv.*, m. 45° ; *di-p-tolylsiloxy deriv.*, m. $50-2^\circ$; *di-piperidino deriv.*, oily, whose *picrate*, yellow, m. $199-200^\circ$. KCN and II give *thiodibutyric nitrile*. K_2S gives a powder, m. $50-70^\circ$, which may be a

polymer of hexamethylene disulfide; mol. wt. in camphor, 1400, 1740. A comparison of the rates of reaction of II with $(\text{ClCH}_2\text{CH}_2)_2\text{S}$ with NaOH in EtOH shows that, the course of the 2 reactions being assumed to be similar, the latter reacts 60 times as fast as the former.

Ethylhexylacetic acid and its esters. A. W. DOX. *J. Am. Chem. Soc.* **47**, 3008-9 (1925).—*dl*-Ethylhexylacetic acid, b. 252-5°, d_{25} 0.8905. *Me ester*, b. 213-5°; *Et ester*, b. 221-3°, d_{25} 0.8580; *Pr ester*, b. 238-40°, d_{25} 0.8578; *Bu ester*, b. 255-7°, d_{25} 0.8571. The esters do not readily form amides.

C. J. WEST

So-called nitrodibromoethylene and the course of the reaction in the formation of bromo- and chloropicrin from polynitrophenols. HEINRICH WIELAND AND HANS JUNG. *Ann.* **445**, 82-92 (1925).—The compd. termed by Merz and Zetter (*Ber.* **12**, 2046 (1879)) as "nitrodibromoethylene" is hexabromotrinisovaleric acid (I), m. 116-7°, obtained in 40% yields from 1,3,5,2,6-(O_2N)₂C₆H(OH)₂ and Br; mol. wt. in AcOH, 695. Concd. H_2SO_4 , HCl and HNO_3 , Br, SOCl_2 , PCl_5 are without action. In EtOH CO_2 is evolved and Br_2CNO_2 and 1,2,3-tribromo-1,3-dinitropropylene (?) results. In Et₂O also, CO_2 is split off and the same products result as with EtOH. H_2O gives CO_2 , Br_2CNO_2 and α,β -dibromoacrylic acid. PhNH_2 and I give bromonitroacetaldehyde anil, yellow, m. 156°, mol. wt. in PhNO_2 252; with dil. HCl there results BrCH_2NO_2 , PhNH_2 and HCO_2H . This was also synthesized from nitroacetaldehyde anil and Br. In the PhNI_2 reaction there are also formed 1 mol. CO_2 , Br_2CHNO_2 and *p*- $\text{BrC}_6\text{H}_4\text{NH}_2$. PhNIINH_2 reacts similarly to PhNH_2 .

C. J. WEST

Decomposition of oxalic acid by acetic anhydride. E. L. WHITFORD. *J. Am. Chem. Soc.* **47**, 2934-8 (1925).—The decompn. of $(\text{CO}_2\text{H})_2$ by Ac_2O is a reaction of the 1st order, the values of $K \times 10^3$ at 25°, 35° and 45° being 12.8, 37.5 and 110.5. Quinoline, cocaine morphine, alanine, strychnine and brucine formed insol. addn. compds. and the evolution of gas practically ceased. Urea, pyrrole, PhNH_2 , PhNHNH_2 , MeCN, EtCN and PrCN showed no appreciable effect upon the rate of decompn. Impure samples of picoline, lutidine and collidine showed a tremendous positive catalytic effect, the systems remaining homogeneous. $\text{C}_6\text{H}_5\text{N}$ also shows a positive catalytic effect but the reaction is complicated by the formation of a solid phase. The compd. $\text{C}_6\text{H}_5\text{N} \cdot (\text{CO}_2\text{H})_2$ may be prepd. by pptn. from Me_2CO solns. and may be used as a basis for purifying $\text{C}_6\text{H}_5\text{N}$. The extent of the decompn. of $(\text{CO}_2\text{H})_2$ in $\text{C}_6\text{H}_5\text{N}$ solns. by Ac_2O is proportional to the amt. of Ac_2O added. The value of reaction-velocity const. in this system is independent of the amt. of the Ac_2O added. The decompn. is probably preceded by the formation of a mol. compd., $\text{Ac}_2\text{O} \cdot (\text{CO}_2\text{H})_2$, which decompn. into CO, CO_2 and 2AcOH.

C. J. W.

Mechanism of oxidation processes. IX. HEINRICH WIELAND. *IX. Ann.* **445**, 181-98 (1925); cf. *C. A.* **19**, 38.—**I. The mode of action of catalase (with Hans Haussmann).** Although it is generally accepted that the 1st step in the utilization of H is the formation of H_2O_2 , all attempts to isolate or detect H_2O_2 in the cells have failed. The activity of catalase is decreased to nearly $\frac{1}{6}$ by the action of 2 cc. 0.001 *N* HCN per cc. of enzyme soln.; aeration did not increase the activity of the enzyme. The retarding action of H, N, CO and MeNC is also discussed; MeNC decreases the enzyme activity 36% (concn., $1.6/100,000$), which is about the same as HCN in a similar concn. H_2O satd. with CO causes a decrease of 50%. The action of colloidal $\text{Fe}(\text{OH})_3$ solns. upon H_2O_2 is also retarded by HCN (though larger amts. are needed than with the enzyme catalase), but the degree is dependent upon the degree of diln. **II. Mode of action of hydrogen peroxide.** (WITH HERMAN LÖVENSKJÖLD.) *Ibid* 198-201.— $\text{MeCH}(\text{OH})\text{CH}(\text{OH})\text{CO}_2\text{H}$ in NH_4OH is oxidized by H_2O_2 to give about 16% of the theoretically possible AcH; no Me_2CO was detected. This acid may be obtained from crotonic acid and H_2O_2 . These facts indicate that H_2O_2 is capable of adding 2 HO groups to the C atoms in an α,β -unsatd. CO_2H acid.

C. J. WEST

Resolution of an asymmetric arsenic compound into its optically active forms. WM. H. MILLS AND RICHARD RAPER. *J. Chem. Soc.* **127**, 2479-83 (1925).—*p*-Tolylmethylidoarsine, Au-yellow oil, b_{15} 163-5°, canary-yellow, m. 29°; with EtMgBr 100 g. give 50 g. *p*-tolylmethyllethylarsine, b_{15} 117°. Oxidation with KMnO_4 to $\text{HO}_2\text{CCCH}_2\text{As}(\text{:O})\text{EtMe}$ and satg. the soln. with H_2S gives *dl*-*p*-carboxyphenylmethyllethylarsine sulfide, m. 183°; the brucine salt, $[\alpha]_{5461}^{20}$ —5.8°, showed a steady decrease in its rotation until after 12 crystns. it had a value of —19.65°; decompn. with NaOH gives the *l*-acid, m. 175-7°, $[\alpha]_{5780}^{20}$ —19.1°, $[\alpha]_{5461}^{20}$ —21.6° (0.5753 g. in 50 cc. EtOH). The morphine salt, $[\alpha]_{5461}^{20}$ —64.9°, showed —51.1° after 10 crystns.; the *d*-acid from this m. 175-6° and showed $[\alpha]_{5461}^{20}$ 18.7°, 22.4° and 39.4° for $\lambda = 5780, 5461, 4359$ (0.2560 g. in 15 cc. EtOH). The presence of the S atom is regarded as the essential feature which enables the resolution.

C. J. WEST

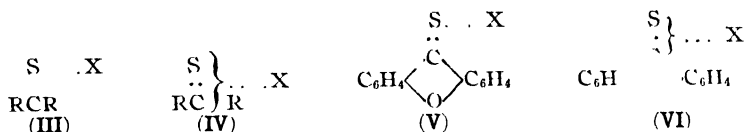

Action of butylmagnesium bromide on the aromatic isothiocyanates. D. E. WORRALL. *J. Am. Chem. Soc.* **47**, 2974-6(1925).—BuMgBr reacts readily and smoothly with aromatic thioisocyanates, forming substituted thioamides of valeric acid. Most of these have an intensely bitter taste. There were prepd. the following *thiovalero derivs.*: *Anilide*, m. 38-9°; *p-toluide*, m. 69-70°; *p-aniside*, m. 62-3°; *p-chloroanilide*, m. 101.5-2°; *p-bromoanilide*, m. 112°; *diphenylamide*, m. 147-8°; *β -naphthylamide*, m. 79-80°. *Bis-thiovalero-p-phenylenediamide*, m. 198-9°. C. J. WEST

Constitution of the Grignard magnesium compounds. III. JAKOB MEISENHEIMER. *Ann.* **446**, 76-86(1925); cf. *C. A.* **19**, 2323.—By means of detns. of n 5% PhCH₂OH can be detd. in PhEtCHOH with an accuracy of about 1%. PhCH₂OH (2 g.) and 2 mols. *p*-O₂NC₆H₄COCl, heated 2 hrs. on the H₂O bath, give only PhCH₂Cl; diln. with 12 cc. Et₂O gives, after 24 hrs' heating, 90% esterification; with 36 cc., after 7 days, 85%. PhEtCHOH and *p*-O₂NC₆H₄COCl alone give 20-25% ester; with 12 cc. Et₂O after 24 hrs. 20% ester; with 36 cc. Et₂O after 7 days, less than 10%. In the formation of the ester care must be taken in washing out the free acid, since the Na salt and the chloride give the *anhydride*, pale yellow, m. 188-9°. PhCOPr is detd. by its 2,4-dinitrophenylhydrazone, red, m. 190-1°. Repetition of earlier expts. gave results similar to those reported. In the decompn. of the cryst. ppt. from 4.4 g. EtBr and 4.2 g. BzH there results 25-50 cc. C₂H₆. No C₂H₄ could be found, but when iso-BuMgBr was used there resulted 12% of Me₂CBrCH₂Br, b. 145-55°. The unsatd. hydrocarbon appears to be formed only during the 1st stages of the reaction. PhEtCHOH (13.6 g.) treated with EtMgBr and then with 5.3 g. BzH give 47% of BzEt and 65% of PhCH₂OH. From the high boiling fraction there was isolated 1,3-diphenyl-1,3-dihydroxy-2-methylpropane, as the *di p-nitrobenzoyl deriv.*, m. 173-4°. C. J. WEST

Basis for the physiological activity of certain -onium compounds. III. Choline derivatives. R. R. RENSHAW AND J. C. WARE. *J. Am. Chem. Soc.* **47**, 2989-95(1925); cf. *C. A.* **19**, 2441.—*Chloroacetylcholine chloroacetate*, markedly hygroscopic, m. 303° (cf. sharp). The physiol. action of most of these compds. has been described by Hunt and Renshaw (*C. A.* **19**, 1912). *Iodomethyl acetate*, b₁₄ 65°, α_{20} 1.902, has distinct lachrymatory properties and decomps. upon distn. at atm. pressure. With Me₃N it gives *acetylformocholine iodide*, m. 152° (cor.); *chloride*, hygroscopic plates, whose *chloroplatinate* forms yellow plates. Hydrolysis with dil. acids gives about 90% of formocholine. Me₃N and ClCH₂CH₂AsCl₂ in PhMe give *dichloroarsylethyltrimethylammonium chloride*, slightly yellow, m. 181.1° (cor.); NaOH gives *arsinsylethyltrimethylammonium chloride*, slightly hygroscopic, cream-colored, m. 194° (cor.). Yields of 89-92% neurine bromide are obtained by the action of 1 mol. equiv. of KOH on bromocholine bromide in abs. EtOH. Br is at first absorbed rapidly when added to an alc. soln. but after about 33% of the calcd. amt. has been added, the velocity of the reaction appears to fall off quickly, which may be due to perbromide formation. Choline chloride and POCl₃ give an extremely hygroscopic compd., probably Me₃N(OPOCl₂)CH₂CH₂Cl, which evolves HCl in the air. C. J. WEST

Organic sulfur compounds. III. Thio ketones. A. SCHÖNBERG (WITH AGNES ROSENBAUM, H. KRÜLL AND UL. OSTWALD). *Ber.* **58B**, 1793-801(1925); cf. *C. A.* **19**, 1424.—This is part of an investigation of the chemistry of the thio ketones as compared with that of the ordinary O ketones. Attempts to prep. thio ketones by the action of free S on a no. of tetraarylethylenes failed, but dioxanthylene (I) and its derivs. on heating with S smoothly yield xanthione (II) derivs. A no. of thio ketones form 1:1 addn. products with HgCl₂; the addn. of the metal salt has a hypsochromic effect, which it is difficult to bring into harmony with the prevailing theories of halochromism. The addn. products of the II are very similar in all their properties to those of the thio benzophenones and the structures III or IV and V or VI (X = inorg. component) are suggested for the 2 series of addn. products, and the addn. products of the 4-thiopyrones, 4-thiochromones and 4-thioflavones are believed to have similar structures. SnCl₄ compds. of benzil derivs. have also been prepd.; they are quickly decompd. by atm. moisture and regenerate their components when treated cold with dil. aq. alkalis. Biphenylenediarylethylenes are formed, with evolution of H₂S, from some thio benzophenones and fluorene. Alkali metals and thio ketones yield colored products very sensitive to air (metal ketyls?). (*p*-MeOC₆H₄)₂CS (VII) with PhMgBr or α -C₁₀H₇-MgBr gives a cryst. substance (VIII), sol. in concd. H₂SO₄ with blue-green color, has no odor, decomp. about 215°, yielding S quant. and (MeOC₆H₄)₂C:C(C₆H₄OMe)₂ (IX); in AcOH suspension with Zn-HCl it gives H₂S and IX; VIII is provisionally assigned the structure of *tetraanisylethylene sulfide*, R₂C.CR₂.S. II is obtained in 80%

yield from I and S at 270° (I does not react with Se in CO₂ at 320° or in boiling CS₂). **2,7-Dimethylxanthione (X)**, m. 188°. **4,4'-Diethoxy-5,5'-dimethylthiobenzophenone (XI)**, from *o*-MeC₆H₄OMe and CS₂ (Gattermann, *Ber.* 28, 2872(1895)), gives 5,4-Me-(EtO)C₆H₃CO₂H, m. 199°, when it is heated in alc. KOH until it is colorless and the resulting product is boiled in PhMe with NaNH₂ and finally hydrolyzed with boiling NaOH. β -Naphthoflavone, obtained in 30% yield from BzCH₂CO₂Et, β -C₁₀H₇OH and P₂O₅ in alc. at 170°, m. 164°, gives with P₂S₅ at 160° 30% of 4-thio- β -naphthoflavone (**XII**), strongly dichroitic needles, m. 149°, forming a green powder and vapor and strongly fluorescent solns. in alc. and C₆H₆. The following *addn. products*, which are odorless, were prep'd. from conc'd. Et₂O solns. of the components: **4,4'-Dimethoxythiobenzophenone (VII)** and **XI** with HgBr₂ and HgCl₂, **II** with HgCl₂, **X** with HgBr₂, all red-yellow. **2,6-Dimethyl-4-thiopyrone-HgBr₂**, colorless. **2,3-Dimethyl-4-thiochromone-HgBr₂**, green-yellow. **XII** with HgBr₂, yellow. *p*-Tolil-SnCl₄, from the components in CS₂, yellow. Anisil-SnCl₄, red. Biphenylenedianisylethylene (2.5 g. from 4 g. **VII** with fluorene at 270°), yellow, m. 148°, sol. in conc'd. H₂SO₄ with red color. Biphenylenebis-[*p*-ethoxyphenyl]ethylene. 9,9'-Dixanthyl is obtained in 1.4 g. yield from 4 g. **II** in AcOH suspension with Zn-HCl.

Correction (dibromosuccinonitrile). ERWIN OTT AND HEINRICH FINKEN *Ber.* 58B, 1703(1925).—Br₂C(CN)₂ (C. A. 12, 3644) takes up 1 mol. H₂O with extraordinary ease, shaken with cold dil. Na₂CO₃; it completely solidifies in a short time with formation of Br₂C(CN)CONH₂, m. 123–4°, identical with the cryst. by-product obtained in the bromination of CH₂(CN)₂ in H₂O and formulated in the earlier paper as dibromosuccinonitrile. The same is true of the by-product, m. 91°, obtained in the chlorination of CH₂(CN)₂, which is, therefore, *dichlorocynoacetamide*. With HBr at 100°, the Br₂C(CN)CONH₂ gives CO₂ and pure Br₂CHCN. C. A. R.

Formaldehyde derivatives of succinimide. E. CHERBULIEZ AND G. SULZER. *Helvetica Chim. Acta* 8, 567–71(1925).—C. and Chambers (C. A. 20, 49) have shown that the acylasparagines undergo rearrangement into acylamino-succinimides, and in the hope of prepg. aminopyrroles from these and analogous compds. derivs. of (CH₂CO)₂NH (**I**) with easily removable acyl groups were prep'd. Ten g. **I** in 10 cc. boiling formalin and a little K₂CO₃, conc'd. *in vacuo* until solid, taken up in 150 cc. boiling PhH, let cool, decanted, and conc'd., gave 13 g. *N*-hydroxymethylsuccinimide (**II**), m. 66°, decamps. into its components in air, or on heating; in C₆H₁₀NH it gives *N*-piperidylmethylsuccinimide, C₆H₁₀NCH₂N(COCH₂)₂, m. 106–7°. **II**, treated with cooling in CHCl₃ with small amts. PCl₅, gives *N*-chloromethylsuccinimide (**III**) b₁₂ 158–60°, m. 58°. *N*-Bromomethylsuccinimide, m. 63–4°. Succinimidomethylpyridinium chloride, decamps. above 65°, m. completely 105°. In CS₂ with AlCl₃ and PhH **III** gives (CH₂CO)NCH₂Ph; heated in alc. with NaOEt it gives *N*-ethoxymethylsuccinimide, b₁₄ 151–2°, b. 262°, m. 31–2°; decompd. by distn. with Zn. In C₆H₅N and Ac₂O **II** gives *N*-acetoxyethylsuccinimide, b₁₀ 170–5°, b. 290°, m. 51°, yields very small amts. of pyrrole bases on distn. with Zn. M. HEIDELBERGER

Constitution of convolvulinic acid. Y. ASAHINA AND M. AKASU. *J. Pharm. Soc. Japan*, No. 523, 779–86(1925).—According to the data published by Taverne (*Rec. trav. chim.* 13, 196), and Hoehncl (*Arch. Pharm.* 234, 647), the constitution of convolvulinic acid (**I**), obtained from Iolop rosin, can be assumed to be MeCH₂CHMe-CH(OH)(CH₂)₈CO₂H. A. and A. repeated the work of T. and H. to det. whether **I** has the side chain. The rosin, obtained from British Drughouse Ltd., was saponified; and the residue was hydrolyzed with dil. H₂SO₄ to obtain **I**. The yield depends upon the concn. of the acid and the temp. of heating. **I** loses its cryst. property when treated with a strong acid at too high a temp. The hydrolysis with 1–0.8% dil. H₂SO₄ at 80–90°, and quick removal of the acid after the decompn. gives the max. yield. **I** thus obtained m. 50°. According to H., when treated with HI and red P, **I** gives a satd. acid C₁₅H₃₀O₂, m. 48°, which H. considers to be a new compd. By the same method of reduction A. and A. obtained a compd. (**II**) which has the same compn., but m. 49.5°. The anilide, m. 78°, exactly the same as pentadecylic anilide. Since the m. p. of the anilide of **II** does not change when mixed with the pure pentadecylic anilide, **II** must be pentadecylic acid, although it m. 2° lower than pure pentadecylic acid. **I** was next

converted to a ketone acid, m. 61° with CrO_3 , and then to oxime, and allowed to undergo Beckmann's rearrangement. When the resulting acid amide is decompd. with HBr , nonanedicarboxylic acid, $\text{C}_9\text{H}_{16}\text{O}_4$, and a small amt. of 2-aminocaproic acid are obtained. I must, therefore, have the structure $\text{Me}(\text{CH}_2)_3\text{CH}(\text{OH})(\text{CH}_2)_3\text{CO}_2\text{H}$, having no side chain. S. T.

Constitution of jalapinic acid. Y. ASAHINA AND J. YAOI. *J. Pharm. Soc. Japan* No. 523, 786-91(1925).—According to Kromer (*J. prakt. Chem.* [2], 57 448), jalapinic acid (I) has a Me group in a side chain. Since K.'s method of identification of methylethylacetic acid as a support for this structure is subject to criticism, A. and A. repeated the work. I was prepd. from scammonium rosin (British Drughouse Ltd.), and reduced with HI and red P. Hexadecylic acid, $\text{C}_{16}\text{H}_{32}\text{O}_2$ (II), m. 61.5° , is obtained. The fact that II is palmitic acid is proved by the mixed m. p. and by the m. p. of its anilide (88°). The position of the OH was next detd. I was oxidized with CrO_3 to the ketone acid, then converted to an oxime and to an acid amide by Beckmann's rearrangement. When the final product was decompd. with HBr , nonanedicarboxylic acid, ω -aminocaproic acid, a small amt. of caproic acid and AmNH_2 (?) were formed. From this, the compn. of I is suggested to be $\text{Me}(\text{CH}_2)_4\text{CH}(\text{OH})(\text{CH}_2)_3\text{CO}_2\text{H}$. S. T.

Configuration of malic acid. ADOLF SONN AND WALTER ROSINSKY. *Ber.* 58B, 1688-90(1925); cf. Freudenberg and Brauns, *C. A.* 16, 3871.—The chloromalic acid (I) obtained by addn. of HOCl to fumaric or maleic acid can be resolved into its components with brucine; replacement of the Cl in the (+)-I gives *d*-tartaric acid, while reduction in the cold yields *d*-malic acid (II), thus establishing the configuration of the latter. Similar results are obtained with the (−)-I. From 13 g. I with brucine in aq. alc. is obtained 15 g. of a brucine salt, prisms with $3\text{H}_2\text{O}$, m. $191-2^{\circ}$, quite stable towards cold H_2O , being unchanged after 10 hrs., but in hot H_2O loses all its Cl in 3 hrs.; $[\alpha]_D^{18} -0.72^{\circ}$ ($\pm 0.01^{\circ}$) (about 6.5% soln. in $\text{C}_6\text{H}_5\text{N}$). Free (+)-I, m. 153° , $[\alpha]_D^{20} 14.0^{\circ}$ [H_2O], $[\alpha]_D^{20} 16.2^{\circ}$ (Me_2CO). *d*-II, from (+)-I in H_2O with a Pt-Zn couple, m. about 100° , $[\alpha]_D^{18} 5.81-5.97^{\circ}$ (Me_2CO). (−)-I, obtained from the filtrate from the above brucine salt, $[\alpha]_D^{19} -7.55^{\circ}$. *l*-II, $[\alpha]_D^{19} -5.75^{\circ}$ ($\pm 0.3^{\circ}$). C. A. R.

Synthesis of the polypeptide-hydantoin tyrosylalaninehydantoin. II. DOROTHY A. HAHN AND ELIZABETH GILMAN. *J. Am. Chem. Soc.* 47, 2941-53(1925); cf. *C. A.* 17, 2106.—In the earlier work it appears that the $\text{MeCHBrCO}_2\text{Et}$ (I) contained appreciable amts. of $\text{BrCH}_2\text{CO}_2\text{Et}$. When this mixt. is heated with the Na deriv. of anisylhydantoin (II), the 1st product which seps is Et 4-anisylhydantoin-1-acetate (III) m. 176° ; prolonged boiling gives mixed crystals, m. $140-2^{\circ}$ (IV), of this and the corresponding propionate. Pure I and II give 70% of Et 4-anisylhydantoin-*N*-1-propionate (V), m. $158-8.5^{\circ}$; 35 g. dissolve in 100 cc. boiling CHCl_3 , 8 g. in 100 cc. boiling EtOH; 6.5 g. III dissolve in 100 cc. boiling CHCl_3 , 3.5 g. in 100 cc. boiling EtOH; 16 g. IV dissolve in 100 cc. boiling EtOH. Hydrolysis of V gives the corresponding acid, m. $255-6^{\circ}$, of which 6 g. dissolve in 80 cc. boiling glacial AcOH. *K* salt, m. 280° (decompn.), of which 4 g. dissolve in 200 cc. boiling 95% EtOH. Catalytic reduction of V (Pd and H in EtOH) gives a mixt. of Et 4-anisylhydantoin-*N*-1-propionates, m. $117.5-8.5^{\circ}$ and $97.5-8.5^{\circ}$; 2.1 g. of the higher melting isomer dissolve in 25 cc. boiling EtOH, the lower melting isomer is much more sol. Hydrolysis gives the corresponding acids, the lower melting ester giving the higher melting acid; the acids, m. $160-1^{\circ}$ and $182-3^{\circ}$; 5 g. of the former and 2 g. of the latter dissolve in 50 cc. boiling H_2O . I, or the acid, heated with HI and red P, gives 2 isomeric 4-hydroxybenzylhydantoin-*N*-1-propionic acids, m. $193.5-5^{\circ}$ and $187-8.5^{\circ}$; demethylation at 100° gives the compd., m. $187-8.5^{\circ}$, while at $130-40^{\circ}$ a mixt. of the 2 is formed. Esterification gives a mixt. of 2 *Et* esters, m. $133-8^{\circ}$ and $152-5^{\circ}$, although the mixt. usually consists of approx. equal amts., sepg. as a cryst. mixt., m. $125-37^{\circ}$. Resolution may be effected by fractional crystn. from dil. EtOH solns. Hydrolysis of the acid or ester gives a mixt. of tyrosine and alanine. C. J. WEST

Isomerization in the hydantoin series induced by the action of hydrogen chloride. DOROTHY A. HAHN AND ELIZABETH GILMAN. *J. Am. Chem. Soc.* 47, 2953-61(1925).—The lower melting form of Et *N*-1-methyl-4-anisylhydantoin-*N*-3-acetate, m. $107-8^{\circ}$, is converted into the higher melting form ($127-8^{\circ}$) by suspending in EtOH and satg. with HCl, the reaction being practically quant. Similarly *N*-1-methyl-*N*-3-methyl-4-anisylhydantoin, m. $91-2.5^{\circ}$, was converted into its isomer, m. $127.5-8.5^{\circ}$; 14.7 g. of this dissolve in 100 cc. boiling EtOH; very slow crystn. gives a 2nd cryst. modification, yellow prisms, which is converted into the colorless needles by crystn. from EtOH satd. with HCl. The reverse transformation by heating the higher melting form with alkali gave a very small amt. of the lower melting form. Both forms gave the same

1,3-dimethyl-4-anisylhydantoin, m. 78-85°, on catalytic reduction; 5 g. of this dissolve in 10 cc. boiling EtOH. The prepn. of the *N*-3-*Me* deriv. of *Me* 4-benzalhydantoin-*N*-1-acetate, m. 66.5-8° and 101-2.5°, will be described later; HCl in EtOH isomerizes the lower melting form into the higher. *Methyl 4-anisalhydantoin-N*-1-acetate, m. 183-4°; it exists in 2 cryst. forms, needles or prisms. In KOH-EtOH with MeI it gives a *Me* deriv., m. 84-5°; 2 g. dissolves in 20 cc. boiling EtOH. HCl in EtOH gives the *isomeric form*, greenish-yellow, m. 129.5-31°. *Methyl 4-anisylhydantoin-N*-1-propionate, m. 163-4°; 20 g. requires 60 cc. boiling CHCl₃, 250 cc. boiling Me₂CO and 600 cc. boiling MeOH for solution. *Me N*-3-methyl-4-anisalhydantoin-*N*-1-propionate, m. 108-4° and 142-3°; the higher melting form is obtained by isomerizing with HCl in EtOH. In the case of the esters studied, the lower melting forms are all very similar in phys. properties and the difference between them and their higher melting isomers is almost const.

C. J. WEST

Thallous salts of lauric and myristic acids. D. HOLDE and K. TAKEHARA. *Ber.* 58B, 1788-91(1925); cf. *C. A.* 19, 2032.—These salts were prepd. in the same way as those of the higher acids and showed the same anomalies in m. ps. Their soly. in 50% alc. is considerable and they cannot, therefore, be used for sepg. lauric and myristic acid from the liquid acids in fats, at least under the conditions of concn. and temp. used for the sepn. of stearic from oleic acid. *Tl myristate*, m. 120-3°, soly. in 50% alc at 25° 0.52-0.54%. *Laurate*, m. 125-6°, soly. 1.46-1.52%.

C. A. R.

Absorption spectra of some derivatives of anisalhydantoin. EMMA P. CARR AND MARIE A. DOBBROW. *J. Am. Chem. Soc.* 47, 2961-5(1925).—From a study of the ultra-violet absorption spectra, it has been shown that the esters obtained by the condensation of MeCHBrCO₂Et with the Na deriv. of anisalhydantoin are *N*-1- and not *N*-3- substitution products, as previously reported by Hahn, Kelley and Schaeffer (*C. A.* 17, 2106). Curves are given from Et 4-anisalhydantoin-*N*-1-acetate, Et 1-methyl-4-anisalhydantoin-*N*-3-acetate and Et 4-anisalhydantoin-*N*-1-propionate.

C. J. WEST

Effect of gum arabic and other emulsifiers on the acid hydrolysis of esters in heterogeneous systems. R. C. SMITH. *J. Chem. Soc.* 127, 2602-5(1925).—The rate of hydrolysis of AcOEt in C₆H₆ by HCl in the presence of solids (lamp black, blood charcoal, kaolin, fuller's earth, pumice, gypsum, BaSO₄, S), irrespective of their soly. in H₂O and C₆H₆, varies but little, being sometimes above and sometimes below the normal value; for S, it increased at first and then diminished; in no case, however, did the deviation from the normal rate exceed 15%. With gum tragacanth and dammar, the normal rate was increased 1.5 times by the latter and more than doubled by the former at a concn. of 1%. With 1% arabic, a slight increase was noticed, but the rate became slower with increasing concn. The rate was diminished by gelatin and isinglass, not appreciably affected by mastic and sandarac and increased by sol. starch. As the concn. of tragacanth increased, the rate increased, even after sufficient gum was present to absorb all the HCl. Numerical results are reported for AcOEt, AcOPr and EtCO₂Et for the gums arabic, tragacanth and dammar and kaolin.

C. J. WEST

Synthesis of 5- β -hydroxyethylbarbituric acid and its alkyl derivatives. L. H. CRETCHER, J. A. KOCH and W. H. PITTEGER. *J. Am. Chem. Soc.* 47, 3083-5(1925).—The following *di*-Et alkylvinylxyethyl malonates, CH₂:CHOCH₂CH₂CR(CO₂Et)₂, were prepd. from RCNa(CO₂Et)₂ and ClCH₂CH₂OCH:CH₂: *Et*, b₁₈ 151°, d₁₆¹⁵ 1.0264; *Pr*, b₁₇ 157°, d₁₆¹⁵ 1.0145; *Bu*, b₁₇ 165°, d₁₆¹⁵ 0.9992; *vinylxyethyl*, b₃ 133°, d₁₆¹⁵ 1.0566. With CO(NH₂)₂ and EtONa there result barbituric acid derivs., which on hydrolysis yield the hydroxyethyl derivs. The following *barbituric acid derivs.* are reported: 2-Thio-5-[ethylvinylxyethyl], m. 136° (all m. ps. cor.); 5-ethylvinylxyethyl, m. 158°; 5-butylvinylxyethyl, m. 141°; 2-thio-5-hydroxyethyl, m. 181° (decompn.); 5-ethylhydroxyethyl, m. 176°; 5-hydroxyethyl, m. above 300°; 2-thio-5-ethylhydroxyethyl, m. 143-5°; 5-propylhydroxyethyl, m. 168°; 5-butylhydroxyethyl, m. 147°.

C. J. WEST

The action of yeast on the glycidic acids. R. KUHN and F. EBEL. *Ber.* 58B, 1447-9(1925).—*cis*- and *trans*-Ethylene oxidicedicarboxylic acids (fumarylglidic acids) on fermentation with bottom yeast, yielded equal amts. of CO₂, while under similar conditions in the fermentation of AcCO₂H, the CO₂ formation was 2-4 times greater. The fermentation of the ethylene oxidicedicarboxylic acids is considered to proceed with the formation of 1 mol. CO₂ and 1 mol. of glycidic acid, which is not further broken down. No MeCHO was produced. Neither AcCO₂H nor the ethylene oxidicedicarboxylic acids were fermented by top yeast.

H. B. LEWIS

Synthesis of two new leucines. KANROKU KURONA. *J. Chem. Soc. Japan* 45, 239-44(1925).—In order to study the mechanism of amino acid fermentation (cf. *C. A.* 20, 213) K. synthesized 2 new leucines that contain tertiary α -NH₂ groups, having an

asymm C (1) *Methylpropyl- α -aminoacetic acid*, $\text{MePrC}(\text{NH}_2)\text{CO}_2\text{H}$. Zelinskii and Stadinikov's method was used (*Ber.* 39, 1722(1906)). Fifty g. MeCOPr , 31 g. NH_4Cl and 38 g. KCN in 200 cc. H_2O and 200 cc. abs. alc. are heated at $50-60^\circ$ for 5 hrs. in a sealed bottle. The contents are then treated with an equal vol. of fuming HCl and satd. with HCl gas while cooling. After standing overnight, they are dild. with H_2O and refluxed for 2 hrs. The product is concd., dried over the steam bath and extd. with abs. alc. The free acid is obtained by the usual method of removing Cl with Ag_2O , Ag by H_2S . The yield was 30 g. It has the compn. $\text{C}_6\text{H}_{13}\text{NO}_2$, m. 295° in a sealed tube, but sublimes in open. The Cu salt is dark green and chars at 200° . The Cu salt is exceedingly sol. in H_2O , fairly in alc., MeOH , hot AmOH , but not in acetone. (2) *Methylisopropyl- α -aminoacetic acid* was prepd. by the same method, from MeCOCHMe_2 . It m. 293° in a sealed tube, sublimes at 290° under atm. pressure. The soly. is exactly same as that of I. Its Cu salt is deep green, very sol. in H_2O and alc. The general phys. properties of these 2 new leucines are the same as those of naturally occurring leucine and isoleucine, making it, therefore, difficult to det. whether these new leucines ever occur in proteins. The exceedingly sol. nature of the Cu salts of these new leucines is probably the only phys. characteristic that might aid in differentiation of these from the already known leucines. S. T.

Mechanism of the oxidation of thymine; 4,5-dihydroxyhydrothymine (thymine-glycol). OSKAR BAUDISCH AND DAVID DAVIDSON. *Ber.* 58B, 1680-4(1925).—See C. A. 19, 2641

Oxidation of isobarbituric acid. A new class of indigoid compounds. DAVID DAVIDSON AND OSKAR BAUDISCH. *Ber.* 58B, 1685-8(1925).—See C. A. 19, 3089.

Oxidation of *d*-glucose by means of copper in sodium carbonate solution (Sol-daine's reagent). F. W. JENSEN AND F. W. UPSON. *J. Am. Chem. Soc.* 47, 3019-24 (1925).—Oxidation of *d*-glucose by means of Cu in the presence of Na_2CO_3 leads to the formation of the same products as in the other Cu oxidations. While hexonic acids are definitely present in the oxidation mixt. they were isolated in much smaller amts. than in the oxidation with Fehling soln. As regards the other products of oxidation there was little difference between these expts. and those with Fehling soln. The oxidation products from 200 g. *d*-glucose, excluding CO_2 , amounted to 142 g., in which the following substances were identified: HCO_2H , 30.86 g.; glycolic acid, 15.3 g.; gluconic acid, 1.2 g.; mannonic acid, small amt.; arabonic acid, 6 g., isolated as the brucine salt; erythronic acid, isolated as the brucine salt and identified as the lactone, 3.6 g.; glyceric acid, 6.2 g., isolated as the brucine salt; *d*-threonic acid, trace. C. J. W.

Preparation of acetacetanilide. HEINRICH PFEIFFER. *J. prakt. Chem.* 111, 240-1(1925).— PhNH_2 (14 g.) and 20 g. $\text{AcCH}_2\text{CO}_2\text{Et}$ are heated 15 min. at 160° ; after cooling to room temp., the flask is cooled in a freezing mixt., giving 50% yields of PhNHCOCHAc , m. 86° . C. J. WEST

Mechanism of carbohydrate oxidation. I. *d*-Glucose, *d*-mannose, *d*-fructose, *d*- and *l*-arabinose and *dl*-glyceric aldehyde. W. L. EVANS, C. A. BUEHLER, C. D. LOOKER, R. A. CRAWFORD AND C. W. HOLL. *J. Am. Chem. Soc.* 47, 3085-98(1925).—An attempt is made to establish, from exact quant. data, obtained under definitely chosen exptl. conditions, the mol. stages through which some of the org. compds. of the more familiar type pass when they undergo this kind of chem. change. When the above named compds. are oxidized with KMnO_4 , the final reaction product in neutral soln. is CO_2 in practically a quant. yield, while in alk. soln. $(\text{CO}_2\text{H})_2$ and a volatile acid also are present; the yield of CO_2 in the case of the hexoses increases with the temp. while that of $(\text{CO}_2\text{H})_2$ decreases; the $(\text{CO}_2\text{H})_2$ reaches a max. yield and the CO_2 a min. one in solns. of KOH of about 0.08 *N*, after which the yield of $(\text{CO}_2\text{H})_2$ gradually diminishes while that of CO_2 shows a corresponding increase; at a concn. of KOH of 1.7-2.0, the yield of $(\text{CO}_2\text{H})_2$ from the oxidation of *d*-fructose at 100° shows a tendency towards a second max., the CO_2 showing a corresponding decrease. Within the limits of exptl. error, the results at 50° are identical for *d*-glucose, *d*-fructose and *d*-mannose and at 75° for *d*-glucose and *d*-fructose, thus offering a verification of the expts. of de-Bruyn and van Ekenstein on the action of alkalies on these 3 sugars. This identity in chem. behavior must be due to the presence of equil. of the same chem. active components in the solns. of the hexoses. This is best explained by the views of Nef, who postulates the existence of a series of enediols, which may undergo splitting and subsequent oxidation in the presence of alkalies and oxidizing agents. The probable mechanism is discussed. II. **The oxidation of *d*-galactose.** WM. L. EVANS AND C. A. BUEHLER. *Ibid.* 3098-101.—*d*-Galactose and *d*-glucose, when oxidized with alk. KMnO_4 at 25° and 50° , do not give the same $(\text{CO}_2\text{H})_2$ - CO_2 ratio at all alkalinities. At 75° the ratio is ap-

prox. the same. The theoretical reasons for this behavior are discussed. **III. The oxidation of the hexitols *d*-mannitol, *d*-sorbitol and dulcitol.** W. L. EVANS AND C. W. HOLL. *Ibid* 3102-5.—In neutral solns. of KMnO_4 the hexitols are practically quant. oxidized to CO_2 ; in alk. solns. $(\text{CO}_2\text{H})_2$ was always present as a final reaction product. The hexitols are more resistant to oxidation than the hexoses. It is probable that the hexitols are oxidized through the intermediate formation of aldohexoses. The results obtained with *d*-sorbitol show that this is oxidized through the intermediate formation of *d*-glucose rather than *l*-gulose. C. J. WEST

Photolysis of ethylene dibasic acids. VOLMAR. *Compt. rend.* **181**, 467-9(1925).—In continuation of previous work (C. A. **19**, 2454) a study was made of various isomeric dibasic acids to det. the influence of the positions (*cis* or *trans*) of the CO_2H groups on the stability towards ultra-violet light. Expts. with succinic, fumaric, maleic, pyrotartaric, mesaconic, itaconic and citraconic acids showed that the ethylenic acids are decompd. more easily than the corresponding satd. acids. The *cis*-isomers are 5-6 times as sensitive to this light as the corresponding *trans*-isomers and represent from the photochem. point of view the labile form. The gas evolved consists almost exclusively of CO . The law of photochem. equivalence (C. A. **18**, 1612) explains the differing behavior of the *cis*- and *trans*-isomers, the latter behaving like a monobasic acid, whereas in the *cis*-isomers the 2 CO_2H groups influence each other spatially. The proximity of the 2 CO_2H groups has, therefore, an influence on the stability of the mol. towards light, whether this proximity involves 2 or 3 dimensions geometrically, which is in accordance with the results of Berthelot (*Compt. rend.* **112**, 287(1891)). If the exposure to ultra-violet light is prolonged, the difference between the *cis*- and *trans*-isomers diminishes because of secondary isomerization, as described by Longworthy and Stoeuner. Thus maleic acid can be detected in solns. of fumaric acid and *vice versa*, the 2 solns. approaching a common state of equil. C. C. DAVIS

Thermal decomposition of acetyl peroxide-succinic acid. F. BRUNNER. *Helvetica Chim. Acta* **8**, 651-4(1925).—The hypothesis that Kolbe's electrochem. synthesis of hydrocarbons (I) was due to the intermediate formation of peroxides and peracids (Fichter and Krummenacher, C. A. **13**, 560) was rendered plausible by F.'s later expts. showing I to be formed when the appropriate peroxide was quickly heated above the explosion point. This is now further tested on a mixed peroxide. $\text{HO}_2\text{CCH}_2\text{CH}_2\text{CO}_2\text{H}$ (Clover and Houghton, *J. Am. Chem. Soc.* **32**, 55(1910)), shaken with Ac_2O until dissolved and dried *in vacuo* over H_2SO_4 and KOH , and the residue washed with abs. Et_2O , gives acetyl peroxide-succinic acid, $\text{HO}_2\text{CCH}_2\text{CH}_2\text{CO}_2\text{OAc}$ (II), indistinctly cryst., *m* 72-5°, explodes 120°. Placed in a bomb, which is described in detail, and plunged into a bath at 180° for 10 min. it gives 94% of the theory of CO_2 and 88.5% of PrCO_2H , analyzed as the Ag salt, the equation being $\text{II} \rightarrow 2\text{CO}_2 + \text{PrCO}_2\text{H}$. The analogy is, therefore, complete with the electrochem. conversion of a mixt. of KOAc and $\text{KO}_2\text{CCH}_2\text{CH}_2\text{CO}_2\text{Et}$ into PrCO_2Et (v. Miller and Hofer, *Ber.* **28**, 2427(1895)). M. H.

Periodicity law and the theory of cyclic unsaturated compounds. P. PETRENKO-KRITSCHENKO. *J. prakt. Chem.* **111**, 23-35(1925).—Theoretical. C. J. WEST

The existence of racemic liquids. F. D. AGUIRRECHE. *Anales soc. españ. fis. quim.* **23**, 409-18(1925).—The *d*-di-Et tartrate and its *dl*-modification were carefully prepd. and the *d*, *n*, surface tension and viscosity of both detd. No differences outside of exptl. error were found. E. M. SYMMES

The structure of benzene. C. W. A. LELY. *Chem. Weekblad* **22**, 357(1925); cf. van Laar, C. A. **19**, 2480.—There is in v. L.'s paper no proof against the triangle formula of benzene. Before more convincing evidence is offered the incidentally doubtful agreement between the calcd. and exptl. value of $10^2\sqrt{a}$ may be considered as a mere coincidence. The fact that C_6H_6 derivs. show the same agreement is only a necessary result of this coincidence, just as all multiples of a number must be divisible by 7, if the number itself is divisible by 7. MARY JACOBSEN

Answer to C. W. A. Lely [structure of benzene]. J. J. VAN LAAR. *Chem. Weekblad* **22**, 357-8(1925); cf. preceding abst.—Lely's argumentation is in striking contrast to the usual method of scientific deduction. The presence of a certain property in a great no. of derivs. is always considered as a proof of this property being inherent to the mother compd. Coincidence is guarded against by the great no. of instances. The 3-ring formula is not disproved but made very improbable. Any other than Kekulé's formula demands a $10^2\sqrt{a}$ so substantially different from 19, that even the critical temp. and pressure of C_6H_6 would be entirely different from the exptl. ones. M. J.

The structure of dihydrobenzenes and related compounds. C. W. A. LELY. *Chem. Weekblad* **22**, 501-7(1925); cf. *J. Chem. Soc.* **85**, 1406(1904); C. A. **3**, 1174; 5,

788; 18, 1991.—Kekulé's benzene formula precludes the existence of

There are, however, indications that these compds. exist. They are formed from *trans*-1,2- and 1,3-dibromocyclohexane. Very likely those of Zelinskii and Gorski, Harries, Crossley and Markovnikov, but only a dibromide, are 1,2, while those of Markovnikov which boil at 100°C. are 1,3 and 1,4. The constitution established by Harries and Harrie method was questioned by Zelinskii and Gorski in view of the oxidation products. The sudden leap in magnetic rotation which occurs between tetra- and dihydrobenzene and has no parallel in the aliphatic series and the difference in Br addn. between the isomeric dienes are suggestive of a peculiar constitution. A comparison of the combustion heats also shows that 25 cal. is consumed for the addn. of the first 2 H. The interpretations of various authors are discussed at length. L.'s theory of synchronous rotation and the triangle formula account very well for these and other phenomena in the aromatic and hydroaromatic series. A 1,2-diene formula for *p*-benzoquinone is developed, based on its behavior towards HCN and Br. Should the existence of 1,2-dienes be proved, then a revision of the entire terpene chemistry would become necessary, the Br addn. serving as a basis for the new classification.

MARY JACOBSEN

Action of nitrous acid upon amides and other "amino" compounds. R. H. A. PLIMMER. *J. Chem. Soc.* **127**, 2651-9 (1925).—Amides and urethan do not react with HNO_2 in the presence of AcOH . Both react quant. in the presence of approx. 2 N HCl . $\text{CO}(\text{NH}_2)_2$ reacts quant with HNO_2 in AcOH . Biuret reacts with 1 N atom in the presence of AcOH , with 2 N atoms in the presence of small amts. of HCl and with 3 N atoms in 2 N HCl . Guanidine and creatine do not react with HNO_2 in AcOH but give off N in HCl . Arginine, excepting its primary $\alpha\text{-NH}_2$ group, behaves in a similar way. Creatinine gives off N corresponding to 1 N atom with HNO_2 in AcOH ; the vol. of N evolved is diminished in the presence of HCl . If HNO_2 in the presence of AcOH is a reagent for the presence of an NH_2 group, amides and the other compds. investigated will possess alternative formulas, which, in the presence of HCl , change to the usually accepted formulas for these compds. C. I. WEST

Spatial relationships about the copper atom. N. SCHLESINGER. *Ber.* 58B, 1877-89 (1925).—S. has made certain observations on the Cu salts of bis-imino acids (I) which can be explained only on the basis of *cis-trans* isomerism, indicating that the 4 atoms or groups united coordinatively to the central Cu atom lie at the 4 corners of a quadrangle (plane configuration) as in the case of the Pt compds. and not at the corners of a tetrahedron (spatial configuration). The **I**, $(\text{CH}_2)_x(\text{NHCCR}'\text{CO}_2\text{H})_2$ (C. A. 9, 74 form, like the NH_2 acids, blue, H_2O -sol. inner complex salts, and also difficultly sol. reddish violet forms with normal mol. wts. Of the **I** with $x = 2$ or 3, only the blue salts are known, of **I** with $x = 10$ only the violet salts, while **I** with x intermediate between the above extremes form both types of salts. The difference between the 2 forms persists even in solns. and the change of the 1 form into the other is shown by the gradual color change of the soln. *Cu chlylenebis-[α -iminoisobutyrate]*, crystals from dil. alc. with $4\text{H}_2\text{O}$, mol. wt. in H_2O 339-41, mol. cond. in H_2O at 25° 4.0-4.3 for V 250. 4.8 for V 500. *Trimethylenebis-[α -iminoisobutyronitrile]* (96% from $\text{CH}_2(\text{CH}_2\text{NH}_2.\text{HCl})_2$ (**II**) and KCN in aq. Me_2CO), m. $91-2^\circ$; *di-HCl salt*. Free acid, threads with $2\text{H}_2\text{O}$, crystals with $1\text{H}_2\text{O}$, does not m. 360° ; *Cu salt*, dark blue crystals with $3\text{H}_2\text{O}$, mol. wt. in freezing H_2O 290.2-7.2. *Trimethylenebis-[α -iminophenylacetoneitrile]* (10.7 g. from 7.35 g. **II**, KCN and BzH in aq. MeOH), m. $97-8^\circ$, smoothly hydrolyzed by fuming HCl to the acid, does not m. 300° , forms a difficultly sol. *di-HCl salt*; *Cu salt*; *di-Me ester* (5 g. as the *di-HCl salt* from 5.5 g. of the acid in MeOH with HCl), m. around $66.5-8.5^\circ$; *di-Et ester*, m. $42.8-3.8^\circ$, forms a *di-HCl salt* which sinters above 200° but does not m. 230° . *Trimethylenebis-[α -iminooctanonitrile]-2HCl*, from **II**, KCN and enanthal (80% yield), decomps. about 185° , m. $215-30^\circ$, decompd. into **II**, HCN and enanthal by hot H_2O ; acid; *di-HCl salt* of acid, decompd. by H_2O , decompd. in a sealed capillary without melting; *Cu salt*; *di-Me ester*, oil. *Di-Me pentamethylenebis-[α -iminopropionate]*, b_{14} 193° , d_{20}^{20} 1.0216, n_D^{20} 1.4533; *di-HCl salt*, becomes yellow on heating, decompd. 173° in a sealed capillary. *Di-HCl salt* of the free acid; *Cu salt*, violet-blue changing to pink on drying but quickly regaining its original color in the air, sol. in molten PhOH with dark blue color, mol. wt. in PhOH 321. *Pentamethylenebis-[α -iminoisobutyric acid]*, does not change 360° ; *di-HCl salt*, decompd. 150° ; *Cu salt*; blue form, prepd. as already described; *violet form*, from as concd. a soln. as possible of the salt $\text{C}_{13}\text{H}_{26}\text{O}_4\text{N}_2\cdot 3\text{C}_2\text{H}_5\text{H}_2\text{O}_4\text{N}_2\cdot \text{Cu}$ (**III**) (obtained by heating the above blue salt, $\text{C}_{18}\text{H}_{24}\text{O}_4\text{N}_2\cdot \text{Cu}$, with H_2O) treated in NH_4OH with exactly the calcd. amt. of $\text{Cu}(\text{OH})_2$ (prepd. from titrated solns. of $\text{Ba}(\text{OH})_2$ and CuSO_4), is unchaned by boiling H_2O .

mol. wt. in PhOH 367–84. In dil. aq. soln., at least, **III** is completely decompd. into its components, its mol. wt. in 2.64% soln. being 308–332. *Ni pentamethylenebis-[α -iminophenylacetate]*, pale grey-green. *Heptamethylenebis-[α -iminopropionic acid]*, crystals with $1\text{H}_2\text{O}$, becomes colored above 270° and decomp.: *di-HCl salt*, exceedingly sol.; *Cu salt*, seps. with $4\text{H}_2\text{O}$. *Heptamethylenebis-[α -iminoisobutyronitrile]*, oil; *di-HCl salt*, m. about 129° (decompn.). *Acid*, does not m. 310° . *Cu salt*; *violet form*, from the acid and exactly the calcd amt. of $\text{Cu}(\text{OH})_2$ in NH_4OH , seps. with $0.5\text{H}_2\text{O}$, sol. in cold C_6H_6 with KMnO_4 -like color changing to blue on heating and back to the original color on again cooling, mol. wt. in PhOH 363–75, converted into the *blue form* by freeing the PhOH soln. of most of the PhOH with H_2O , dilg. with alc., letting stand, and adding Et_2O , can be recrystd. unchanged from alc. but is converted by hot H_2O in a few min. into the violet form, also on longer boiling by alc., is not changed by heating 6 hrs. at 95° in dry form. *Heptamethylenebis-[α -iminophenylacetoneitrile]*, oil (yield, quant.); *di-HCl salt*, m. 144° (decompn.). *Acid*, decomp. about 231° ; *di-HCl salt*; *Cu salt*, obtained only in a light blue, difficultly sol. form; *di-Me ester*, viscous oil, d_4^{20} 1.0854, n_D^{20} 1.5293. *Decamethylenebis-[α -iminoisobutyric acid]* (1.3 g from 3.8 g $\text{CH}_3\text{H}_2\text{N}(\text{CH}_2)_{10}\text{NH}_2\text{HCl}$); *Cu salt*, sol. in PhOH with red color. C A R

Action on dimethylaniline of certain chlorides derived from carbonic acid. H. RIVIER AND P. RICHARD. *Helvetica Chim. Acta* **8**, 490–500 (1925).—*p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{COCl}$ (**I**) was isolated pure for the 1st time by the direct method by passing 1 mol COCl_2 into 2 mols. dry PhNMe_2 (**II**) at 0 – 10° , letting stand several days, adding a little CHCl_3 free from H_2O and alc., filtering *in vacuo* in a desiccator, and washing with CHCl_3 until the more sol. PhNMe_2HCl (**III**) dissolved. It m. 147 – 9° , is extremely deliquescent, passing into the acid; with NaOPh in Et_2O and CHCl_3 free from alc. and H_2O , it gives, on boiling 24 hrs., *Ph p*-dimethylaminobenzoate, m. 180 – 1° ; *picrate*, yellow, m. 146 – 7° . With $\text{Pb}(\text{SEt})_2$ in CHCl_3 at room temp., **I** gives *Et p*-dimethylaminobenzoate, m. 61 – 3° ; *picrate*, yellow, m. 125 – 6° ; with $\text{Pb}(\text{SPh})_2$ the *Ph* analog is formed, decomp. in air; *picrate*, yellow, m. 132 – 3° . **II** and CSCl_2 in CS_2 gave a mixt. from which *p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{CSCl}$ could not be isolated and esters could not be prepd.; it gave 6–8% of the free acid, whose salts decompd., yielding sulfides. Other products were (*p*- $\text{Me}_2\text{NC}_6\text{H}_4$) $_2\text{CS}$, R_2CO and crystal violet. **II** and 2 mols. ClCO_2Et react at 150° with evolution of heat, giving chiefly EtCl and CO_2 with a little MeCl , **II** acting merely as catalyst. The reaction is unfinished after several weeks in the cold. ClCO_2Ph and **II** yield an unstable addn. product, which, on heating at 100° and working up, decomp. according to $2\text{PhNMe}_2\cdot\text{ClCO}_2\text{Ph} + \text{H}_2\text{O} \longrightarrow 2\text{III} + \text{CO}_2 + \text{Ph}_2\text{CO}_3$ and $\text{PhNMe}_2\cdot\text{ClCO}_2\text{Ph} \longrightarrow \text{III} + \text{CO}_2 + \text{PhOH}$. ClCSOEt (**IV**) was prepd. in 53% yield by dropping a 20% soln. of 11.5 g. CSCl_2 in CHCl_3 into 2.3 g. Na in 9.2 g. abs. alc., letting stand 3 hrs., shaking with H_2O , drying and distg.; with 2 mols. **II** in the absence of light it yields EtCl and COS , with a little Et_2CO_3 formed by traces of H_2O . In the rigorous absence of H_2O (distn. of the **II** over Na) equimol. amts. of **II** and ClCSOPh react at 110° with evolution of MeCl , CO , and heat. Kept at 160° for 1 hr., *Ph p*-methylaminobenzoate is formed, yellow, m. 109 – 10° , weakly basic. Similarly at 140° ClCOSEt and 2 mols. **II** give *Et p*-methylaminophenyl sulfide, b_{18} 154 – 6° , b 270 – 5° , pale yellow liquid; *picrate*, m. 130.5 – 1.2° ; *Ph p*-methylaminophenyl sulfide, m. 65.5 – 6.5° , b 345 – 50° (slight decompn.); *picrate*, m. 140° ; *nitrosamine*, yellow, m. 160.5 – 1.0° . At 170° or in the cold ClCS_2Et and 2 mols. **II** evolve EtSH , but only a little Et_2CS_2 and a resin could be isolated. ClCS_2Ph reacted at 100° according to: $2\text{PhSCS}_2\text{Cl} + 4\text{II} \longrightarrow \text{III} + (\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CCl} + \text{Ph}_2\text{CS}_3 + \text{H}_2\text{S}$. M HEIDELBERGER

Preparation of some primary amines by the catalytic reduction of nitriles. W. H. CAROTHERS AND G. A. JONES. *J. Am. Chem. Soc.* **47**, 3051–7 (1925).—Although the reduction of nitriles in the usual solvents commonly leads to a mixt. of primary and sec. amines, *o*- and *p*- $\text{MeC}_6\text{H}_4\text{CN}$, PhCN and PhCH_2CN (when Adam's PtO catalyst is used) are smoothly reduced in Ac_2O with the formation of the Ac derivs. of the corresponding primary amines. Sec. amines or their Ac derivs. are absent. *p*- $\text{MeC}_6\text{H}_4\text{CN}$ gives 88% of *p*- $\text{MeC}_6\text{H}_4\text{CH}_2\text{NHAc}$, m. 110 – 1° (all m. ps. are cor.), from which is obtained 88.7% of $\text{MeC}_6\text{H}_4\text{CH}_2\text{NH}_2$, b_{34} 108° . In glacial AcOH there results 71% of (*p*- $\text{MeC}_6\text{H}_4\text{CH}_2$) $_2\text{NH}$, m. 33.5° . In abs. EtOH there results a mixt. of the 2 products. In Bu_2O , there results 74% of *butyryl-p*-methylbenzylamine, m. 71 – 2° . PhCN in Ac_2O , reduced and hydrolyzed, gives 60% of PhCH_2NH_2 . In glacial AcOH , 41.2 g. PhCN gives 20 g. PhCH_2NH_2 and 12.4 g. $(\text{PhCH}_2)_2\text{NH}$. In abs. EtOH , there result about 5 g. PhCH_2NH_2 and 26 g. $(\text{PhCH}_2)_2\text{NH}$. *o*- $\text{MeC}_6\text{H}_4\text{CN}$ (23.4 g.) gives 30.7 g. $\text{MeC}_6\text{H}_4\text{CH}_2\text{NHAc}$. PhCH_2CN gives about 60% of $\text{PhCH}_2\text{CH}_2\text{NHAc}$. *p*-Methylbenzylamine phenylcarbamide, m. 188 – 8.2° ; *p*-tolylsulfonamide, m. 94.7 – 5.5° ; *p*-bromophenylsulfonamide, m. 126.5 – 7.5° . *o*-Methylbenzylamine phenylcarbamide, m. 167.5 – 8° ; phenyl-

sulfonamide, m. 128.3–9.1°; *p*-tolylsulfonamide, m. 118.7–9.2°; *p*-bromophenylsulfonamide, m. 106.5–7°; β -Phenylethylamine *p*-bromophenylsulfonamide, m. 88.5–9.5°; phenylcarbamide, m. 153.5–4.5°.

C. J. WEST

Nitrogen tetroxide as a reagent for diazotization. BRUCE HOUSTON AND T. B. JOHNSON. *J. Am. Chem. Soc.* **47**, 3011–8 (1925).— N_2O_4 reacts with primary aromatic amines in anhyd. C_6H_6 to form the corresponding diazonium nitrate and diazoaminobenzene combinations. The mechanism of these changes is satisfactorily explained by assigning to N_2O_4 the structure of nitrosyl nitrate, $ON \cdot O \cdot NO_2$. With $m\text{-}O_2NC_6H_4NH_2$ and N_2O_4 there results 3,3'-dinitrodiazoaminobenzene, yellow, m. 195–6° (violent decompn.), mol. wt. in boiling Me_2CO , 282. The 4,4'-deriv., m. 225–30° (decompn.), the 2,2'-deriv., 196°. In the reaction there also results the corresponding diazonium nitrate, the relative amts. of the 2 compds. formed being dependent upon the mol. proportion of the N_2O_4 used in the reaction. Of the 3 isomers, the *o*-deriv. reacted far less smoothly with N_2O_4 than its 2 isomers. Further data from the literature are quoted to support the proposed structure of N_2O_4 .

C. J. WEST

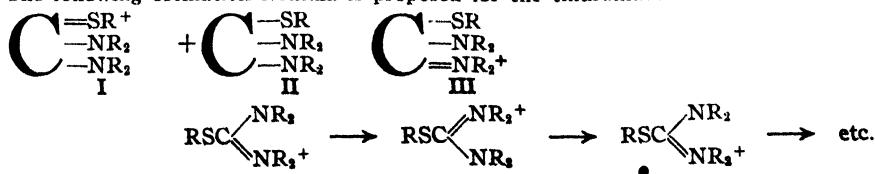

Benzoyl peroxide and secondary amines. STEPHAN GAMBARJAN. *Ber.* **58B**, 1775–8 (1925); cf. *C. A.* **4**, 317.—G. had shown that Bz_2O_2 and Ph_2NH give *o* HOC_6H_4NPhBz , which he assumed to be a rearrangement product of Ph_2NOBz , formed primarily. That this assumption was correct is now shown with a no. of other secondary amines in which the reaction is not complicated by rearrangements. Thus, piperidine with 0.5 mol. Bz_2O_2 in Et_2O gives 95.9% $BzOH$ and 50.2% *O*-benzoyl-*N*-hydroxypiperidine, $C_8H_{10}NOBz$, m. 62°, which reduces Fehling soln. and with $Zn\text{-}AcOH$ in boiling $MeOH$ gives 97.90% $BzOH$ and 98.12% piperidine (as the HCl salt). Again, $NHfEt_2$ with Bz_2O_2 gives 95.9% $BzOH$ and *O*-benzoyl-*N*,*N*-dicylhydroxylamine, oil isolated as the bisulfate (yield, 77.6%), m. 134°, which on reduction gives 98% $BzOH$ and 95.6% $NHfEt_2 \cdot HCl$. Finally, (iso- Bu) $_2NH$ yields *O*-benzoyl-*N*,*N*-disobutylhydroxylamine, whose bisulfate m. 123°.

C. A. R.

Stereochemical studies. IX. Carbothionmalic acids. BROR HOLMBERG. *Ber.* **58B**, 1822–33 (1925), cf. *C. A.* **17**, 1235.—Various alc. acids add CS_2 in alk. soln. with formation of α,Δ -dithiocarbon- or carbothionlonglycolic salts which with alkyl halides yield the acid esters $HO_2CCH_2OCS_2R$ (I); these are unstable and on heating in aq. soln. slowly, in neutral and still more in alk. soln. more rapidly decomp. according to the equations $I + 2H_2O = HO_2CCH_2OH + CO_2 + H_2S + HSR$ or $2I + 2H_2O = 2HO_2CCH_2OH + CO_2 + H_2S + CS(SR)_2$, while with NH_3 and amines they often give only $HSR + NH_4O_2CCH_2OCSNH_2$. The present paper deals with the application of these reactions to malic acid. The reaction with CS_2 is quite slow and considerable amts. of alk. carbonate and trithiocarbonate are formed but by treatment of the product with $EtBr$ is obtained some *mono-Et carbothionmalate* (II) (I, $R = Et$); the compd. obtained from ordinary or *l*(-)-malic acid is *d*-rotatory and is, therefore, to be designated as the *l*(+)-form, in accordance with Wohl and Freudenberg (*C. A.* **17**, 1208; in his preliminary paper, B. designated it as the *l*-form); on decompn. it regenerates the *l*(-)-malic acid. The Et ester of the corresponding *l*(+)-dimethylamide, $HO_2CCH_2OC(SNMe_2)$ (III), gives with $BrCH_2CO_2H$ a *d*-rotatory Et bromosuccinate, which can also be obtained directly from the *d*-rotatory free acid (IV) and can be hydrolyzed to this acid; there, therefore, now seem to be sufficient chem. grounds for calling IV the *l*(+)-form, and the same is true for the *d*-rotatory chloro- and iodosuccinic acids. II (7–8 g., together with about 7 g. $CS(SEt)_2$, from 27 g. malic acid and 3 mols. aq. $NaOH$ (turbined 2 days with 1 mol. CS_2 , then 2 days with 20 g. $EtBr$), pale yellow, m. 147–8° on slow, 150–1° on rapid heating, soly. in H_2O at 25° 24.98 g. per l., $[\alpha]_D$ at 17–8°, 26.55–28.2 in alc., 24.8° in $AcOEt$, 33.5° in Me_2CO , 44.1° in H_2O , $[\alpha]_D$ in aq. soln. half neutralized with KOH 28.9°, fully neutralized with KOH 51.5°, with $Ba(OH)_2$ 47.7°; acid $PhNH_2$ salt, $C_{14}H_{17}O_6NS_2 \cdot H_2O$ (3.1 g. II and 1.0 g. $PhNH_2$ in H_2O); attempts to prep. the neutral salt by using only 1.2 g. II gave the same product, m. 89–91°, loses its H_2O and apparently some $PhNH_2$ over H_2SO_4 , $[\alpha]_D$ 69.8°. Heated 5 hrs. at 122°, 0.5469 g. II loses 0.0290 g. in wt. and it now m. 145–50° and shows α_D 0.05° (0.5 g. in 10 cc. alc.); after evapn. of the alc. and recrystn. from H_2O , the product m. 150–3° (foaming) and its soln., neutralized with $Ba(OH)_2$, shows $[\alpha]_D$ 13.1°, corresponding to a mixt. of 27.5% II and 72.5% of the *dl*-form. The $2\alpha_D$ of a soln. of 0.4220 g. II in 25 cc. H_2O on the H_2O bath changes from 1.49° in 0 hrs. to 0.51° in 31 hrs., that of the acid K salt at 35° from 1.20° to 1.18° after 24 hrs. and 1.16° after 1 week, and that of the neutral K salt (2.13°) remains the same after 24 hrs. and is still 2.09° after 1 week. The racemization in these cases is accompanied by considerable decompn. *dl*-II (25.4 g. from about 90 g. *dl*-malic acid), faintly S-yellow, m. 161–2° on slow, 163–4° (decompn.) on rapid heating, soly. in H_2O at 25° 5.99 g. per l.; *Ba* salt, $C_7H_8O_5S_2Ba$; acid $PhNH_2$ salt, needles

with $1\text{H}_2\text{O}$, m. $85-7^\circ$. *l*(+)-Dimethylamidocarbothionmalic acid (**III**) (10.5 g. crude or 5.3 g. pure product from 12 g. **II** and aq. NHMe_2), prisms or tables with $1\text{H}_2\text{O}$, m. $75-8^\circ$ to a semisolid mass, resolidifies and m. again about 110° (foaming), m., anhyd., $117-8^\circ$ (decompn.), $[\alpha]_D$ in alc. 50.9° , in H_2O 28.55° , in soln. half neutralized with NaOH 7.9° , fully neutralized 7.0° . *Et* ester, from the dried acid with EtOH-HCl , rather thick oil, $[\alpha]_D$ 35.9° (alc.); the 0.5 α_D of a mixt. of this ester and 2 mols. $\text{BrCH}_2\text{CO}_2\text{H}$ in boiling C_6H_6 changed from 5.42° (0 hrs.) to -0.12° after 28 hrs.; the course of the rotation curve (ordinates = rotation, abscissas = time), which falls steeply to 0.30° in 14 hrs., indicates that at least 2 coupled reactions are taking place, probably the formation of a *d*-rotatory bromosuccinic ester, which is then gradually racemized, while an addn. product, formed first, is not capable of existence sufficiently long to have an appreciable influence on the rotation. In a similar expt. in which the heating was continued only 3 hrs. there was isolated from the product a not quite pure *Et* bromosuccinate (Br , 30.41%), b_{13} $125-30^\circ$, d_4^{20} 1.351, $[\alpha]_D$ 29.2° (the higher boiling fractions showed no higher *d* rotation); *Et d*(-)-bromosuccinate, from ordinary asparaginic acid, NaNO_2 and HBr and subsequent esterification with $\text{EtOH-H}_2\text{SO}_4$, b_{12-4} $125-6^\circ$, d_4^{20} 1.350, $[\alpha]_D$ -31.0° . *dl*-Form of **III** (3.4 g. crude or about 2 g. pure product from 4.8 g. *dl*-**II**), tables or prisms with $1\text{H}_2\text{O}$, m. $76-8^\circ$ or, anhyd., $116-7^\circ$ (gas evolution) *l*(+)-Diethylamidocarbothionmalic acid (14.7 g. crude and about 10 g. pure product from 12 g. **II**), tables with $1\text{H}_2\text{O}$, m. $52.5-3.5^\circ$ or, anhyd., $70-2^\circ$, $[\alpha]_D$ 58.4° in alc., 44.4° in H_2O , 25.9° in soln. half neutralized with NaOH , 34.0° in fully neutralized soln. *dl*-Form (4.5 g. crude product from 4.8 g. *dl*-**II**), m. $122-1^\circ$ (gas evolution). **X. l**-Menthylxanthogenamides. BROR HOLMBERG AND WILHELM ROSÉN. *Ibid* 18:34-42; cf. C. A. 19, 56 — *l*-Menthylxanthogenacetamide, from *l*-menthol in xylene turbined 5 hrs. with Na at $140-50^\circ$, then cooled to 30° and treated with CS_2 , the resulting Na xanthogenate (**I**), after drying, being in turn treated in alc. with $\text{ClCH}_2\text{CONH}_2$, very faintly yellowish, m. $98-9^\circ$, $[\alpha]_D$ -61.5° in alc., -68.7° in C_6H_6 . In the prepn. of *l*-O-menthylxanthogenamide (**II**) and its homologs, the magma of **I** and xylene was neutralized directly with aq. $\text{ClCH}_2\text{CO}_2\text{Na}$, shaken the next day with Et_2O , the middle of the 3 resulting layers again shaken out twice with Et_2O and then treated with concd. NH_4OH ; yield, 8-9 g. crude or about 5 g. pure product from 8 g. menthol. The **II** so obtained m. $147.5-8.5^\circ$, $[\alpha]_D$ -112.5° in alc., -120.1° in C_6H_6 . H_2O_2 with **II** under various conditions gives chiefly **S** or H_2SO_4 and a *compd.* $\text{C}_{22}\text{H}_{38}\text{O}_5\text{N}_2\text{S}$ (**III**); e. g. 6 g. **II** in 50 cc. AcOH with 5 cc. of 30% aq. H_2O_2 gave 0.3 g. *l*-menthylurethan, m. $165-6^\circ$, $[\alpha]_D$ -81.4° in alc., -85.2° in CHCl_3 , and 2.5 g. **III**, m. $105-6^\circ$, $[\alpha]_D$ -134.4° in C_6H_6 (the same *compd.* has been obtained from EtOCSNH_2 and H_2O_2 ; cf. also Debus, *Ann.* 82, 277 (1852)). With 3 mols. $\text{BrCH}_2\text{CO}_2\text{H}$ in C_6H_6 at 40° , 33 g. **II** gave 15 g. $\text{HO}_2\text{CCH}(\text{OC-SNH}_2)$ (**IV**), m. 139° (gas evolution), and 16 g. of a menthyl bromide (Br , 35.86%), b_{15} $103-5^\circ$, d_4^{20} 1.160, n_D^{20} 1.4855, $[\alpha]_D^{20}$ 23.3° ; in another expt from 43 g. **II** and 1.25 mols. $\text{BrCH}_2\text{CO}_2\text{H}$ were obtained 21 g. **IV** and 13 g. of a product with 35.71% Br , b_{11} $97-8^\circ$, d_4^{20} 1.161, n_D^{20} 1.4845, $[\alpha]_D^{20}$ 30.5° . *N*-Me homolog of **II** (*l*-O-menthyl-*N* methylthionurethan) (9-10 g. crude or about 3 g. pure product from 8 g. menthol), m. $91-2^\circ$, $[\alpha]_D$ -106.0° in alc., -114.1° in C_6H_6 , gives with $\text{BrCH}_2\text{CO}_2\text{H}$ *N*-methylamidocarbothiolglycolic anhydride, m. $40.5-1.5^\circ$, and a product with 34.82% Br , b_{10} 96.7° , d_4^{20} 1.168, n_D^{20} 1.4856, $[\alpha]_D^{20}$ 22.7° . *N*-Di-Me homolog of **II** (9-10 g. from 8 g. menthol), m. $26.5-7.0^\circ$, $[\alpha]_D$ -107.7° in alc., -106.2° in C_6H_6 , gives with $\text{BrCH}_2\text{CO}_2\text{H}$ $\text{HO}_2\text{CCH}_2\text{OCSN-Me}_2$, m. $93.5-4.5^\circ$, and a product with 36.50% Br , b_{20} 111° , d_4^{20} 1.1666, n_D^{20} 1.4848, $[\alpha]_D^{20}$ 26.7° . C. A. R.

Constitution of thiourea and the thionium salts. II. HANS LECHER, FRITZ GRAF, CLAUS HEUCK, KARL KÜBERLE, FRITZ GNADINGER AND FRITZ HEYDWEILLER. *Ann.* 445, 35-61 (1925); cf. C. A. 18, 3359. — The theoretical discussion indicates that the sulfonium (**I**) and carbonium (**II**) formulations of thionium salts, while not exptly. disproved, are improbable. The immonium (**III**) formula in its rigid form is exptly. disproved. It is very probable that the basic function is divided between the 2 N atoms. The following oscillation formula is proposed for the thionium ion:

CS(NMe₂)₂ in AcOH-HClO₄, treated with Br in ¹AcOH, gives the *dehydro-bis*-[N,N,N',-N'-tetramethylthiuronium perchlorate], does not m. 220° and explodes harmlessly on heating on a spatula. Me₂NC(:S)Cl does not react with Me₃N. *S-Et N-methylamino-dithioformate*, b₃ 103-4°, m. 30-2° (cf. Delépine, *Bull. chim. soc.* [3], **27**, 813(1902)). (MeS)₂C.S and MeI give only Me₂SI. Carbo-bis[methylimide], MeN·C:NMe, could not be purified because of its great tendency to polymerize; in Et₂O soln. picric acid gives N,N'-dimethyl-N-picrylurea, yellow, m. 169° (decompn.). Carbo-bis[propyl-imide], b₁₀ 53°; the elec. conds of M and 0.1 M solns in 50% EtOH are given; definite salts with mineral acids were not obtained, MeI does not add; picric acid in Et₂O gives a cinnabar-red addn compd., m. 166-9° (decompn.), transformed by shaking with concd. HCl into the yellow N,N'-diethyl-N-picrylurea, m. 176-7°. The addn. product in C₆H₆ is deep orange and has a strong yellow-green fluorescence; the picrate in C₆H₆ is pale yellow-green and does not fluoresce. N,N'-Dimethyl-N,N'-diethylthiourea, b₁₂ 124-5° (cor.), in 50% yield from MeEtNH and CSCL₂. N',S-Dimethyl-N-ethyl-N-phenylpseudothiourea, yellow oil, b₄ 118-20°, 92% yield. S-Benzylthiuronium chloride exists in a stable form (IV), m. 172.5-4°, which crystals from EtOH upon seeding, and a metastable form (V), m. 116-8°, pptd. from a satd. soln. by concd. HCl or satd. NaCl soln. or crystal. from abs. EtOH after seeding with V; a melt of the chloride solidifies to the V form; if the melt at 155° is seeded with IV, it solidifies to that form. A satd. soln., pptd. with concd. H₂SO₄ or allowed to crystal. from hot dil. H₂SO₄, gives the bisulfate, sinters 144°, m. 116-7.5°, crystal. from a little H₂O gives the sulfate, m. 181-8° (decompn.). N',N',S-Trimethyl-N-ethyl-N-phenylthiuronium iodide; with TI picrate, it gives the yellow picrate, m. 87-8°. Transformed into the sulfate, it gives the d-α-bromocamphor-π-sulfonate, which showed only the rotation of the bromocamphor-sulfonic acid anion. N',N',S-Trimethyl-N,N'-diethylthiuronium iodide, m. 81.5-3.5°, from MeEtN(MeS)C·NEt and MeI or (MeEtN)₂CS and MeI in Et₂O; the picrate yellow, b. 52.5-3.5°. III. H. LECHER AND FRITZ HEYDWELIER *Ibid* 77-82.—Me₃N and MeSCN give Me₄NSCN, which is unchanged after heating 3 hrs at 180.5°. MeNCS and Me₃N do not react at room temp. but at 100-10° also give Me₄NSCN. MeNCS is unchanged after heating under the same conditions. C. J. WEST

Some properties of phenylhydrazine and factors affecting hydrazone formation. E. G. R. ARDAGH AND J. G. WILLIAMS. *J. Am. Chem. Soc.* **47**, 2976-83(1925).—This work was preliminary to the evolution of a general iodometric method for the detn. of the CO group content in org. compds. The reaction between PhNHNH₂ and I does not proceed normally in the presence of buffer solns. When a buffer is present, sufficient HCl or H₂SO₄ should be added to render the soln. just acid to Me orange. Solns. of PhNHNH₂ and its salts, especially the acetate, are fairly rapidly oxidized by exposure to air, even at room temp. They are stable in an atm. of N₂. Contrary to the general assumption, a very small change in the Sørensen value of the soln. may very considerably affect the equil. in hydrazone formation. I soln. rapidly attacks hydrazones, hence von Meyer's method (*J. prakt. Chem.* **36**, 115(1887)) is of little value. Petrenko-Kritschenko does not appear to have appreciated the speed of this reaction (*Ann.* **341**, 150(1905)). Defects in the standard Fehling soln. method for the detn. of the CO group are pointed out. Me₂CO phenylhydrazone formation can be forced almost to completion by adjusting the final Sørensen value of the soln. to between 5 and 7, and at the same time salting out the hydrazone. If the hydrazone is now extd. by a selective solvent, immiscible with H₂O, the reaction can be made practically quant. Also in *Trans. Roy. Soc. Can.*, Sec. III, (3) **19**, 75(1925) C. J. WEST

Peralkylated guanidines. III. HANS LECHER, FRITZ GRAF AND FRITZ GNADINGER. *Ann.* **445**, 61-77(1925); cf. *C. A.* **18**, 3359.—N,N',S-Trimethylpseudothiourea, b₁₄ 90°, m. 53-4.5°, in 95% yield from (MeNH)₂CS and Me₂SO₄. N,N',S-Tri-methyl-N-ethylpseudothiourea (I), b₁₅ 79-80° (90% yield). N,S-Dimethyl-N,N'-diethylpseudothiourea, b₁₃ 80° (cor.) (90% yield). N,N',N'',N'''-Tetramethyl-N-ethylguanidine, b₁₃ 61.5-3° (cor.), from I and Et₂NH. N,N,N',N''-Trimethyl-N,N'-diethylguanidine (II), b₁₅ 71-2°. N,N',N'',N'''-Trimethyl-N,N'-diethylguanidine, (III), b₁₂ 68-9° (cor.) N,N'-Dimethyl-N,N'',N'''-triethylguanidine (IV), b₁₂ 80-1° (60% yield). Hexamethylguanidonium picrate, yellow, m. 120-1°; this gives a mol. compd. with picric acid, dark yellow, m. 68.5-71.5°, with Na picrate, yellow, m. 165-6.5°; with sym-trinitrobenzene, yellow, m. 73.5-5°. Chloroplatinate, dark yellow, m. 181.5-2° (cor.). Attempts to prep. an ethylate failed. Pentamethylethylguanidonium picrate, yellow, m. 96-9°. II and EtI, III and EtI and IV and MeI all give the same N,N,N',N''-triethyl-N,N'',N'''-triethylguanidonium iodide, very hygroscopic, does not m. 230°; the triiodide, dark, m. 50-4° to a red liquid; picrate, m. 41.5-4.5°; chloroplatinate, m. 186.5-8.5°. C. J. WEST

Action of benzoic and anisic acids on thiophenols. A. BISTRZYCKI AND J. RISI. *Helvetica Chim. Acta* **8**, 582-91 (1925).—B. and Kuba (C. A. **16**, 711) showed that $\text{Ph}_2\text{C}(\text{OH})\text{CO}_2\text{H}$ (I) and ArSR formed compds. of the type $\text{Ph}_2\text{C}(\text{CO}_2\text{H})\text{C}_6\text{H}_4\text{SR}$, while I and PhSH (II) gave Ph_2S or, in HOAc at 40–5° on cautious addn. of H_2SO_4 , a product which is now shown to be α -phenylmercaptodiphenylacetic acid (III), $\text{Ph}_2\text{C}(\text{CO}_2\text{H})\text{SPh}$, rhombs with 1 H_2O , m. anhyd. 126–8°, mol wt. 321, also obtained by boiling $\text{Ph}_2\text{Cl}-\text{CCO}_2\text{H}$ and II in PhH; Na salt, sparingly sol. in H_2O , m. 205°; Ba salt. III yields only 3.4% CO when treated according to B. and v. Siemiradzki (Ber **39**, 53 (1906)); boiled with $\text{C}_2\text{H}_5\text{N}$, however, it gives *S*-benzohydrylthiophenol, softens 76°, m. 78.5°. Attempts to prep. an anhydride directly or to oxidize III to the sulfone failed, but when boiled with POCl_3 and PCl_5 it gave the chloride, m. 15–50°, converted into 2,2-diphenyl-3-oxothionaphthene-2,3-dihydrate, $\text{C}_{14}\text{H}_8\text{CO CPh}_2\text{S}$, m. 145–6°, by slowly heating to

110°, then quickly to 150°. α -1-Tolylmercaptodiphenylacetic acid, sinters above 135°, m. 155°, behaves like III. α -Phenylmercapto-di-*p*-anisylacetic acid IV, decomps. 106–7°, gives a violet color with H_2SO_4 ; Ba salt. Heated with $\text{C}_2\text{H}_5\text{N}$, or alone at 130–40°, IV gives 4,4'-dimethoxybenzohydrylthiophenol, $(\text{MeOC}_6\text{H}_4)_2\text{CHSPh}$, m. 50.5–1.5°, gives a rose-orange color with H_2SO_4 . $\text{PhCH}(\text{OH})\text{CO}_2\text{H}$ and $\text{Me}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$ failed to react as did I, as did also the α - and β -halogen acids tested. M. H.

Splitting off of diazoanisole sulfate in the complete synthesis of vanillin. E. AZARETTI. *Profumi italiani* **2**, 279–81 (1924), *Chimie et industrie* **14**, 429 (1925).—Guaiacol is prepd. by Fournau's method from *o*-anisidine by decompn. of its diazonium sulfate in presence of CuSO_4 . If proper precautions are taken, a 72–3% yield can be obtained. A flask with a short, wide neck should be used so that the guaiacol formed may be removed by the steam as soon as formed. It is not necessary to pass steam from a sep. generator, that produced from the diazo soln. being sufficient. This soln. should be added drop by drop at such a rate that the vol. and temp. of the catalyzer remain const. The small quantity of guaiacol remaining at the end can be recovered either by raising the temp. to 105° or by passing a current of superheated steam.

A. PAPINEAU-COUTURE

Report (No. 83) of the most important work appearing in the first half of 1925 on the pure chemistry of the sugars. E. O. VON LIPPMANN. *Deut. Zukerind.* **50**, 1173–5, 1205–6, 1237–8, 1278–9 (1925); cf. C. A. **19**, 3028.

W. L. BADGER

Tautomerism in phloroglucinol derivatives. Monomethyl derivatives of phloracetophenone. ADOLF SONN AND WOLFGANG BÜLOW. *Ber.* **58B**, 1691–8 (1925).—3,5-(HO) $_2$ C $_6$ H $_3$ OMe with MeCN gives a *mono Me ether* (I) of phloracetophenone (II), which condenses smoothly with *p*-MeOC $_6$ H $_4$ CHO in alk. soln. to the chalcone MeO(HO) $_2$ -C $_6$ H $_2$ COCH=CHC $_6$ H $_4$ OMe (III); I is provisionally assigned the benzenoid structure 6,2,4-MeO(HO) $_2$ C $_6$ H $_2$ Ac. Solid I allowed to stand 1–2 days with 1 mol $\text{C}_2\text{H}_5\text{N}_2$ in Et $_2$ O gives an *isomer* (IV) of I which is converted by excess of CH_3N_2 into the di-Me ether and does not condense with aldehydes; this is provisionally assigned the structure CH=C(OH)—CHAc. This would indicate that II has the ketodienol structure corre-

sponding to IV, a view in harmony with its behavior on acetylation. Attempts under the most varied conditions to introduce only one CO_2Me group into II with 1 mol ClCO_2Me in aq. alk. soln. gave only very small amts. of the *mono-OCO $_2$ Me deriv.* (V); besides the *di-OCO $_2$ Me deriv.* (VI) there was obtained unchanged II; on the other hand, in anhyd. solvents in the presence of PhNMe_2 II gives the *tri-OCO $_2$ Me deriv.* (VII). A similar behavior is observed in the partial sapon. of the OCO_2Me derivs., VII with exactly 2 or VI with 1 mol. *N* NaOH does not give V but a mixt. of II and VI. Again, II shaken with 1 mol. BzCl in aq. alk. soln. gives chiefly the di- with only a small amt. of the mono-Bz deriv. I (4.5 g. from 5 g. (HO) $_2$ C $_6$ H $_3$ OMe), m. 205–7°, gives a red-violet color with FeCl_3 in H_2O or alc., dissolves in concd. H_2SO_4 with intense yellow color. 4-Methoxy-2',4'-dihydroxy-6'(?)-methoxychalcone (naringenin 4,6(?)-di-Me ether) (III), brownish yellow, m. 169°, gives a brown-red color with FeCl_3 in alc. and dissolves in H_2SO_4 with red color. IV, m. 136–7°, gives a dark red color with FeCl_3 in alc., dissolves in H_2SO_4 with intense yellow color, is much more stable towards alkalis than II. From 5 g. II in 27 cc. *N* NaOH shaken with 3 cc. ClCO_2Me is obtained 6.5 g. VI, m. 114–5°, gives a red color with FeCl_3 in alc., hydrolyzed by shaking in Et $_2$ O with 2 *N* NaOH to I. V, m. 152°, the best yield ever obtained was not over 10%. VII (50% from II and 7 mols. ClCO_2Me in C $_6$ H $_6$ with PhNMe_2), m. 65°, slowly sol. in excess of cold dil. alkali, more rapidly on warming (with hydrolysis of the OCO_2Me groups), gives no color with alc. FeCl_3 . Dibenzoate of II, m. 109–10°. Monobenzoate, m. 177–

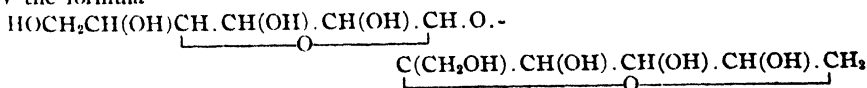

8°. Both Bz derivs. give a red-violet color with FeCl_3 and are hydrolyzed by cold dil. alkali, in which they are easily sol. *Triacetate* of II (3.1 g. from 3.4 g. II with AcCl in $\text{C}_6\text{H}_5\text{-PhNMe}_2$), m. 90°, gives a dark red color with alc. FeCl_3 , slowly dissolves in dil. alkali with yellow color and hydrolysis of the Ac groups. *2,4,6-Trinitroacetophenone*, from $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{CHO}$ and CH_2N_2 in Et_2O , m. 90–2° (decompn.); *phenylhydrazone*, red, m. 193–4°. *p-Carbomethoxybenzaldehyde*, from $\text{HOC}_6\text{H}_4\text{CHO}$ and ClCO_2Me in NaOH , m. 41–2° (Rosenmund, *C. A.* 12, 2569, gives 18.5°). C. A. R.

Synthesis of 2,3,5(or 2,3,4)-trimethylglucose. J. C. IRVINE AND J. W. H. OLDHAM. *J. Chem. Soc.* 127, 2729–35(1925).—Triacetyldibromoglucose results in 50% yields from the glucosan and PBr_5 ; $[\alpha]_D$ 189.9° (c 1.537 in CHCl_3); 185.9° (c 1.256 in glacial AcOH). Triacetylmethylglucoside bromohydrin, $[\alpha]_D$ –1.4° (c 3.012 in CHCl_3); –3.1° (c 3.014 in MeOH); –2.7° (c 3.006 in glacial AcOH). Hydrolysis gives Me glucoside bromohydrin, m. 153–4° (Fischer gives 148°); its *tri-Bz deriv.*, m. 160–2°, $[\alpha]_D$ –5.0° (c 2.413 in CHCl_3). MeI with Ag_2O , after 4 treatments, gave a product b_1 140°, n_D 1.4720, $[\alpha]_D$ –20.5° (c 1 in MeOH); this apparently contained about 20% of dimethylanhydromethylglucoside; extn. of the Et_2O soln. with H_2O finally removed this, giving *trimethylmethylglucoside bromohydrin*, m. 24°, n_D 1.4735, $[\alpha]_D$ –5.8° (c 3.851 in Me_2CO); –4.7° (MeOH); –7.7° (C_6H_6); –3.5° (CHCl_3). A 3% soln. in MeOH , heated with excess of AcOK at 150° for 3 days, gives 72% of trimethyl- β -methylglucoside, m. 93–4°, identical with the 2,3,5-Me₃ deriv. *Trimethylmethylglucoside iodohydrin*, m. 31–4° (it could not be crystd. because of its great soly.), n_D 1.4992, $[\alpha]_D$ 8.6° (c 3.637 in CHCl_3); 4.1° (c 3.897 in Me_2CO); 6.5° (c 4.221 in MeOH). Dry AgNO_2 at 100° for 2 days gives the corresponding NO_2 deriv., n_D 1.4603, which gives a bright red soln. with NaNO_2 and dil. H_2SO_4 , similar to that with MeNO_2 ; this indicates that the vacant HO group is primary. This work indicates that dibromotriacetylglucose, maltose and glucosan are all convertible into the same form of trimethylglucose. C. J. WEST

Glycerol glucoside. HELEN SIMPSON GILCHRIST AND C. B. PURVES. *J. Chem. Soc.* 127, 2735–45(1925); cf. Fischer, *Ber.* 27, 2843(1894).—Glycerol glucoside is best prepd. by heating a 5% soln. of 20 g. glucose in anhyd. glycerol contg. 0.25% HCl in a sealed tube at 100° until it no longer reduces Fehling soln. Me_2SO_4 and NaOH give the *hexa-Me deriv.*, b_{12} 190–2°, n_D 1.4497, which, upon hydrolysis, yields 2,3,5,6-tetramethylglucose, m. 88°, and $\text{HOCH}_2\text{CH}(\text{OMe})\text{CH}_2\text{OMe}$; this established the constitution of the condensation product. The optical values detd. show that γ -glucosides were present only in small amts., the limits in different preps. being 1.95 and 0.93%. The condensation of glucose and $\text{C}_3\text{H}_5(\text{OH})_3$ was followed polarimetrically; the concn. of the HCl varied from 1 to 3%; the results are given as tables and curves; the min. rotation does not appear to depend on the amt. of HCl present. The reaction product in all cases was the above glucoside. On long standing the optical activity of an acid soln. of glucose in $\text{C}_3\text{H}_5(\text{OH})_3$ reverts approx. to its original value, apparently because the condensation is reversed as a result of secondary reactions between the solvent and the acid. The condensation of glucose in the presence of fructose also was studied; under the conditions employed, the behavior of glucose is not affected by the presence of fructose. α,β -Dimethylglycerol (I), b_{15} 69.5–70.5°, n_D 1.4219, d_4^{15} 1.016, $[\text{R}_L]_D$ 30.02 (calcd., 30.1); the rotation of Et tartrate in this compd. is 11.22° (c 13.37); of nicotine, –152.94° (c 13.46); γ -Bz deriv., b_{12} 162°, n_D 1.5075; the *malate* b_{15} 200°, $[\alpha]_D^{15}$ –10.6° (c 9.05 in CHCl_3). The product obtained from MeONa and $\text{HOCH}(\text{CH}_2\text{Cl})_2$ is identical with I. MeI and Ag_2O give β -methyl- α,γ -dichlorohydrin, b_{14} 58°, n_D 1.4560. Hydrolysis with AcOK in EtOH gave the α -, not the β -methylglycerol. *Trimethylglycerol* (II), $b_{765.4}$ 148°, n_D^{15} 1.4069, d_4^{15} 0.9401, $[\text{R}_L]_D$ 35.06 (calcd., 34.84); the rotatory power of Et tartrate was $[\alpha]_D^{15}$ 5.99 (c 13.36). A mixt. of H_2O and II boils const. at 92°. C. J. WEST

Reduction of cinnamaldehyde to cinnamic alcohol in the presence of platinum oxide-platinum black and promoters. XI. W. F. TULEY AND ROGER ADAMS. *J. Am. Chem. Soc.* 47, 3061–8(1925); cf. C. A. 19, 2196.— PhCH:CHCHO cannot be reduced completely with H and PtO-Pt black unless the catalyst is reactivated frequently with air. In the presence of small amts. of Zn or Fe salts the reduction goes completely to $\text{PhCH}_2\text{CH}_2\text{CH}_2\text{OH}$ without the necessity of reactivation. When Fe salt is used and the reduction is stopped after 1 mol. equiv. of H has been absorbed the product is almost pure $\text{PhCH:CHCH}_2\text{OH}$. In the presence of both Zn and Fe salts in the proper proportions PhCH:CHCHO is reduced to pure $\text{PhCH:CHCH}_2\text{OH}$ and no more than 1 mol. equiv. of H is absorbed. The effects of temp. and character of the catalyst are discussed. C. J. WEST

Cleavage of γ -methyl fructoside by saccharases. Configuration of cane sugar. H. H. SCHLUBACH AND GERTRUD RAUCHALLES. *Ber.* 58B, 1842-50(1925).—Since Fischer's Me fructoside and Hudson and Braun's β -Me fructoside, which is undoubtedly derived from the normal stable form of glucose, are not hydrolyzed by invertin, then, if it be assumed that the point of attack of yeast saccharases is on the fructose part of the mol., it would seem probable that these enzymes have a special affinity for Haworth's highly labile γ -fructose and that if a cleavage of Me fructosides by invertin is at all possible this action should best be shown with γ -Me fructoside (I) and this proved to be the case. The mixt. consisting chiefly of the stereoisomeric forms of I obtained by Menzies' method (*C. A.* 17, 70) is hydrolyzed to a certain extent, and only to this extent, by yeast invertin just as rapidly as sucrose. It is proposed to designate the γ -sugars, which are structural, not stereoisomers of the α - and β -forms, as hetero- or h -sugars. When h -I is treated at 30° with a yeast invertin having a time value of 0.26, the rotation decreases in 35 min. from 19.38° to 6.90° and the reducing value increases from 2% to 35%; there is no further change for 7 days, when there begin a further very slow decrease in rotation and increase in reducing power. Since, according to Hudson, the fructose set free almost instantly reaches the equil. value, -90.9° , of normal fructose, the part split off must also have been l -rotatory, hence the more strongly l -rotatory part of the mixt. of stereoisomers, or, in accordance with Hudson, the β - h -I. Yeast saccharase should, therefore, be called a β - h -fructosaccharase. $[\alpha]_D$ for the β - h -I comes out -17° , that of the unhydrolyzed part 36.36° . The latter, however, is not pure α - h -I, for it also contains the unhydrolyzed portion of the normal Me fructoside mixt. present in the original material. The rotation of the reducing equil. mixt. of tetramethyl- h -fructoses from inulin is 32.9° and that of the tetra-Me compd. obtained from Menzies' mixt. of the I (rotation 26.6°) is 24.69° ; this decrease in rotation can be due only to the presence of normal tetramethylfructose (rotation -123.2°); M.'s mixt. must, therefore, contain at least 6.7% of the normal Me fructoside mixt., which must also remain in the portion not hydrolyzed by the invertin; i. e., the rotation of the pure α - h -I must be considerably higher than 36.36° . This is confirmed by the fact that after sepn. from the liberated fructose by extn. with AcOEt the rotation of the unhydrolyzed portion is considerably higher (35.53°) than that of the original material (19.38°). Since in the hydrolysis of the β - h -I by invertin the β - h -fructose liberated must have a higher rotation than the I, then, if its isomerization to the equil. mixt. of normal fructose proceeds appreciably more slowly than its liberation by the invertin, there should be a primary increase in rotation. Hardly any indication of an increase in rotation during the 1st few min. was observed, however, in a hydrolysis expt. at 0° . It required 8 times as long for the reducing power to reach the same value as at 30° . The initial rotation was 24.67° , final 8.5° , when that of the α -form is calcd. to be 39.1° , β -form -14.5° ; from the final product AcOEt seems to ext. chiefly the α - h -I, the residue obtained on evapg the AcOEt showing $[\alpha]_D$ 53.15° . Fischer's Me fructoside, with an initial reduction value of 30%, showed an increase of 12% after 0.5 hr. treatment with invertin, and then remained const., indicating that more than $1/4$ of the Me fructosides has been hydrolyzed or, assuming that β - h -II: α - h -II = 1:2, that the original F' mixt. contained 50% of h -Me fructosides. Taka-saccharase also hydrolyzes I just as smoothly as sucrose and to an even greater extent (69%) than does yeast saccharase, probably because the former also contains an enzyme which attacks the α - h -I; the residue, $[\alpha]_D$ 53.15° , which was not hydrolyzed by yeast-invertin at 0° , was hydrolyzed 30% further by the Taka-enzyme. There is, therefore, no ground for assuming any difference between α - and β -glucosidases on the one hand and the saccharases from yeast and *Aspergillus oryzae* on the other. The results of this work indicate that the fructose, $[\alpha]_D$ 17° , present in cane sugar is β - h -fructose, and that the configuration of cane sugar is best represented by the formula

C. A. R.

Steric series. VI. Configuration of mandelic acid. KARL FREUDENBERG AND LAURA MARKERT. *Ber.* 58B, 1753-60(1925); cf *C. A.* 19, 1407.—From the fact that the rotations of the mandelic acid (I) from amygdalin and of its hexahydro deriv. (II) are lifted towards the right when the acids are converted into the amides, as with the d -HIO acids ((+)-tartaric, (+)-malic, (-)-lactic, (-)-glyceric) it was concluded (*C. A.* 16, 3871) that I is the d (-)-acid. The measurements on which this conclusion was based had been made in dil. aq. or MeOH soln., but in view of the later observation

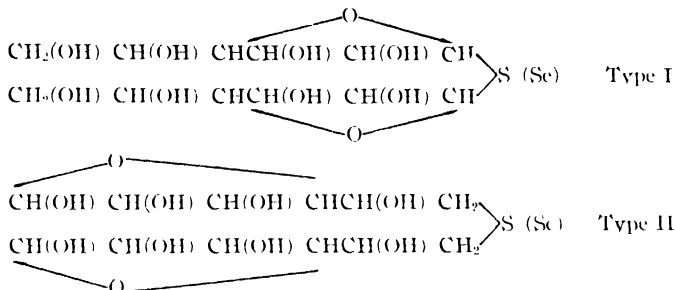

(C. A. 19, 243) that such comparisons of optical consts. are unreliable if the influence of the solvent has not been excluded, the following new measurements, which completely confirm the earlier deductions, have been made. Below are given, resp., the solvent, concn., temp., $[\alpha]$ for the lines 637, 578, 546 and 434, and $[M]_{578}$. Me ester (III) of I: $(\text{CHCl}_3)_2$, 1.08, 20°, —131.8, —172.0, —199.2, —351.9, —285; $(\text{CHCl}_3)_2$, 5.46, 20°, —130.8, —170.0, —200.0, —365.8, —282; $(\text{CHCl}_3)_2$, 15.54, 18°, —136.2, —176.4, —203.4, —377.8, —293; $(\text{CHCl}_3)_2$, 40.41, 20°, —136.2, —176.4, —203.2, —, —293. Et ester (IV) of I: superfused, —, 22°, —100.8, —130.1, —149.8, —277.5, —234. Me acetyl-d(-)-mandelate (V): superfused, —, 20°, —122.2, —155.7, —179.3, —330.4, —324. Et ester (VI): superfused, —, 20°, —97.3, —126.0, —145.3, —268.7, —280. Me benzoyl-d(-)-mandelate (VII): superfused, —, 20°, —124.8, —159.9, —184.3, —339.0, —433. Et ester (VIII): superfused, —, 20°, —109.7, —142.2, —164.2, —303.6, —404. Me hydrocinnamyl-d(-)-mandelate (IX). $(\text{CHCl}_3)_2$, 1.04, 20°, —67.8, —85.6, —98.3, —172.3, —254; $(\text{CHCl}_3)_2$, 4.89, 18°, —70.3, —91.2, —105, —192, —272; $(\text{CHCl}_3)_2$, 19.59, 22°, —73.1, —94.5, —112, —, —282; $(\text{CHCl}_3)_2$, 38.26, 18°, —80.1, —103.8, —120.3, —, —310; superfused, —, 22°, —84.4, —110.8, —127.4, —, —330. Et ester (X): superfused, —, 20°, —68.0, —89.4, —103.2, —, —279. d(-)-Mandelamide (XI): Me_2CO , 5.04, 18°, —59.4, —74.0, —84.2, —140.2, —112; Me_2CO , 12.62, 18°, —61.5, —76.0, —87.1, —115.8, —115, $\text{C}_6\text{H}_5\text{N}-\text{AcOH}$ (1:1), 4.96, 18°, —76.7, —95.5, —107.4, —, —144; $\text{C}_6\text{H}_5\text{N}-\text{AcOH}$, 14.61, 18°, —73.0, —91.6, —104.4, —, —139; $\text{C}_6\text{H}_5\text{N}-\text{AcOH}$, 24.22, 18°, —72.3, —90.7, —103.7, —, —137. d(-)-Hexahydromandelic acid (XII): AcOH , 1.98, 18°, —19.0, —24.7, —27.5, —47.6, —39.0; AcOH , 11.20, 18°, —19.2, —24.6, —28.6, —52.9, —38.9, EtOH , 9.48, 18°, —9.5, —11.2, —13.7, —26.1, —17.7; EtOH , 18.85, 18°, —10.5, —13.2, —15.4, —29.8, —20.8; EtOH , 29.18, 18°, —11.6, —14.5, —16.9, —31.5, —22.9; EtOH , 39.22, 18°, —13.0, —16.3, —18.8, —32.5, —25.7; CHCl_3 , 0.96, 14°, —18.9, —28.0, —34.3, —56.1, —44.3 (extrapolated, —40.4). Me ester (XIII): extrapolated, —, 20°, —19.2, —24.3, —28.3, —53.1, —41.9; extrapolated, —, 12°, —19.9, —24.8, —28.8, —54.1, —42.7. Me acetyl-d(-)-hexahydromandelate (XIV): extrapolated, —, 20°, 11.6, 13.8, 15.3, 21.1, 29.7. Me benzoyl-d(-)-hexahydromandelate (XV): extrapolated, —, 20°, —10.2, —14.0, —17.1, —38.5, —38.6. Me hydrocinnamyl-d(-)-hexahydromandelate (XVI): extrapolated, —, 20°, 8.0, 9.4, 10.2, 13.8, 28.5. Me p-toluenesulfonyl-d(-)-hexahydromandelate (XVII): extrapolated, —, 20°, 21.2, 27.5, 31.2, 52.1, 89.8. d(-)-Hexahydromandelamide (XVIII): EtOH , 5.14, 18°, 39.3, 48.0, 54.3, 81.7, 75.5. Comparison of the values for $(M)_{578}$ (including those previously obtained for d(-)-lactic acid and derivs.) confirms the rule that analogous compds. of the same configuration, subjected to the same changes, undergo a corresponding shifting of their rotations (decrease in l-rotation or shifting towards the right in passing from Me to Et esters, from mandelic to hexahydromandelic derivs., from the acids to the amides). The limitations of this method of detg. configurations are also shown when it is attempted to bring the values for the non-acylated derivs. into line with the others. When the results of Wood and his collaborators (C. A. 17, 1952; 19, 982) on the mol. rotations of d(-)-lactic acid and d(-)-hexahydromandelic esters at 15° and 115° are plotted with $(M)_D$ as ordinates and the mol. wts. of the ester radicals as abscissas, all 4 curves have the same form and in all cases rise in temp. produces a shifting in rotation towards the right. The I, $[\alpha]_{578}^{20}$ —153° (4% H_2O soln.), is obtained in 20 g. yield from 100 g. amygdalin with HCl (d. 1.19) on the H_2O bath. III, m. 58°. IV, b_{16} 137°, m. 34°; yield, 70%. V, from III and Ac_2O in $\text{C}_6\text{H}_5\text{N}$ at 40° (yield, 70%), b_1 100°. VI (yield, 65%), b_1 101°. d(-)-VII, m. 76°. VII, b_2 165°. VIII, b_2 166° (yield, 70%). Me cinnamyl-d-mandelate m. 81°; d-ester, b_2 208° (racemization). dl-Et ester, m. 59°. $\text{PhCH}_2\text{CH}_2\text{COCl}$ (42 g. from 50 g. of the acid with PCl_5 in CHCl_3), b_{16} 112°. dl-IX, m. 65°. IX, m. 34°. dl-X, b_2 282°. X, b_1 172° (yield, 90%). XI, m. 122-3°. XII (its designation by Wood and collaborators as the l-acid is incorrect), m. 129°. XIV, $b_{0.5}$ 87-8° (yield, 80%). XV, $b_{0.5}$ 127-8°, faintly yellow viscous oil (yield, 80%). XVI, $b_{0.5}$ 161-2°, yellowish (yield, 75%). XVII, $b_{0.5}$ 187° (yield, 60%). XVIII, m. 158° (yield, poor). C. A. R.

Derivatives of p-hydroxymethylbenzoic acid. II. Ether esters. F. H. CASE. *J. Am. Chem. Soc.* 47, 3003-5 (1925); cf. C. A. 19, 1417. — $\text{ClCH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ is obtained in 78% yields from p-NCC $\text{C}_6\text{H}_4\text{CH}_2\text{Cl}$ and concd. HCl . Boiling with H_2O until soln. results gives 73% of p- $\text{HOCH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$. p-Bromomethylbenzoic acid, m. 223-4° (73% yield). p-Ethoxymethylbenzoyl chloride, b_8 136-8° (85% yield from the acid and SOCl_2 ; benzyl ester, b_8 198-201° (32% yield); p-carbethoxybenzyl ester, b_8 243-4°, m. 36-7° (58% yield); β -diethylaminoethyl ester, b_8 183-5° (59% yield); HCl salt, m. 122-3°. III. Amino esters. *Ibid.* 3005-8. —Et 4-chloromethyl-3-nitrobenzoate, heavy yellow oil, b_1 170-4°, in 67% yield from 4,3- $\text{ClCH}_2(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{CN}$ and H_2SO_4 in EtOH ; refluxed

with AcONa in EtOH, there results the acetate of *Et 4-hydroxymethyl-3-nitrobenzoate*, yellow, m. 57–8°, from which the Ac group is removed by boiling with HCl-EtOH, giving the *HO deriv.* (I), yellow, m. 115–6° (67% yield); the *benzoate*, pale yellow, m. 129–30°; *phenylurethan*, yellow, m. 125–6° (54% yield). *Et 4-hydroxymethyl-3-aminobenzoate*, m. 85–6° (53% yield by reducing with Sn and HCl or 82% with Pt in dil. AcOH; with PtO and FeCl₃ undesirable by-products were obtained) *HCl salt*, m. 129–30° (decompn.). Reduction of the *Bu deriv.* of I, heavy oil, b₃ 198–203°, gives the *ester* of the *NH₂ deriv.*, m. 76–7°.

C. J. WEST

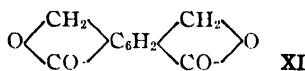

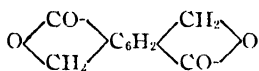

Attempts at synthetic preparation of disaccharides from sugar derivatives containing sulfur and selenium, and their oxidation products. FRITZ WREDE AND WALTER ZIMMERMANN *Z. physiol. Chem.* **148**, 65–82(1925).—Studies were made of 2 types of thio- and seleno disaccharides differing in the location of the S or Se linkage, as follows

In type I (1,1 sulfides or selenides) attempts to replace S or Se by O by treatment with HgO resulted in hydrolysis to the monosaccharide and no *O*-disaccharide could be obtained. In alc soln esterification occurred with formation of β -Et glucoside, and this is proposed as a method for the prepn. of β -glucosides. In a hydrocarbon medium no reaction took place because of the insoly. of the substances, while the Ac derivs. which were sol. underwent oxidation and splitting off of the Ac groups. Thus an exchange of S or Se for O could not be accomplished in the case of 1,1-S or Se sugars or their Ac derivs. Similar expts. with 6,6-S or Se derivs. were likewise unsuccessful. Both 1,1- and 6,6-S derivs., however, can be oxidized to the corresponding sulfones, which are comparatively stable and crystallize readily, but only from the 6,6-Se derivs. could selenoxides be obtained. *Di[tetraacetylglucosyl] 1,1-sulfone* (I), m. 189°, $[\alpha]_D^{20}$ in (CHCl₃)₂ -20.3°, was prepd. by oxidation of di[tetraacetylglucosyl] sulfide in AcOH with KMnO₄ and crystn. from MeOH. *Diglucoyl 1,1-sulfone* ($\frac{1}{2}$ 2H₂O), m. 118°, anhyd., m. 129°, by treatment of I with MeOH satd. with NH₃, evapn. to a sirup and crystn. from dil. EtOH. It is not attacked by yeast or by emulsin. *Di[tetraacetylgalactosyl] 1,1-sulfone* (II), by oxidation of the corresponding sulfide. It occurs in 2 isomeric modifications, m. 175° and 149°, resp. From alc. either form can be obtained at will by seeding with crystals, whereas from C₆H₆ only the 2nd form is obtained. In C₆H₆ $[\alpha]_D^{20}$ = -8.33°, and in MeOH mutarotation from 2.83 to 5.20° was observed in 18 hrs. *Digalactosyl 1,1-sulfone*, m. 182° (gas evolution), $[\alpha]_D^{20}$ -2.10°, was obtained by sapon. of either modification of II with NH₃ in MeOH. *Di[heptaacetylcellosyl] 1,1-sulfone*, sinters 162°, then solidifies and m. 238°, $[\alpha]_D^{20}$ in CHCl₃ -19.9°, was prepd. by oxidation of the sulfide with KMnO₄. *Dicellosyl 1,1-sulfone* (4H₂O), m. above 100° and decomp. 150°, $[\alpha]_D^{20}$ -35.0°. It is not attacked by yeast, but ferments after treatment with emulsin. *Di[triacetylmethylglucosyl] 6,6-sulfone*, m. 232–3°, by oxidation of the corresponding sulfide. *Di[triacetylmethylglucosyl] 6,6-selenoxide*, m. 231°, $[\alpha]_D^{20}$ -18.9°, by similar oxidation of the corresponding selenide. A. W. DOX

Derivatives of cumidinic and pyromellitic acids. H. DE DIETSBACH AND G. ZURBRIGGEN. *Helvetica Chim. Acta* **8**, 546–56(1925).—On passing Br₂ in CO₂ into molten 1,4,2,5-Me₂C₆H₂(CN)₂ and gradually lowering the temp. to 175° until the wt. has doubled there is formed chiefly 1,4-bis[bromomethyl]-2,5-dicyanobenzene (I), m. 163°, and a little 1,4-bis[dibromomethyl]-2,5-dicyanobenzene (II), m. 221°, sepd. by its insoly. in alc., obtained as the chief product if more Br₂ is used. 1,3-Bis[bromomethyl]-4,6-dicyanobenzene (III), m. 114°. All are very irritating, cause eczema, and cryst. with solvent of crystn. 1,4,2,5-Me₂C₆H₂(COCl)₂ below 160° in the same way (cf. Davies, Perkin, and Clayton, *C. A.* **17**, 84) gave the *dibromide* (IV), m. 117–7.5°, of 1,4-bis-

[bromomethyl]benzene-2,5-dicarboxylic acid (V), decomps. 339–40°, from IV and HCO_2H at 85–90°; *di-Et ester* (VI), m. 163–3.5° (decompn.). 1,4-Bis[dibromomethyl]benzene-2,5-dicarboxylic acid (VII), decomps. 259–60°, from the dibromide (VIII), m. 147°, gives off HBr in boiling PhH ; *di-Et ester*, m. 142–2.5°. 1,3-Bis[dibromomethyl]benzene-4,6-dicarboxylic acid, m. 224–5° (decompn.), from the dibromide (IX), m. 104°; *di-Et ester*, m. 93°. In 75% HOAc satd. in the cold with HCl and heated 8–10 hrs. at 180° I gives *p*-pyromellitide (X), decomps. 338–9°, sol. in hot alkalies, also formed from I and boiling

70% H_2SO_4 , or from V in dil. Na_2CO_3 , or from VI. *m*-Pyromellitide (XI), m. and decomps. 277.5–8.5°. X and XI are best recrystd. by dissolving in hot 70% H_2SO_4 and adding a little H_2O . In boiling abs. alc. with dry NH_3 VI yields *p*-pyromellitodiiimidine (X, O = NH), does not m. 350°, insol. in the usual solvents. *m*-Pyromellitodiiimidine, decomps. 340–50°. Pyromellitic dianil, from VI, boiled with PhNH_2 , does not m. 360°. VIII, boiled in H_2O 2–3 hrs. with CaCO_3 slowly deposits, on acidification, 2,5-dicarboxylerephthalaldehyde, m. 257.5–8.5° (decompn.); dioxime, decomps. 153°; bisphenylazone, $\text{C}_{22}\text{H}_{11}\text{O}_2\text{N}_4$, yellow, m. 352°. IX gives 4,6-dicarboxy-*m*-phthalaldehyde, m. 246–7° (decompn.).

M. HEIDELBERGER

Octaethylcellobiose and its acetolysis in comparison with cellobiose and octaacetylcellobiose. KURT HESS AND GÜNTHER SALZMANN. *Ann.* **445**, 111–22(1925); cf. *C. A.* **19**, 3161.—Octaethylcellobiose, $b_{0.5}$ 185–90°, m. 61–6°, results by repeated treatment of heptaethyl- β -ethylcellobioside with Et_2SO_4 ; $[\alpha]_D^{20}$ –2.06° (in CHCl_3); $[\alpha]_D^{22}$ –3.07° (in MeOH). Acetolysis gives a mixt. of the expected triethylacetylglucose and tetraethylacetylglucose, under the same conditions α - and β -octaacetylcellobiose are not attacked, though the β -form is in part transformed into the α -form; cellobiose itself is not split but about 60% acetylated. Hydrolysis gives a mixt. of triethylglucose, identical with that obtained from the acetolysis of ethylcellulose, and tetraethylglucose (2,3,5,6-?), m. 61–4°, $b_{0.5}$ 138–9°, $[\alpha]_D^{20}$ 65.3° (H_2O). β -Benzylcellobioside, m. 187°, $[\alpha]_D^{18}$ –35.46° (H_2O); the *hepta-Me deriv.*, m. 71–2.5°, $[\alpha]_D^{19}$ –32.5° (CHCl_3) (yield, 55%).

C. J. WEST

Influence of phosphorus oxychloride on the catalytic reduction of acid chlorides. F. ZETZSCHE AND OLGA ARND. *Helvetica Chim. Acta* **8**, 591–6(1925).—The initial presence of POCl_3 in p - $\text{C}_6\text{H}_4(\text{COCl})_2$ reduced the yield of aldehyde (detd. as bisphenylhydrazone) on reduction with Pd -kieselguhr in C_8H_{10} at 150° from 64.7% to 11.7%, but did not increase the time of reduction, showing that POCl_3 does not poison the catalyst. It is, however, a contact poison, for if it is gradually vaporized into the reaction mixt. (10 cc. C_8H_{10} , 2 g. BzCl , 0.2 g. catalyst, kept at 105° for 0.5 hr. and then at 140° until evolution of HCl ceases) in a total amt. of over 340 mg. no BzH is formed and the amts. of ester, acid, and non-volatile hydrocarbons formed are increased. The effect of added regulator (cf. Rosenmund and Heise, *C. A.* **15**, 2852) is not entirely abolished. When C_8H_{10} contg. no aldehyde regulator was used, POCl_3 caused a shift toward increased formation of acid and suppression of the volatile hydrocarbons, believed to be due to its reaction with the regulators present and the actual formation of new regulators, rather than a direct action on the catalyst itself. At 200° the effect of added POCl_3 is less. In other reductions, such as of PhNO_2 and $\text{PhCH:CHCO}_2\text{H}$, POCl_3 acts directly on the catalyst, as these substances are recovered unchanged. Quant. data are given and a convention is proposed for expressing the amt. of a regulator in a given sample of solvent.

M. HEIDELBERGER

Chemistry of starch. XIV. H. PRINGSHEIM. Nitric esters of the polyamyloses. J. LEIBOWITZ AND S. H. SILMANN. *Ber.* **58B**, 1889–93(1925); cf. *C. A.* **19**, 2678.—As the evidence advanced by P. for the individuality of β -triarmylose and its identity with β -hexaamylose is apparently not convincing he has undertaken to obtain new data by acylation of the polyamyloses by the Will and Lenze nitration method. The m. ps. and rotations of the various polyamyloses given in the literature have been carefully checked and some new detns. made. The nitration, even with a large excess of the nitrating acid, always gave a mixt. of compds. nitrated to varying degrees; the yield of crude nitrates was always good and they were sepd. into the individual esters by fractionation from alc. or AcOH . On superheating the solns., often even spontaneously, they underwent deep-seated decompn. with evolution of nitrous fumes. α -Tetraamylose octanitrate (I), α -diamylose hexanitrate (II), β -triarmylose hexanitrate (III) and β -triarmylose nonanitrate (IV) were in this way isolated in homogeneous, well-defined form.

and the formation of a *diamylose tetramitate* was proved, although it could not be isolated in pure form. That the two β -compsd. belong to the triamylose series was established by f. p. detns. Both are obtained from the hexa- as well as from the trisaccharide, although triamylose yields relatively more IV. The chief product from α -tetraamylose is I. Sapon. of the nitrates regenerates the original polyamyloses. The α -diamylose was prepd. through the hexaacetate, m. 152° , $[\alpha]_D^{20}$ 106.5° (CHCl_3); the β -hexaamylose, $[\alpha]_D$ 157.1° (H_2O), through the nonaacetate, m. 148° (previously given as 142°), $[\alpha]_D$ 120.4° (CHCl_3); β -triamylose, $[\alpha]_D$ 151.5° (H_2O). I, m. 204° (decompn.), $[\alpha]_D$ 96.4° (PhNO_2), mol. wt. 909-23 (PhNO_2). II, from α -di or α -tetraamylose, m. $206-7^\circ$ (deflagration), $[\alpha]_D$ 79.7° (AcOEt), mol. wt. 573-607 (PhNO_2). III, m. 203° , $[\alpha]_D$ 122.4° (PhNO_2), mol. wt. 782-806 (PhNO_2). IV, m. 198° , $[\alpha]_D$ 90.5° (PhNO_2), mol. wt. 885-948. All the above nitrates gradually become yellow in a desiccator and finally lose up to 75% of their N. C. A. R.

Chemistry of substances of high molecular weight. I. An anhydride of cellobiose. MAX BERGMANN and EWALD KNEHE. *Ann.* **445**, 1-17 (1925).—Cellulose is dissolved in a mixt. of AcCl , AcOH and HCl (prepd. by satg. AcO with HCl); after 2-3 days, the soln. is poured into H_2O , the acetate extd. with CHCl_3 , the product treated with HBr in AcOH , poured into H_2O , extd. with CHCl_3 , the Br removed with AcOAg and the product extd. with MeOH several times, giving *tetraacetylcellobiose anhydride*, sinters 155° , becomes transparent at 165° and m. 185° ; $[\alpha]_D^{20}$ -19.6° ($\text{C}_6\text{H}_5\text{Cl}_4$); mol. wt. in AcOH : concn., 0.31%, 499; 0.59%, 508; 1.27%, 559; 1.85%, 603; 2.50%, 659; 3.10%, 614; calcd., 492; in PhOH , from 535 to 590, with concns. from 0.57 to 2.54% (about 10% too high); in CHBr_3 , 1514 and 1583 at concns. of 0.2 and 0.33%; in molten camphor, 1680 at a concn. of 4.2%. Ac_2O in $\text{C}_6\text{H}_5\text{N}$ gives a *hexa-Ac deriv.*, sinters 178° , m. 229° ; $[\alpha]_D^{19}$ -14.75° ($\text{C}_2\text{H}_5\text{Cl}_4$); mol. wt. in AcOH , 569-631 for concns. from 0.29 to 1.30%; in PhOH , 618 to 692 for concns. from 0.35 to 1.1% (about 15% too high). With Ac_2O , AcOH and H_2SO_4 there results from the tetra-Ac deriv. *octaacetylcellobiose*. Sapon. of the tetra-Ac deriv. with 0.5 N KOH - EtOH gives *cellobiose anhydride*, sinters 200° , decomp. about 285° . It is sol. in dil. alkali, from which it is pptd. by AcOH . Fehling soln. is strongly reduced in the hot but not alk. I solns. It is easily sol. in NH_4OH - CuO , from which it is pptd. by acids or upon diln. Reacetylation gives a mixt. of the 2 acetates. **II. "High molecular" amino acid anhydrides of the piperazine type.** M. BERGMANN, ARTHUR MIEKELEY and ERICH KANN. *Ibid* 17-34.—Glycyl-serine gives rise to 3-methylene-2,5-diketopiperazine, which shows a normal mol. wt. in freezing PhOH ; the 3-methylene-6-methyl 2,5-diketopiperazine (I) from alanyl-serine likewise shows a normal mol. wt. in boiling PhOH as does the iso-compd. (II). The *di-Na compd.* (III) of II ppts. from 20% NaOH and analyzes for $(\text{C}_6\text{H}_6\text{O}_2\text{Na})_2 \cdot 13\text{H}_2\text{O}$; upon drying it still appears to retain $1\text{H}_2\text{O}$. III with Ac_2O in CCl_4 gives the *diacetate* (B) (IV), m. $144-5^\circ$ (cor.), mol. wt. in C_6H_6 , normal. It easily splits off the Ac groups, giving II; with AcOH only 1 Ac is split off, giving a *mono-Ac deriv.* of II, m. 225° . With concd. NH_4OH or dil. HCl this also gives II. I and Ac_2O gives a *diacetate* (A), m. $110-1^\circ$ (cor.). Catalytic reduction of II or IV gives alanine anhydride, m. 282° . Isomethylenediketopiperazine, heated with 5 N HCl 4 days at 70° , gives a *tetrapeptide-HCl*, $\text{C}_{10}\text{H}_{14}\text{N}_4\text{ClO}_6 \cdot \text{HCl}$, does not m. at 300° ; its *Me ester* decomp. 280° . II likewise gives rise to a *compd.* $\text{C}_{13}\text{H}_{21}\text{O}_6\text{N}_4\text{Cl}_2$, sinters 232° , decomp. 238° .

C. J. WEST

Tautomeric phenomena in heterocyclic compounds. GUSTAV HELLER, ARNOLD BUCHWALDT, RUDOLPH FUCHS, WERNER KLEINICKE and JOHANNES KLOSS. *J. prakt. Chem.* **111**, 1-22 (1925).—The Ag salt of phthalimidine and AcCl give the Ac deriv., m. 151° ; BzCl gives a mixt. of a colorless and a light red substance, which could not be sepd. because of change during crystn.; the action of MeI or EtI regenerates the free base, which is not attacked by CH_3N_2 . The Ag salt of saccharin and MeI in Et_2O at 100° give a mixt. of the *N-Me deriv.*, m. $130-1^\circ$, and the *O-Me deriv.*, m. $180-1^\circ$. Similarly, EtI gives a mixt. of the 2 derivs. AcCl gives the *N-Ac deriv.*, m. 193° . BzCl , however, possibly gives a mixt. of the *O*- and *N-Bz derivs.*, the *O-deriv.*, m. $255-7^\circ$, being obtained in very small amts. Saccharin and CH_3N_2 give about 20% *O-Me* and 80% *N-Me* derivs. *o*-Phenyleneurea in dil. NaOH gives a *di-Na salt* (I), but with EtOH - NaOH there results a *mono-Na salt* (II), which dissociates on warming with H_2O . Ag salt, sensitive to the light. I and BzCl give the *N-di-Bz deriv.*, m. $212-3^\circ$; II likewise gives this deriv. besides free urea. The Ag salt and BzCl give the *O-Bz deriv.*, m. 205° . *N-Di-Ac deriv.*, m. 149° , by direct acetylation or from I or II and AcCl . *O-Ac deriv.*, m. 205° , from the Ag salt and AcCl . The K salt of *o*-phthalhydrazide and BzCl give the *O-Bz deriv.*, m. $221-2^\circ$ (90% yield); *O-Ac deriv.*, m. 164.5° . The Ag

salt and MeI give the *O*-Me deriv., m. 187° (50% yield). *O*-Carbethoxy deriv., m. 145°. There is also formed some of the *N*-dicarbethoxy deriv., m. 136°. The Ag salt of phenyloxamide is rather sensitive to light; K salt, glistening leaflets. *O*-Bz deriv., m. 176°, by direct benzoylation; the salts do not react normally with BzCl; an Ac deriv. could not be prepd. The Ag and Na salts of benzoylencurea were prepd. With BzCl this gives some dibenzoylencurea, m. 153-4°, some mono-Bz deriv., m. 206° (decompn.), which yields a cryst. Na salt. Benzoylbenzoylencurea, m. 216-7° (decompn.). Benzoylbencazimide, m. 132-3°. Ac deriv., m. 165° (40% yield). MeI and the Na salt gives only 1 product, m. 123°. Carbethoxy deriv., m. 65-6°; heated with dil. HCl it gives carbonylsalicylamide, m. 224-5°. C. J. WEST

Isolichenin and the degradation of starch. P. KARRER. *Z. physiol. Chem.* **148**, 62-4 (1925).—Polemical. Pringsheim's contention (*C. A.* **19**, 2813) that isolichenin is hydrolyzed by diastase quant into maltose is based upon detns. of reducing power and optical rotation and not upon a quant isolation of any cryst. deriv. of maltose. A 5% yield of mannose phenylhydrazone was obtained by K. from isolichenin prepd. by P.'s method, and a 6% yield from a sample of P.'s own material. P.'s amylobiose and amylotriose might as well be considered reversion-dextrins as hydrolytic products of polyoses, since mixts. with the same properties can be obtained by the action of HCl on maltose. A. W. DOX

Benzene substitution. Different influence of some alkyloxy groups in aldehyde syntheses by means of hydrocyanic acid. ADOLF SONN AND ERICH PASCHKE. *Ber.* **58B**, 1698-703 (1925).—The orienting influence of different alkyloxy groups was studied by subjecting dialkyl ethers of *m*-C₆H₄(OH)₂ with 2 different alkyl groups to the Gattermann aldehyde synthesis (in which the CHO group always enters a *p*-position to one of the alkoxy groups) and detg. by the solidification point method the relative amts. of the 2 isomeric dialkylresorcylic aldehydes formed. To avoid any possibility of splitting off of the alkyl groups by AlCl₃ the condensations were effected in the presence of ZnCl₂ and after decomp. the aldimide HCl salts by short boiling with H₂O the aldehydes were purified through the NaHSO₃ compds.; yield, 50-60%. MeOC₆H₄OH·Et gave 55 parts 2,4- and 45 parts 4,2-MeO(EtO)C₆H₃CHO; MeOC₆H₄OPr yielded about equal parts of the 2 isomers, and MeOC₆H₄OCH₂CH₃ formed about 70 parts 2,4- and 30 parts 4,2-MeO(CH₂CHCH₂O)C₆H₃CHO. The orienting influence, therefore, decreases in the order CH₂CHCH₂O, EtO, PrO, MeO. MeOC₆H₄OCH₂Ph gave about equal parts of the isomeric MeO(PhCH₂O)C₆H₃CHO (total yield, about 40%), together with a mixt. of a little 2,4- with considerable 4,2-HO(MeO)C₆H₃CHO. The pure dialkylresorcylic aldehydes necessary for constructing the solidification-point diagrams were prepd. by alkylating the corresponding mono-Me derivs. whose aldimide HCl salts are obtained by condensation of MeOC₆H₄OH in Et₂O with anhyd. HCN and HCl in the presence of ZnCl₂. *Resorcinol Me benzyl ether* (20 g. from 16 g. MeOC₆H₄OH with PhCH₂Cl and NaOEt), faintly yellow oil, b₁₄ 186°, m. 31-2°. *2-Methoxy-4-ethoxybenzaldehyde* (3.1 g. from 4 g. MeO(HO)C₆H₃CHO with EtBr and NaOEt), m. 58-9°; *4,2-isomer*, m. 64-5°. *O²-Methyl-O⁴-propylresorcylic aldehyde*, prisms with faint aromatic odor, m. 45°; *4,2-isomer*, prisms with a pleasant odor, m. 37°. *O²-Methyl-O⁴-allyl deriv.*, light yellow prisms of characteristic pleasant odor, m. 47-8°; *4,2-isomer*, light yellow, m. 38°. *O²-Methyl-O⁴-benzyl deriv.*, m. 59°; *4,2-isomer*, m. 67°. C. A. R.

Tannins and similar materials. XX. Transformation of cyanidin into catechol. KARL FREUDENBERG, HANS FIKENTSCHER, MAX HARDER AND OTTO SCHMIDT. *Ann.* **444**, 135-45 (1925); cf. *C. A.* **19**, 2041.—*l*-Epicatechol, transformed into the penta-Ac deriv. and then methylated with Me₂SO₄ and KOH (5 times), gives a small yield of the *penta-Me deriv.*, m. 103-4°, α_D¹⁸₇₈ -83° (in C₂H₂Cl₄); the corresponding *d-deriv.*, m. 103-4° and has α_D¹⁸₇₈ 84°; the *dl-deriv.*, m. 113-4°; its *Br deriv.*, m. 138-9°; the same products were obtained by catalytic reduction of cyanidin penta-Me ether, while reduction of cyanidin gives 32% of the free *dl-epicatechol*, decomp. 224°, identified as the penta-Ac deriv., m. 168-9° (cor.). Since cyanidin has been synthesized, this constitutes a synthesis of *dl-epicatechol* and of catechol. C. J. WEST

Preparation of isonuclear bromonitronaphthalenes from the corresponding tetralin derivatives. V. VESELÝ AND L. K. CHUDOŽILOV. *Bull. soc. chim.* **37**, 1436-44 (1925).—See *C. A.* **19**, 3486. H. G.

Catalytic hydrogenation under reduced pressure. RENÉ ESCOURROU. *Chimie et industrie* **14**, 519-29 (1925).—See *C. A.* **19**, 2028. A. PAPINEAU-COUTURE

Δ¹-Dihydronaphthalene. V. The addition of nitrogen oxides and of nitrosyl chloride to Δ¹-dihydronaphthalene. FRITZ STRAUS AND WILLY EKHard. *Ann.* **444**, 146-64 (1925); cf. *C. A.* **15**, 1896.—Δ¹-Dihydronaphthalene (I) (3 g.) in 60 cc. petroleum

ether, treated with the N oxides from 6.5 g. NaNO_2 (liberated by 10% H_2SO_4), gives 2.8 g. of the *pseudonitrosite* (II), decomps. $95-6^\circ$; it is decompd. by warming in soln. and also on standing. Treating II with ice-cold 10% KOH or with piperidine gives the *ac-2-nitro deriv.*, citron-yellow, m. 52° ; reduction with Zn and AcOH gives β -tetralone-oxime, and a small amt. of a compd., m. 206° (decompu.) II, allowed to stand some time, treated with PhNH_2 in boiling EtOH or simply with boiling EtOH, gives *ac-1-oximino-2-nitrotetralin*, m. 136.5° (decomps. 138°), also formed from I and N oxides in AcOH; boiling with 25% H_2SO_4 gives *hydrocinnamic-o-carboxylic acid*, m. $165-6^\circ$. A mixt. of 3 g. I and 3 g. AmNO_2 , treated dropwise with 6 cc. cold fuming HCl, gives 15% of the *bisnitrosochloride*, decomps. $128-9^\circ$ (depends upon rate of heating), heating with piperidine in EtOH gives the *nitrolamine*, $\text{C}_{15}\text{H}_{20}\text{ON}_2$, m. $171-2^\circ$. Indene gives 30% of a *bis-nitrosochloride*, decomps. about 180° ; the *nitrolamine*, $\text{C}_{11}\text{H}_{15}\text{ON}_2$, m. $155-6^\circ$. I and NO_2 give a compd., m. $172-3^\circ$; with MeOH-KOH or with piperidine there results 30–40% of the 2 NO_2 deriv. α -Tetralone (III) and AmNO_2 , treated with EtOK, give a light yellow K salt, which with HCl gives 48.6% of the 2-oximino deriv., m. 140° , decomps. 141° . III and EtNO₂ with EtOK give the K salt of *ac-nitro- α -tetralone*, brownish red, which couples with $\text{HIO}_3\text{SC}_6\text{H}_4\text{N}_2\text{X}$ to give a deep bluish red product; with 15% HCl the salt gives a poor yield of γ -phenyl-o-carboxylic-propylnitrolic acid, decomps. $104-6^\circ$. VI. **Alicyclic 1-hydroxy- α -tetralone and β -naphthohydroquinol; autoxidation of polyhydric phenols.** F. STRAUS, OTTO BERNOLLY AND PAUL MAUTNER. *Ibid* 165-94 —1-Bromo- α -tetralone (IV), m. 40° , is obtained in 92% yields by oxidizing 1-hydroxy-2-bromotetralin or in about 40% yields by bromination of α -tetralone. IV, AcONa and AcOH give 83% of 1-acetoxy- α -tetralone (V), m. $74.5-5^\circ$, b₂₀ 180° (slight decompn.); it reduces Fehling soln. in the cold; shaken with KOH in the air, the light yellow soln. passes through a yellow-brown to a deep dark green and finally to a stable orange-red. By-products are α - and β -naphthol. Warmed with concd. HCl on the H_2O bath, V gives 75% of β - $\text{C}_{10}\text{H}_7\text{OH}$. V, saponid with K_2CO_3 in dil. MeOH in an atm. of H, gives 82% of *ac-1-hydroxy- α -tetralone*, m. $36-6.5^\circ$, b_{0.1} 93° ; it quickly reduces Fehling soln.; in alk. soln. it shows the same color changes as V. PhNHNH_2 gives a deep red product which was not investigated. Concd. HCl gives β - $\text{C}_{10}\text{H}_7\text{OH}$. $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$ readily gives V. IV (0.2353 g.) is completely decompd. by 0.06 g. KOH in MeOH in 0.5 hr. With MeONa, 33% is decompd. in 0.5 hr., 64% in 24 hrs., 100% in 48 hrs. The color changes are described. From the violet soln. α -tetralone may be isolated as the oxime. Ag₂O does not react with IV in Et₂O or in boiling Me₂CO. The Br of IV is also quant. removed by $\text{C}_6\text{H}_5\text{N}$ after 1 hr. Piperidine in MeOH gives *dimol. piperido- α -tetralone* (?), m. $212.5-3^\circ$ (decompu.), mol. wt. in freezing C_6H_6 , 453; it is sol. in dil. HCl; with dil. KOH there results an Et₂O-sol. grass-green product. There is also formed in the above reaction a considerable amt. of α -tetralone. In an atm. of H there is no reaction with piperidine; admission of air quickly causes reaction. β -Naphthohydroquinol (VI), m. $103-4^\circ$; its hydrate, m. $59-60^\circ$. Oxidation with 1 equiv. O gives 3,4,3',4'-tetrahydroxy-1,1'-binaphthyl (VII), m. $205-10^\circ$ (Stenhouse and Grove, *Ann* 194, 208(1878) give $176-8^\circ$) and is identical with the product from the oxidation of binaphthyl quinhydrone (VIII). *Tetraacetate*, softens $137-8^\circ$, m. 165° . *Tetra-MeO deriv.*, b_{0.67} $200-20^\circ$, m. $145-7^\circ$. Oxidation of VI with 1–2 atoms O gives a mixt. of VIII and VII, the amt. of VII decreasing with increasing amts. of O. With excess of O there results naphthalic acid. Oxidation of VII with 1 atom O gives a nearly quant. yield of VIII, sinters 245° , m. $250-2^\circ$, decomps. 255° ; with excess of O, naphthalic acid. Oxidation of *ac-1-hydroxy- α -tetralone* with 1 atom O gives VI, with 1.5 to 3 atoms O, VII and VIII, with excess O, naphthalic acid.

C. J. WEST

"Tervalent" carbon. III. **Pentaphenylcyclopentadienyl.** K. ZIEGLER AND B. SCHNELL. *Ann.* 445, 266–82(1925); cf. *C. A.* 18, 2338.—Desoxybenzoin (I) and HCHO are condensed by KOH in EtOH to give 90% of methylencidesoxybenzoin, which is reduced by Zn dust in AcOH to 2,3,4,5-tetraphenyl-3,4-dihydroxycyclopentane; the moist ppt., boiled with H_2SO_4 in AcOH, gives 60% (based on the I used) of tetraphenylcyclopentadienyl; with *p*-ONC₆H₄NMe₂ this gives 80% of the *p* dimethylanyl, nearly black needles, m. $224-6^\circ$, of 2,3,4,5-tetraphenyl-2,4-cyclopentadien-1-one, black-violet, m. $217-8^\circ$ (30 g. from 100 g. I); hot C_6H_6 hydrocarbons dissolve it with a red color; it distills nearly undecompd. It is easily oxidized by hot AcOH-CrO₃, probably giving 1,3-diphenyltriketopropane and benzil; it is also attacked by hot EtONa. It reacts readily with PhMgBr , giving an equal wt. of 1,2,3,4,5-pentaphenyl-2,4-cyclopentadien-1-ol, m. $175-6^\circ$. HCl passed through the gently boiling AcOH soln. gives nearly quant. the 1-Cl deriv., yellow, m. 167° . 1-Br deriv. (II), orange-yellow, m. $188-9^\circ$; 0.001 mol. in 60 cc. abs. Et₂O, shaken with 30 cc. H_2O at 22° for 1 hr., shows no hydrolysis while

found in the region from 2.7μ to 3.4μ is apparently valid in the case of α - $C_{10}H_7NH_2$ and its derivs. The striking similarity in the absorption spectra of α - and β - $C_{10}H_7NH_2$ renders it very probable that the alkyl- β -naphthylamines follow this same differentiation. The possibility of another region of absorption displaying a similar differentiation has been suggested for the region of 6.2μ .

C. J. WEST

Catalytic dehydration of phenol-alcohol systems. II. Naphthol-alcohol systems. W. PLÜSS. *Helvetica Chim. Acta* **8**, 507-12 (1925); cf. *C. A.* **19**, 2648.—A smaller excess of MeOH was used than in the last paper, and the Al_2O_3 had to be renewed frequently, because of the deposition on it of resins and $C_{10}H_7OH$. $C_{10}H_8$ in MeOH, dropped on Al_2O_3 at 420° , is not changed. With β - $C_{10}H_7OH$ (I) the resulting oil was washed with KOH and distd. *in vacuo*. The portion b_{12} 102 – 50° deposited the $C_{10}H_7Me_4$ (II) already described, the residue consisting of tri-Me derivs. Sulfonation of this yielded nothing definite, but nitration of 70 g. of the fraction b_{12} 142 – 50° according to Lesser (*C. A.* **8**, 661) in HOAc with concd. HNO_3 gave 26 g. of a *nitrotrimethylnaphthalene*, m. 142 – 3° , also obtained in 15–30% yield from any fraction b_{12} $>135^\circ$; amino derivative, b_{12} 198 – 200° , m. 115 – 6° , sensitive to light; diazotized, it gives a red dye with I, but not with R-salt. Nitration of II yielded nothing definite. Under 40 mm. at 380° I is not attacked and small amts. HCHO are formed. EtOH, BuOH, AmOH give polyalkylated products contg. O. α - $C_{10}H_7OH$ gives no solid hydrocarbons, while PhOI \dot{e} t is unattacked. ZnO and Al dehydrate alics., but do not act on PhOH or I as does Al_2O_3 .

M. HEIDELBERGER

Symmetrical substitution derivatives of trimethylene dibromide and pentamethylene dibromide. Wm. H. MILLS and LESLIE BAINS. *J. Chem. Soc.* **127**, 2502–7 (1925).— β -Phenyl- β -methylpropane- α,γ -diol, b_{17} 184° , m. 88° , from PhMeCHCHO, HCHO and K_2CO_3 ; di-Ac deriv., b_{20} 179° ; heated with AcOH satd. with HBr 30 hrs. at 100° , and the operation repeated with the oil obtained by pouring into H_2O , 200 g. diacetate gave 20.5 g. α,γ -di-Br deriv., b_{12} 143 – 6° . The glycol in AcOH, satd. with HBr for 3 hrs. at 0° , then heated 7 hrs. at 100° (HBr being passed into the soln.), gave the α -bromo- γ -hydroxy deriv., b_{15} 173° . The α -Cl deriv., b_{15} 117 – 8° , results from the glycol and PCl_5 at 80° for 2 hrs. or from the glycol in C_6H_5N and $SOCl_2$. The diacetate in an equal vol. of AcOH, treated with HBr at 90 – 5° for 19 hrs. after the mixt. had become satd., gave the α -bromo- β -acetoxy deriv., b_{18} 174 – 4.5° . α,γ -Dibromo- β -phenylpropane, b_{14} 152° , strong geranium-like odor, from PhCH(CH $_2$ OAc) $_2$ and HBr. (PhOCH $_2$ CH $_2$) $_2$ CHCO $_2$ H, boiled 10–12 hrs. with a mixt. of const. boiling and fuming HBr, the product taken up in EtOH and satd. with HBr, gives Et α,ϵ -dibromopentane- γ -carboxylate, b_{19} 166 – 7° , garlic-like odor; with piperidine in EtOH it gives 4-carbethoxybis-piperidinium-1,1'-spiran bromide, very hygroscopic, analyzed as the picrate, Au-yellow, m. 130° . Hydrolysis with dil. HCl gives 4-carboxybis-piperidinium-1,1'-spiran bromide, yellow, m. 289 – 90° (decompn.), whose picrate, Au-yellow, m. 169 – 70° .

C. J. WEST

Dibenzoylxylenes and the dinaphthanthracenediquinones. III. H. DE DIESBACH and K. STREBEL. *Helvetica Chim. Acta* **8**, 556–66 (1925); cf. *C. A.* **17**, 3028; **18**, 3188.—The method of transforming ketones or diketones of the types α -Me C_6H_4 Bz (I) and 1,4-, 2,5-Me $_2$ C $_6$ H $_2$ Bz $_2$ (II) into anthraquinones by the direct action of Br $_2$ (cf. Thorner and Zincke, *Ber.* **12**, 1479 (1877), who used Cl $_2$) or by the action of Br $_2$ followed by dehydration agents, is only of limited application, being usually accompanied by bromination of the nucleus. In boiling HOAc with gradual elevation of the temp. to 170 – 80° as BrCH $_2$ CO $_2$ H is formed, I and Br $_2$ give a mixt. of $C_6H_4(CO)_2C_6H_4$ (III) and its Br derivs. In PhNO $_2$ 20% of the theory of III is obtained. 2,4'-Dimethylbenzophenone, from α -MeC $_6H_4$ COC(1, PhMe, and AlCl $_3$, yellowish oil, b. 300 – 3° ; brominated as was I in HOAc, followed by oxidation in hot aq. Na $_2$ CO $_3$ with KMnO $_4$ and condensation with H $_2$ SO $_4$ at 160 – 80° for a few min. it gave 3-bromo-anthraquinone-2-carboxylic acid, decomps. above 310° , forms a red vat, boiled with PhNH $_2$ and Cu salts, the Br is not eliminated, indicating its position as given. 2-Methyl-4'-methoxybenzophenone, b. 325 – 30° , yielded 1,4,2-Br $_2$ (HO)C $_6$ H(CO) $_2$ C $_6$ H $_4$. 2-Methyl-3',4'-dimethoxybenzophenone, m. 75° , yielded no definite results with Br $_2$ in HOAc. In PhNO $_2$ II gave 50% of $C_6H_4(CO)_2C_6H_4(CO)_2C_6H_4$ (IV), while in HOAc it yielded a mixt. of acids giving a violet vat and forming IV and a little Br deriv. on condensation. The 2',5',2'',5''-Cl $_4$ deriv. of II in PhNO $_2$ gave a mixt. of acids and quinone converted into a tetra-Cl deriv. of IV on condensation. The 4',4''-Me $_2$ deriv. (V) of II gave a mixt., while the expected 2,5-[4',4''-dicarboxy-dibenzoyl]terephthalic acid was prepd. by heating V with HNO $_3$ (d 1.15) at 200° for 8 hrs., followed by KMnO $_4$ in boiling aq. Na $_2$ CO $_3$; it decomps. above 340° ; Bu salt. In H $_2$ SO $_4$ at 200° for 5 min. it gives dinaphthanthracene-5,7,12,14-diquinone-3,10-dicarboxylic acid (VI), HO $_2$ CC $_6$ H $_3$ (CO) $_2$ C $_6$ H $_2$ (CO) $_2$ C $_6$ H $_3$ CO $_2$ H, does not m. 340° , purified

over the NH_4 salt; the K and Na salts are sparingly sol.; the vat is blue-violet, oxidizing to blue in air. The 4',4''-(MeO)₂ deriv. of II in HOAc gave a *tetrabromo-2,5-[4',4''-dihydroxydibenzoyl]terephthalic acid*, which, in H_2SO_4 at 200° for 5 min., gave the *tetrabromo-2,9-dihydroxydinaphthanthracene-5,7,12,14-diquinone*, does not m. 330° , sol. in alkalis with a red color, gives a green vat. Condensation of 1,4,2,5-Me₂C₆H₂(COCl)₂ with *o*-C₆H₄(OMe)₂ gave 1,4-dimethyl-2,5-[3',3'',4',4''-tetramethoxydibenzoyl]benzene, m 215° . From 1,3,4,6-Me₂C₆H₂(COCl)₂ were obtained the following. With PhMe, 1,3-dimethyl-4,6-[4',4''-dimethyldibenzoyl]benzene, m. 118° ; with PhOMe, the 4',4''-di-MeO analog, m 95° ; and with *o*-C₆H₄(OMe)₂, the 3',3'',4',4''-tetra-MeO analog, m 137° . M. HEIDELBERGER

- **Effect of the position of the radicals on the properties of benzene derivatives.**
I. PASTAK. *Rev. chim. ind.* **34**, 309-12 (1925).—Brief review. A. PAPINEAU-COUTURE

Parachor and chemical constitution. III. Orientation isomerism in aromatic compounds. SAMUEL SUGDEN AND HENRY WILKINS. *J. Chem. Soc.* **127**, 2517-22 (1925); cf. *C. A.* **19**, 3263.—Within the exptl. error, about ± 2 units, there is no appreciable difference between the parachors of *o*-, *m*- and *p*-isomers of the C₆H₄Me₂, O₂NC₆H₄Me, ClC₆H₄NO₂, BrC₆H₄NO₂ and MeC₆H₄CN, the values obtained from the surface tension and d being in good agreement with the theoretical values. This agreement shows that the Kekulé formula will serve to reproduce the exptl. figures, however, in all cases but 2 the observed parachor is lower than the theoretical figure, which may be accounted for by the equil with a bridged structure. The difference in reactivity of the halogen in these compds is not due to differences in the mol. vol. *o*-O₂NC₆H₄Me, ρ_{762} 219.9-5° (cor.); d_4^{25} 1.180-0.00098 t; γ 41.76, 38.69, 36.76, 34.70 at 19.5°, 44.5°, 62.5°, 79.0°. *m*-O₂NC₆H₄Me, m 16° (cor.); d_4^{25} 1.180-0.00095 t, γ 41.36, 38.73, 36.37, 33.45, 30.53 at 20°, 42°, 61°, 91° and 116°. *o*-ClC₆H₄NO₂, m 33° (cor.); d_4^{25} 1.398-0.00110 t; γ 42.29, 39.80, 37.23, 34.04 at 50.5°, 70.5°, 91.5° and 121°. *m*-ClC₆H₄NO₂, m 46° (cor.); d_4^{25} 1.398-0.00111 t; γ 41.79, 38.76, 36.27, 31.77 at 60.5°, 74.5°, 90.5°, and 129°. *o*-BrC₆H₄NO₂, m 39° (cor.); d_4^{25} 1.735-0.00133 t; γ 43.14, 42.12, 40.56 and 38.94 at 55.5°, 67.5°, 80° and 94.5°. *m*-BrC₆H₄NO₂, m 55.5° (cor.); d_4^{25} 1.728-0.00130 t, γ 42.25, 41.36, 40.10, 38.94 at 63°, 71.5°, 83° and 91°. *p*-BrC₆H₄NO₂, m 127° (cor.); d_4^{25} 1.736-0.00130 t; γ 34.58, 33.12, 31.78, 30.63 at 132°, 145°, 159.5° and 170°. *o*-MeC₆H₄CN, b_{759} 205.5-5°, d_4^{25} 1.017-0.00072 t; γ 35.34, 33.33, 30.96, 28.41 at 51°, 69°, 90° and 116.5°. *m*-MeC₆H₄CN, b_{759} 213 (cor.); d_4^{25} 1.003-0.00082 t; γ 38.20, 35.16, 31.14, 30.88 at 18.5°, 47°, 64.5° and 86.5°. *p*-MeC₆H₄CN, m 29° (cor.); d_4^{25} 1.004-0.00078 t; γ 34.32, 32.67, 31.05, 29.84 at 51.5°, 67.5°, 82.5° and 96°. Thiazoles. VII. The behavior of *o*-aminophenyl mercaptan with aldehydes, ketones and gem-dihalides. The synthesis of benzothiazoles. M. T. BOGERT AND ARTHUR STULL. *J. Am. Chem. Soc.* **47**, 3078-83 (1925); cf. *C. A.* **19**, 512.—The claim of Claasz, that *o*-HSC₆H₄NH₂ HCl and aldehydes give benzothiazolines (*C. A.* **6**, 2431), could not be verified. His products on further purification yield thiazoles. Neither ketones nor ketone chlorides condense with HSC₆H₄NH₂. 2-[*m*-Methoxy-*p*-hydroxyphenyl]benzothiazole, pale yellow, m 175.5° (cor.), has a faint, sweet odor; the EtOH KOH soln exhibited a purplish fluorescence. 2-[*m*-*p*-Methylendioxyphenyl]benzothiazole, m 125° (cor.) 2- α -Furylbenzothiazole, m 105° (cor.) (36% yield), has a geranium-like odor. C. J. WEST

Heterocyclic ring systems. II. REINHARD SEKA. *Ber.* **58B**, 1783-7 (1925), cf. *C. A.* **19**, 501.—2,5-Diphenylfuran-3,4-dicarboxylic anhydride with urea at 190-230° gives the corresponding imide, m. 304.45° , sol. in H_2SO_4 with yellow-green color and greenish fluorescence and reprecipitated, unchanged by H_2O . Phenylimide, from the anhydride and CS(NHPh)₂ at 230-40°, yellow, m. 279-80°, sol. in EtOH and AmOH with deep violet fluorescence, in H_2SO_4 with intense yellow color. 2,5-Diphenylpyrrole-3,4-dicarboxylic acid (0.9 g. from 1 g. of the di-Et ester with 3-4 mols. KOH in boiling alc.), m 98° , evolves gas 120-30° and again 175-200° (partial carbonization), sol. in Ac₂O with intense blue-violet fluorescence, in H_2SO_4 -Ac₂O with deep emerald-green color and dark red fluorescence, cautious diln. with H_2O changing the color to corn flower-blue and more H_2O pptg. blue flocks sol. in CHCl_3 with corn flower-blue color. Alkalies change the color to pink. The NH_4 salt gives with AgNO₃ a flocculent Ag salt, with CuSO₄ a light green Cu salt. With Ac₂O at 48-50°, the acid gives the anhydride, m 268° (decompn.), sol. in Me₂CO, AcOH and Ac₂O, with intense blue-violet fluorescence. 3,4-Dimethylthiophene-2,5-dicarboxylic acid, from S(CH₂CO₂Et)₂, Ac₂ and NaOEt in cold

alc., granular powder, m. 327–8° (decompn.); *Ag* salt, amorphous; *Ba* salt, finely granular; *Cu* salt, green. Oxidation of the acid with alk. KMnO_4 under varying conditions always gave, together with much of the unchanged acid, a substance, m. 258° (decompn.), having the compn. of a 4-methylthiophene-2,3,5-tricarboxylic acid C. A. R.

Isomerism of the styryl alkyl ketones. II. The isomerism of the homologs of 2-hydroxystyryl and of 3-methoxy-4-hydroxystyryl methyl ketones. ALEXANDER MCGOOKIN AND DONALD JAMES SINCLAIR. *J. Chem. Soc.* **127**, 2539–44 (1925); cf. C. A. **19**, 481. 2-Hydroxystyryl Et ketone crystals from C_6H_6 in the colorless form, m. 116°; if in the prepn. an excess of 10% NaOH be employed, there results, on pptn. with CO_2 , the yellow isomer, m. 116°, transformed into the colorless form by addn. of a trace of acid to the boiling soln. Decker and Fellenberg's yellow compd. A (C. A. **3**, 1004), m. 246.7°, gives a red alk. salt, the *Ac* deriv., m. 182°, contains C 73.9, H 6.3%, Ac 27.1%; the *carbo*methoxy deriv., sinters 179°, m. 181°, contains C 71, H 6%. The figures do not agree with D. and F.'s formula, $\text{C}_{12}\text{H}_{12}\text{O}_3$. 2-Hydroxystyryl *Pr* ketone, colorless or yellow, m. 113°. The *hexyl* deriv. likewise exists in 2 forms, m. 102.3°, the yellow form being very unstable. 3-Methoxy-4-hydroxystyryl Et ketone, yellow or colorless, m. 93°, the colorless form, from aq. solvents, gives a monohydrate, yellow, m. 79.82°. The *Pr* deriv., yellow or colorless, m. 83°. The following solubilities of 3,4-methylenedioxy-styryl Me ketone in g. per 100 g. EtOH are reported (yellow and colorless isomers): 20°, 1.5, 1.2, 2.2°, 1.8, 1.5; 31°, 4.0, 2.6; 36°, 5.5, 3.3; 43°, 8.0, —; 50°, —, 4.9. 3-Methoxy-4-hydroxystyryl Me ketone (yellow and colorless isomers): 18°, 4.4, 4.8; 9.0, 10.1; 38°, 12.1, 13.7, 39°, 12.1, —; 47°, 16.0, 18.6. All the hydroxystyryl ketones thus far investigated are colored crimson by boiling, concd. HCl, the yellow more rapidly than the colorless isomer C. J. WEST

Mercury and arsenic compounds of some pyrroles. I. HANS FISCHER AND RICHARD MÜLLER. *Z. physiol. Chem.* **148**, 155–79 (1925).—Pyrrole derivs. of the formula $\text{R}_2\text{Hg}(\text{HgCl}_2)$, are readily obtained in cryst. form by treatment of the pyrrole soln. in AcOH with 4% aq. HgCl_2 . Such compds. are decompd. with regeneration of the original pyrrole when the alc. or H_2O suspension is treated with H_2S . This procedure should offer a convenient method for isolating pyrroles from mixts. such as result from reduction of blood pigment. Tetrasubstituted derivs. do not react with Hg. It is improbable, therefore, that Hg is linked to N, a linkage to C being more likely, and this view is supported by the fact that Hg derivs. of PhOH and *p*- $\text{MeC}_6\text{H}_4\text{OH}$ are decompd. in the same manner by H_2S . HgCl_2 deriv. of 2,3,5-trimethylpyrrole, m. 120.5° (decompn.), is difficultly sol. in H_2O and insol. in most org. solvents, but sol. in AcOH. When dissolved in MeAc or pyridine a transformation occurs, since the soly. in AcOH and the m. p. are changed. H_2S decomp. it into the original trimethylpyrrole. HgCl_2 deriv. of 2,4-dimethylpyrrole, m. 136° (decompn.), was prepd. in 93% yield by the same method. Treatment with H_2S liberates the original pyrrole. HgCl_2 deriv. of pyrrole, m. 113° (decompn.). By changing the conditions of temp. and solvent, other products, m. resp. 125°, 165–70° and 150–5°, were obtained. Pyrrole is regenerated by H_2S . HgCl_2 deriv. of *N*-methylpyrrole, decomp. 120–30°. HgCl_2 deriv. of 2,5-dimethyl-3-carbethoxypyrrole (I), m. 239° (decompn.), may be obtained either from AcOH soln. or by fusion of the components. Dilm. of the pyridine soln. with H_2O , gives 2 cryst. products, m. 255° and 170° (decompn.). HgCl_2 deriv. of 2,4-dimethyl-3-carbethoxypyrrole (II), m. 218° (decompn.), was obtained by addn. of alc. solns. of the pyrrole and HgCl_2 and dilm. with H_2O . Cryptopyrrole also forms an insol. HgCl_2 deriv. from which the original substance was recovered by treatment with H_2S . 2,4-Dimethyl-3-acetyl-5-carbethoxypyrrole reacts with HgCl_2 but the product could not be purified sufficiently for analysis. It is believed that mercuration occurs in the side chain. The original substance was recovered as usual by decompn. with H_2S . Treatment of I and II with 1 in KI soln. removes the Hg and substitutes I in the 4- and 5-positions, resp. Hemin was reduced in the usual manner by means of HI in AcOH and the acidic and basic fractions were sepd. by steam distn. From each fraction the HgCl_2 deriv. was pptd. and decompd. by H_2S . In this way hemopyrrole and hemo- and cryptopyrrolecarboxylic acids were prepd. in cryst. form. Tetrasubstituted pyrroles remained in the filtrates from the HgCl_2 pptn. Oxidation of Ph_4C_2 with O_3 gave Ph_2CO and oxidation of dibiphenyleneethene gave a substance, m. 250–2° and diphenyleneketone. Arsenic derivs. of several pyrroles were prepd. in cryst. form but none of these showed trypanocidal action. 2,5-Dimethyl-3-carbethoxypyrrol-5-arsonic acid, m. 245–7° (decompn.), was prepd. by heating the pyrrole with As_2O_5 at 120°. 2,3,5-Trimethylpyrrol-4-arsonic acid (III), m. 230–5° (decompn.), from the pyrrole and As_2O_5 at 95°. Pyrrol-arsonic acid (IV), m. 120–30° (decompn.), could not be crystd. It gave a strong aldehyde reaction with Ehrlich's reagent. H_2S ppts. As_2S_3 from its soln. in mineral acid. Re-

duction of **III** by $\text{Na}_2\text{S}_2\text{O}_4$ and of **IV** by SnCl_2 and **III** gave unstable products without pharmacological action.

A. W. DOX

Replacement of halogens from aromatic compounds. R. H. CLARK AND R. N. CROZIER. *Trans. Roy. Soc. Can. Sec. III* [3], **19**, 153-4 (1925).—C. and C. attempted to find out whether electronic tautomerism explained the substitution reactions of the C_6H_6 ring. Thirteen compds. were heated separately with halogens and alc. KOH, NaOMe or NaOEt. A table containing the results together with those calcd. from the electronic tautomerism hypothesis is given. The replacement found in *o*- and *m*- $\text{C}_6\text{H}_4\text{Cl}_2$, 1,2,4- $\text{C}_6\text{H}_3\text{Cl}_3$, 1,2,4,5- $\text{C}_6\text{H}_2\text{Cl}_4$ and C_6Cl_6 point to the electronic picture of the C_6H_6 nucleus while 2,4- $\text{Cl}_2\text{C}_6\text{H}_3\text{NH}_2$, 2,4,6- $\text{Cl}_3\text{C}_6\text{H}_2\text{OH}$, 2,6,4- $\text{Cl}_2(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{NH}_2$, *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$ and $\text{C}_6\text{Br}_6\text{OH}$ behave in accordance with the isometric equl. postulated by electronic tautomerism.

J. W. SHIPLEY

Sulfuryl chloride. **IV.** Further studies on a new chlorinating agent. Preparation of polychloro derivatives of toluene. OSWALD SILBERRAD. *J. Chem. Soc.* **127**, 2677-84 (1925); cf. C. A. **19**, 3197.—Using a mixt. of PhMe (181 g.), AlCl_3 (10 g.) at 70° and varying amts. of chlorinating agent (SO_2Cl_2 contg. 1% S_2Cl_2), the following products were obtained: With 280 g. agent 88% of a mixt. of 2- and 4-Cl derivs (oxidation of 50 g. gave 21 g. *p*- and 16 g. *o*- $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$), with 560 g. agent, finally heating a few min. at 100° , 220 g. practically pure 2,4- Cl_2 deriv.; with 840 g. agent, run in during 15 hrs., 83% of a mixt. of about equal parts of 2,4,5- and 2,3,4- Cl_3 deriv., sepn. by crystn. from EtOH gave 40 and 34%, resp. Further action of the chlorinating agent on the 2,4,5- Cl_3 deriv. gives principally the 2,3,4,5- Cl_4 compd.; that some 2,3,4,6-isomer results is shown by nitrating the product from the mother liquor; the method is not recommended for the prepn. of any tetra-Cl deriv., for not only are the isomers formed in such proportions that there is considerable difficulty in sepg. them but also the tri-Cl derivs. show a great tendency to pass directly into the penta-Cl deriv. under the influence of this reagent. With 1632 g. chlorinating agent, there results practically quant. the penta-Cl deriv., m. 217.5° ; this is sol. in 3-4 vols. PhMe at 87° and in 22 vols. at 17° . The penta-Cl deriv. (100 g.) treated with 10 g. AlCl_3 and 200 g. chlorinating agent, gave 88 g. of unchanged product and a compd., m. $272-4^\circ$, possibly $\text{C}_6\text{Cl}_5\text{CH}_2\text{C}_6\text{Cl}_4\text{Me}$.

C. J. WEST

Further study of the utility of ethyl γ,γ -diethoxyacetoacetate as a reagent for the synthesis of glyoxaline. E. W. RUGELEY AND T. B. JOHNSON. *J. Am. Chem. Soc.* **47**, 2995-3002 (1925).—Since the practicability of Pyman's syntheses of histidine depends upon the synthesis of certain glyoxaline derivs., the study of $(\text{EtO})_2\text{CHCOCH}_2\text{CO}_2\text{Et}$ (**I**) has been continued (cf. J. and Pucher, C. A. **16**, 1573). $(\text{EtO})_2\text{CHCO}_2\text{Et}$ is more conveniently prepd. on a large scale by agitating the moist Ag salt in moist Et_2O with EtI at room temp. for 10-12 hrs. The best sample of $(\text{EtO})_2\text{CHCOC}(\text{NOH})\text{CO}_2\text{Et}$ which could be obtained contained 63-5% of the pure NO compd. All attempts to prep. the corresponding NH_2 deriv. by reduction of the NO deriv. failed. While **I** appears to react normally with Br in CS_2 to give the α -Br deriv., the light red oil obtained could not be purified by distn. It shows no tendency to react with $\text{CO}(\text{NH}_2)_2$ to form a glyoxaline deriv.; further, it does not react smoothly with NH_3 . When satd. with HBr there results *Et* α -bromoglyoxalacetate, m. 119° . **I** and ClCH_2OMe are condensed by Na to give 44% of *Et* α -methoxymethyl- γ,γ -diethoxyacetoacetate, b_4 130° , n_{23} 1.4387. *Di-Et* γ,γ -diethoxyacetosuccinate, b_3 153° , n_{21} 1.4370, results in 48% yield from $(\text{EtO})_2\text{CHCO}_2\text{Et}$ and $(\text{CH}_3\text{CO}_2\text{Et})_2$ with Na or in 43-5% yields by the alkylation of **I**. Hydrolysis of this ester gives glyoxalpropionic acid, which reacts normally with NH_3 and HCHO to give glyoxalinepropionic acid. The yield, however, is so low that the ketone ester, from which it is prepd., cannot displace levulinic acid as the best practical source of this compd.

C. J. WEST

Nitro compounds with special reference to the nitration of *m*-chloronitrobenzene and *p*-chlorotoluene. H. H. HODGSON. *J. Soc. Dyers Colourists* **41**, 327-9 (1925).—The work of Holleman (cf. C. A. **3**, 1010; **4**, 754) is reviewed. Fifty g. of *p*-toluidine is diazotized as usual and the clear soln. is added dropwise down the reflux to a soln. contg. 5 g. Cu_2Cl_2 , 16 cc. concd. HCl and 20 cc. H_2O , on the water bath. After 2 to 3 hrs. of heating for complete decompn., the mixt. is steam-distd.; the volatile but slightly impure 4- $\text{ClC}_6\text{H}_4\text{Me}$ passes over. The latter is made just alk. with NaOH to keep back any *p*-cresol formed as a by-product and again steam-distd. Final yield of 4- $\text{ClC}_6\text{H}_4\text{Me}$, 52.5 g. Com. pure samples of 2-nitro- and 3-nitro-4-toluidines were recrystd. 4 times from water and 6 times from alc. and the 3-nitro-4-toluidine 6 times again from alc. These were then converted resp. to 2-nitro- and 3-nitro-4-chlorotoluene as above. Freedom from admixed nitroresols was secured by steam distn. from NaOH soln. Yields about 90%. Several recrystns. of 4,2- $\text{Cl}(\text{O}_2\text{N})\text{C}_6\text{H}_2\text{Me}$ gave a product,

m. 37°, and the 4,3-Cl(O₂N)C₆H₃Me after several distns. had a max. setting point of 4°. It is std. that the product m. 37° consisted of 93.9% 4,2- and 6.1% 4,3-Cl(O₂N)-C₆H₃Me, and that the product setting at 4° consisted of 6-7% of the 4,2- and 93-4% of the 4,3-compd.

Tetrahydroindazoles. K. v. AUWERS, L. FR. v. SASS AND W. WITTEKINDT. *Ann.* **444**, 195-220 (1925); cf. *C. A.* **18**, 834.—1-Methyl-3-hydroxymethylencyclohexan-4-one (I) benzoate (II), m. 96-7°. 1,3-Dimethyl-4-hydroxymethylencyclohexan-5-one (III), b₁₀ 92°, d₄^{16.5} 1.0221, d₄²⁰ 1.019, n 1.49232, 1.49733, 1.50993, 1.52694 at 16.5° for α, He, β and γ, n_D²⁰ 1.4958. Benzoate (IV), m. 87-8°. I and H₂NCONHNH₂. AcOH at 0° give the labile (V) and stable (VI) forms of 5-methyltetrahydroindazole-N-carboxamide, m. 170° and 158°, the ratio being 3:1; V is changed into VI by warming with EtOH-H₂SO₄ or AcOH. With H₂NCONHNH₂.HCl only the labile form results. The benzoate, m. 188-93°, results from II; warmed with AcOH, there results VI; with EtOH-H₂SO₄, V. With 2 mols. H₂NCONHNH₂. AcOH there results VI and the disemicarbazone, m. 206°, then 230-5° (decompr.). III and H₂NCONHNH₂. AcOH give the labile carboxamide, m. 133-4°, then 148-9°, with the HCl salt, there results 60% of the labile form and 20% of the stable form, m. 151-2°; the benzoate, m. 190°; the disemicarbazone (VII), m. 188-91°, then 228-32°. The anilide of III, b₂₃ 218-20°, yellow oil, also yields VII. 5-Methyl-4,5,6,7-tetrahydroindazole (VIII), m. 74-5.5° (picrate, yellow, m. 156-7°). The 4,6-di-Me deriv. (IX), m. 76-7° (picrate, dark yellow, m. 167-8°). With PhNHNH₂, I or II gives the 2-Ph deriv. of VIII, m. 68-9° (perchlorate, m. 158-60°) if the free base or the AcOH salt is used, or the 1-Ph deriv., m. 62.5-3.5° (perchlorate, m. 109-11°), if the HCl salt is used. II and PhNHNH₂. AcOH give a mixt. of the isomers which could not be sep'd. The anilide of I, m. 150.5-1.5°. IV and PhNHNH₂. AcOH give the compd. C₂₀H₂₄O₂N₂, m. 103-6°, which is sapond. to the 2-Ph deriv. of IX, light yellow oil, b₁₃ 194°, d₄^{16.6} 1.0625, n 1.57793, 1.58445, 1.60117 at 16.6° for α, He and β. Perchlorate, m. 199-200°. III and free PhNHNH₂ give a diphenylhydrazone, m. 171-2° which gives a mixt. of isomers on sapon., sep'd. by means of the perchlorates. The 1-Ph deriv., b₁₃ 187°, m. 71-2°, d₄²⁰ 1.0660, d₄^{99.7} 1.0096, n 1.56990, 1.57555, 1.58967 at 20.5° (supercooled) for α, He and β; 1.53791, 1.54329 at 99.7° for α and He. The ratio of the 1- and 2-Ph derivs. was 1:3. The 1-Ph perchlorate, m. 177-8°. III and PhNHNH₂.HCl at 0° give the isomers in the ratio of 1:1, but the total yield is only 30%. At 40°, the yield is 50%, the ratio of 1 to 2, 7:1; at 100° the yield is again 50%, the ratio 9:1. 2-Benzyl-5-methyl-4,5,6,7-tetrahydroindazole, yellow oil, b₂₁ 203° (50% yield); picrate, yellow, m. 132-3°. This also results in 90% yield from VIII and PhCH₂Cl and EtONa. 2-Benzyl-4,6-dimethyl-4,5,6,7-tetrahydroindazole, b₁₂ 201.5-2°, m. 36-7.5°, d₄^{16.1} 1.0423, n 1.55100, 1.55556, 1.56676, 1.57659 at 16.1° for α, He, β and γ; picrate, light yellow, m. 172°. From IX and PhCH₂Cl there results a mixt. of this deriv. with the 1-benzyl deriv., yellow oil, b₁₃ 191-2°, d₄^{17.4} 1.0407, n 1.53963, 1.54391, 1.55446 and 1.56371 at 17.4° for α, He, β and γ. This does not form a picrate. The 2-Et deriv. of VIII, b₁₆ 121°; the 1-Et deriv., b₂₂ 124°; the 2 picrates, yellow, m. 152-3° and 113-4°. The 2-Et deriv. of IX, b₁₃ 118-8.5°, d₄^{15.6} 0.9716, n 1.49584, 1.49915, 1.50417, 1.51393 at 15.5° for α, He, β and γ; picrate, yellow, m. 139-41°. The 1-Et deriv., b₁₆ 121-3°, d₄^{15.4} 0.9753, n 1.49892, 1.50232, 1.51054, 1.51787 at 15.4° for α, He, β and γ; picrate, yellow, m. 114-5°. 2-Carbelthoxy deriv., b₂₀ 182-2.5°, m. 63°, sapond. by alkali to IX; heated to 230-5°, there results the 2-Et deriv. 2,5-Dimethyl-4,5,6,7-tetrahydroindazole, b₁₄ 114°; picrate, yellow, m. 170-1°. 1,4,6-Trimethyl-4,5,6,7-tetrahydroindazole, b₁₃ 118-9°, d₄^{19.8} 0.9886, n 1.49758, 1.50115, 1.50958, 1.51691 at 19.8° for α, He, β and γ; picrate, m. 146-7°. III gives a M₂ ether, b₁₃ 117°; the methylsemicarbazide is a clear yellow oil, which is sapond. to the 2,4,6-tri-Me deriv., b₁₂ 124°, d₄^{25.4} 0.9823, n 1.49398, 1.49728, 1.50528 at 25.4° for α, He and β; picrate, m. 174-5°. 4,6-Dimethyl-2-carbomethoxy-4,5,6,7-tetrahydroindazole, b₁₅ 167-8°, m. 74-5°. C. J. WEST

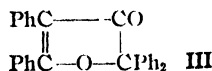

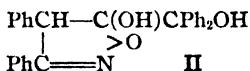

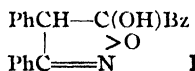

The two forms of o-nitrotoluene. ROBERT H. CLARK AND ROBERT N. CROZIER. *Trans. Roy Soc. Can. Sec. III* [3], 19, 157-8 (1925).—The β-form was prep'd. by keeping the α-modification at the temp. of solid CO₂ and Et₂O for some considerable time. The d., mol. wt. and n_D²⁰ were practically identical for the 2 forms, showing that polymerization was not responsible for them. Chem. tests made in an effort to replace the negative NO₂ group by a negative NH₂ or HO group showed in the majority of cases that displacement was greater with the β- than with the α-form. C. and C. conclude that the evidence supports the electronic hypothesis as an explanation for the existence of the

2 forms and suggest $\text{MeC}_6\text{H}_4\text{NO}_2 \rightleftharpoons \text{MeC}_6\text{H}_4\text{N}^+\text{O}_2^-$ as a plausible structure. J. W. S.

Firmness of the attachment of organic residues. III. JULIUS V. BRAUN, RUDOLF

PUSSGANGER AND MARTIN KÜHN. *Ann* **445**, 201-24(1925); cf. *C. A.* **18**, 1830.—*β*-Bromoallylmethylaniline, b_{13} 136-8° (HCl salt, picrate and methiodide, oily), heated with 2 mols. KOH for 16 hrs. gives 50% propargylmethylaniline (I), b_{13} 108-11° (HCl salt, m. 142°; methiodide, m. 130-2°; picrate, oily). With BrCN there results methylphenylcyanamide, b_{12} 137°, m. 28°, and $\text{CH}_2\text{CCH}_2\text{Br}$, which combines with the original base to give the quaternary bromide, $\text{PhNMe}(\text{CH}_2\text{C}:\text{CH})_2\text{Br}$, m. -170°; the reaction is incomplete and about 50% of the original base is recovered. PhCH_2NMe and $\text{CH}_2\text{CBrCH}_2\text{Br}$ give the amine, $\text{PhCH}_2\text{NMeCH}_2\text{CBrCH}_2$ (impure sample, b_{13} 126-30°) (HCl salt, m. 140°; picrate, orange, m. 121°; methiodide, yellow, m. 111°); boiling KOH in dil. EtOH gives propargylmethylbenzylamine, b_{11} 101-3° (Ag complex, orange, explodes on rapid heating; HCl salt, m. 155°, picrate, oily). The reaction with BrCN is more energetic than with I and is completed in a few min. The products are PhCH_2Br and propargylmethylcyanamide, b_{12} 90°. The propargyl residue appears to be more strongly bound to O than is the allyl residue. Benzoyltrimethylenylaniline, b_{11} 186-7°, m. 74-5°, in 90% yield by reduction of the nitrile with Na and EtOH, with PBr₅ this gives 30% of trimethylenyl bromide (II), b_{15} 106°. PhCH_2NMe and I give trimethylenylbenzylmethylamine, b_{11} 105-6° (picrate, m. 88°). The energetic action of BrCN gives trimethylenylmethylcyanamide, b_{11} 80-3°, and PhCH_2Br . Trimethylenylaniline, b_{12} 113-4° (HCl salt, picrate, methiodide are oily), BrCN gives $\text{PhN}(\text{CH}_3)\text{CN}$, b_{12} 135°, m. 28°. II and PhOH with K_2CO_3 in Me_2CO give 65% of trimethylenyl Ph ether, b_{12} 95°, b. 214°, which is unchanged after heating at 250°. Trimethylenylrhodanide, b_{12} 65-7°. Benzoyltetramethylenylaniline, b_{12} 191-3°, m. 102° (80% yield); PBr₅ gives 31% tetramethylenyl bromide (III), b_{15} 81-3°, d_4^{25} 1.360, this is more stable than II; when 0.2 g. of each is warmed at 100° with 200 parts H_2O , II is completely hydrolyzed in 10 min., while III is largely unchanged, after 1 hr. only 39% of the Br of III is split off; with Me_3N the reaction is slow and in 30% EtOH after 24 hrs., 85% of the III is unchanged; the quaternary base, $\text{C}_8\text{H}_{14}\text{NBr}$, is hygroscopic and m. 214°. Tetramethylenylmethylamine, b_{12} 135° (HCl salt, oily, chloroplatinate, ochre-yellow, decomps. 178°); BrCN gives tetramethylenylphenylcyanamide, b_{11} 158°, indicating that the tetramethylenyl residue is more firmly bound to the N than is the Me group. Tetramethylenylbutylaniline, pale yellow liquid, b_{11} 161-2° (picrate, orange, m. 128°); it reacts very slowly with BrCN and after 0.5 hr.'s heating, 0.5 can be recovered, the reaction products are III and phenylbutylcyanamide, b_{11} 156-8°. α -Thenyl bromide, b_{15} 80-2°, in 90% yield from the alc. and PBr₅, on standing it gradually splits off HBr and gives a dark resin; it is also hydrolyzed by H_2O , splitting off HBr; it easily combines with tert. bases. α -Thenyltrimethylammonium bromide (IV), very hygroscopic, m. 172°. α -Thenylmethylbenzylamine, b_{12} 148-52° (picrate, m. 95°; methiodide, m. 165°). With BrCN there results a Br- and S-free oil, b_{13} 60-85°, and a 2nd fraction, b_{13} 142-50°, the lower fraction gives with Me_3N IV, which was further characterized by transforming it into the chloride and forming the chloroplatinate V, yellow, decomps. 179°. Thenylallylaniline, b_{14} 161-5° (picrate, m. 124-5°); the reaction with BrCN does not yield well-characterized products, but it appears that $\text{CH}_2\text{CHCH}_2\text{Br}$ is split off. Thenylmustard oil, b_{20} 141-2°. Thenylphenylthiourea, m. 123°. Furomethylbenzylmethylamine, b_{13} 131-3° (methiodide, m. 135°); decomps. with BrCN gives an oily quaternary bromide, which forms a dark yellow, amorphous Pt salt, m. 140°, and a yellow oil, yielding with Me_3N the known $\text{C}_6\text{H}_5\text{OCH}_2\text{NMe}_3\text{Br}$, whose Pt salt, m. 148°. Thenylfuromethylmethylamine, b_{14} 132-5° (picrate, m. 78°; methiodide, m. 110°). Reaction with BrCN gives an oily quaternary bromide and thenyl bromide, characterized as V. C. J. W.

Isoxazoline oxides. IV. Benzoyldiphenylisoxazoline oxide. 2nd paper. E. P. KOHLER. *J. Am. Chem. Soc.* **47**, 3030-36(1925); cf. *C. A.* **18**, 2518, 3190.—The product m. 123°, obtained by the action of AcOK upon $\text{PhC}(\text{CHPhNO}_2)\text{HCHBrBr}_3$ is not an isoxazoline oxide but a hydroxyisoxazoline (I). When any 1 of the 4 isomers of this Br compd. is boiled with $\text{C}_6\text{H}_5\text{N}$ in MeOH there results a quant. yield of 2 isomers, m. 151° and 183°, which readily change into the 3rd. α, γ, δ -Triphenylbutanetrione oxime,

for which the method of prepn. is given, is stable only in solid form; in CHCl_3 minute traces of acid rapidly transform it into the purple anhydride, while in EtOH it gives I. With excess PhMgBr (because I always contains MeOH of crystn.) I gives 90% of 3,4-diphenyl-5-hydroxy-5-diphenylcarbinylisoxazoline (II), m. 170-1°; it loses H_2O with difficulty and can be recrystd. from AcOH, AcCl or Ac_2O ; EtOH-NaOH splits off H_2O .

forming 3,4-diphenyl-5-diphenylcarbonyloxazole, m. 157-8°; this is the sole product when I reacts with an equiv. amt. of PhMgBr II and AcCl in MeOH give the Me ether, m. 182-3°. A by-product of the above reaction is 2,2,4,5-tetraphenyl-3-furone (III), pale yellow, m. 178°. Oxidation with O₃ gives a compd., C₂₁H₁₆O₆, yellow, m. 150°, which is further oxidized by CrO₃ to equiv. amts. of BzOH and Ph₂C(OH)CO₂H.

C. J. WEST

"Hesperidin" from certain plants. O. A. OESTERLE AND G. WANDER. *Helvetica Chim. Acta* **8**, 519-36 (1925).—*Scrophularia nodosa*, *Hyssopus officinalis*, fol. bucco, fruct. conii, herb. conii, pennyroyal, *Mentha crispum*, *Mentha pulegium*, *Toddalia aculeata*, and *Linaria genistifolia*, supposed chiefly on microchem. evidence to contain hesperidin (I), really yield the rhamnoglucoside *diosmin* (II), C₃₄H₄₄O₂₁·2H₂O, differing from I in its insol. in aq. NH₃. The plant material was extd. 3 times for 2-3 days with 2% aq. NaOH and the ext. was pptd. with HCl, the washed ppt. dissolved in dil. NaOH, and pptd. with CO₂, this was repeated 10-20 times until no further lightening of the color occurred. Further purification is by boiling with alc., extn. with dil. NH₄OH, and repeated soln. in dil. NaOH and reprecip. with CO₂ until well-marked spherocrystals are formed. Heated a short time with 33% KOH, or better at 130-40° for 4 hrs. with 20 parts aq. alc. (1:1) 5% H₂SO₄, II yields glucose, rhamnose, and *diosmetin* (III), (luteolin Me ether), 3,4-HO(MeO)C₆H₃C·CH·CO·C₆H₂(OH)₂O, occurring in parsley with apiin

(Vongerichten, *Ber.* **33**, 2334 (1900)) and obtained from hesperetin by ring closure (O and Kueny, *C. A.* **10**, 2472). After filtering off unchanged II from the hot soln. III seps. on addn. of much H₂O and is best purified over the acetate, m. 195-6°. With hot concd. KOH it gives 3,4-HO(MeO)C₆H₃CO·Me, 3,4-HO(MeO)C₆H₃CO₂H- and 2,4,6-C₆H₂(OH)₃, heated with HI it gives luteolin. The name "hyssopin" is to be discarded (cf. Tunnann, *C. A.* **12**, 2314).

M. HEIDELBERGER

Syntheses in the fatty-aromatic series. XVI. Chlorinated amines and amino acids. JULIUS V. BRAUN AND HANS REICH. *Ann.* **445**, 225-46 (1925); cf. *C. A.* **18**, 829. —PhOCH₂Ph and 38% HCl give a mixt. of *o* and *p*-HOCH₂C₆H₄CH₂Ph, the total yield after 36 hrs. being 75%. Similarly behaves a mixt. of PhCH₂Cl and PhOH. *p*-Cresyl benzyl ether, b₁₂ 165°, α -naphthyl benzyl ether, b₁₂ 200°, m. 61°, β -C₁₃H₇OCH₂Ph, PhOCH₂C₆H₄CH₂OPh also show the same qual. behavior in that they yield no Cl-contg. decompn. products but small amts. of PhOH or MeC₆H₄OH and products of high mol. wt., partly sol. in alkali. *p*-PhOCH₂C₆H₄CN and PhONa give 80% of *p*-phenoxyethylbenzonitrile, b₁₂ 205°, m. 65°, reduction gives a mixt. of primary and sec. base, the latter predominating; *p*-phenoxyethylbenzylamine, m. 78°, absorbs CO₂ readily from the air and was analyzed as the Bz deriv., m. 116°, HCl salt, m. 260°; picrate, yellow, m. 197°. *p*-Phenoxyethylbenzyl alc., b₁₂ 215-20°, m. 106°; the bromide, b₃ 210°. *p*-Ethoxyethylbenzonitrile, b₁₃ 135°, reduction gives 50% of *p*-ethoxyethylbenzylamine, b₁₃ 135° (HCl salt, m. 235°; picrate, m. 150°) and 30-5% of *di-p*-ethoxyethylbenzylamine, b₁₂ 255°. *p*-Ethoxyethylbenzyl alc., b₁₃ 152°, bromide, b₁₃ 148° (not pure); cyanide, b₁₂ 165°, which is reduced to 25% of *p*-ethoxyethylphenylethylamine, b₁₃ 147° (HCl salt, m. 180°; picrate, m. 130°), and 40-5% of *di-p*-ethoxyethylphenylethylamine, b₁₃ 270-5° (HCl salt, m. 250°, Nc compd., m. 58°). *p*-Chloromethylbenzylamine-HCl, does not m. 300°; chloroplatinate, ochre-yellow, m. 226°; picrate, m. 185°. *p*-Chloromethylphenylethylamine-HCl, does not m. 300°; chloroplatinate, does not m. 300°; picrate, m. 145°. *m*-Bromomethylbenzonitrile, m. 93° (80% yield); *m*-phenoxyethylbenzonitrile, b₁₂ 183-5°, m. 51°. Reduction gives a mixt. of *m*-phenoxyethylbenzylamine, b₁₆ 220° (HCl salt, m. 170°; picrate, m. 179°), and *di-m*-phenoxyethylbenzylamine, b. 290°. *m*-Ethoxyethylbenzonitrile, b₁₂ 133°, is reduced to a mixt. of *di-m*-ethoxyethylbenzylamine, b₁₄ 250° (picrate, m. 212°), and *m*-ethoxyethylbenzylamine, b₁₅ 150-2° (HCl salt, m. 156°; picrate, m. 131°); the corresponding alc., b₁₁ 140-2°; bromide, b₁₂ 140-5°; cyanide, b₁₁ 155°, which is reduced to *m*-ethoxyethylphenylethylamine, b₁₁ 145° (HCl salt, m. 107°; picrate, m. 182°), and *di-m*-ethoxyethylphenylethylamine, b₁₁ 240-5° (HCl salt, m. 135°). *m*-Chloromethylbenzylamine (I) HCl, m. 169°; chloroplatinate, m. 219°; picrate, m. 173°. *m*-Chloromethylphenylethylamine-HCl, decomp. 177-80°; picrate, m. 172°. I gives a Bz deriv., m. 92°, which yields a nitrile, m. 89°, sapon. gives *m*- β -aminoethylphenylacetic acid, m. 210°. *o*-Ethoxyethylphenylethylamine, b₁₁ 140° (75% yield); HCl salt, m. 117°; picrate, reddish yellow, m. 163°. The sec. amine, b₁₁ 250°. *o*-PhOCH₂C₆H₄CH₂NH₂, with HBr or HCl, gives the same phenol base, C₁₄H₁₃ON, b₁₄ 225-35° (slight decompn.), m. 158-9°; exhaustive methylation gives the compd., C₁₈H₂₃ONi, m. 181-3°. *o*-Chloromethylbenzylamine-HCl, m. 222°; chloroplatinate, m. 218°; picrate, m. 187°. *o*-Chloromethylphenylethylamine-HCl, m. 209°; *p*-nitrobenzoyl compd., m. 120-1°. *Di-m*-chloromethylphenylethylamine-HCl, m. 220°; Bz deriv., m.

95°; the corresponding *o*-deriv.-HCl, m. 154°. *o*-Chloromethylbenzylamine gives a Bz deriv., m. 119°, which in turns gives a *nitrile*, m. 135°, saponid. to *o*-aminomethylphenylacetic acid, decomp. 202° (HCl salt, m. 154°); the *Et* ester-HCl, m. 167°; the acid, heated at 160-70°, gives a *lactam*, m. 150°. *o*-Chloromethylphenylethylamine yields an oily Bz deriv., whose *nitrile*, b₁₂ 290-300° and gives *o*-aminoethylphenylacetic acid decomps. 228° (HCl salt, m. 218°); its *lactam*, m. 159°. Cl(CH₂)₃C₆H₄CN gives a *phthalyl* deriv., m. 138°, saponid. to *o*- γ -aminopropylbenzoic acid, m. 213-4° (HCl salt, m. 213.4°), whose *lactam*, m. 100°. C. J. WEST

Two mixed anhydromonohydroxybenzoic acids and their conversion into xanthonecarboxylic acids. RICHARD ANSCHÜTZ, WALTER STOLTENHOFF AND FRITZ VOELTER. *Ber.* 58B, 1736-41(1925); cf. C. A. 16, 3084.—*o*-(*p*-MeC₆H₄O)C₆H₄CO₂H, m. 126° (Ullmann and Zlokasoff, *Ber.* 38, 2111(1905), give 118°); *Ag* salt, cryst. powder sensitive to light. With KMnO₄ the acid gives 98% of anhydro-*o*,*p'*-hydroxybenzoic acid (*diphenyl ether-o,p'*-dicarboxylic acid), m. 220°. Salts: *di-Ag*, sensitive to light; *Ca*, coarsely granular ppt. with 1 H₂O, weathers in the air; *Cu*, green. *Di-Me* ester, m. 72.5°. *Di-Et* ester, faintly yellow, b₁₉ 229°. *Dichloride*, m. 165°. *Diamide*, m. 238°. *Dianilide*, m. 215°. The acid with concd. H₂SO₄, AcCl or SOCl₂ or the dichloride with anhyd. (CO₂H)₂ yields *xanthone-2-carboxylic acid*, m. above 300°; *Ag*, *Ca*, *Cu* (green, with 1 H₂O) salts; *Me* ester, m. 185°; *Et* ester, m. 152°; *chloride*, m. 173°, faintly yellowish; *amide*, m. about 324° (decompn.); *anilide*, m. 271°. Anhydro-*o,m'*-hydroxybenzoic acid (*diphenyl ether-o,m'*-dicarboxylic acid), from *o-m*-(MeC₆H₄O)C₆H₄CO₂H, m. 215°; *di-Ag* and *Cu* (pale green) salts; *di-Me* ester, m. 92°; *di-Et* ester, m. 44°, b₁₆ 181°; *dichloride*, could not be isolated in pure form; *diamide*, m. 284°; *dianilide*, m. 232°. The dichloride slowly heated to 145° in (CHCl₃)₂ with somewhat more than the calcd. amt. of anhyd. (CO₂H)₂ gives 25% of *xanthone-1- or 3-carboxylic acid*, m. 312°; *Ag* salt; *Cu* salt, green ppt. with 1 H₂O; *Me* ester, m. 212°. C. A. R.

Dissociation into free radicals of substituted dixanthyls. II. The dissociating influence of the cyclohexyl group. J. B. CONANT AND L. F. SMALL. *J. Am. Chem. Soc.* 47, 3068-77(1925); cf. C. A. 19, 988.—*p*-Chlorobenzylidenexanthane, yellow, m. 131-1.5°, in 60% yield from *p*-ClC₆H₄CH₂MgCl and xanthone; the xanthydrol could not be purified because of the ease with which it lost H₂O; *perchlorate*, yellow, darkens 200°, fuser 209°. Reduction of the H₂SO₄ or HCl soln. with V salts gave *di-[p-chlorobenzylidixanthyl]ethane*, m. 147-9° (in air, turning brown), 152° (in CO₂, with no color change); in PhBr this absorbed 100% of the amt. of O calcd. to form the peroxide in 4 min. at 20.8°; a sample which had stood in the air for 48 hrs. absorbed the same amt. in 5 min.; after heating 1 hr. at 80°, it absorbed 77% of the theoretical amt. of O, while after 1 hr. at 100°, there was no O absorption. *Isoamylxanthydrol*, m. 95-7° (total yield, 80%), slowly decompd. in contact with the air. The perchlorate, yellow, m. 165°; reduction gives *disoamylidixanthylethane*, m. 137-45° (in air); 158-60° (CO₂); mol. wt., av. 505 (in freezing C₆H₆ under N); in PhBr after 30 hrs. at 21°, 180% of the O required for peroxide formation was absorbed, the end product being xanthone. The solns. when heated undergo reversible color changes which point to an appreciable dissociation at higher temps. *Hexylxanthyl perchlorate*, yellow, m. 126-7°; 1 g. dissolves in about 200 g. glacial AcOH at 25°; it slowly decomps. on standing. *Di-hexylidixanthylethane*, m. 138° (CO₂), sol. in 18 parts boiling Me₂CO, 80 parts Me₂CO at 0°; mol. wt. in *p*-MeC₆H₄Cl, 524, 554; the O absorption increased from 21.2 to 209% in from 1.5 to 55 hrs. The color changes on heating are similar to those of the Am deriv. *Cyclohexylxanthydrol*, m. 158-9°; *perchlorate*, yellow, m. 163° (decompn.); *dicyclohexylidixanthyl*, m. 110-3° (?); the properties of the solns. show that this substance is considerably dissociated in soln. at room temp. The red solns. on diln. show wide deviations from Beer's law and rapidly absorb O, becoming light yellow and yielding a cryst. *peroxide*, m. 147-8°, which dissolves in concd. H₂SO₄ with an orange-yellow color. C. J. W.

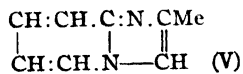

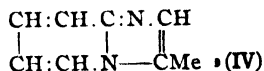

Some new derivatives of phenylarsonic acid. K. KEIMATSU AND S. KAKINUMA. *J. Pharm. Soc. Japan*, No. 520, 520-9(1925).—With a view to prepg. a compd. which contains twice as much As as arsenamine methods of synthesizing phenylenediarsonic acid were first studied, by Bart's diazo method (C. A. 17, 82). (1) Starting with *p*-HOC₆H₄AsO₃H₂ (I): I was nitrated according to Benda and Berthelm (C. A. 6, 749), giving 3,4-O₂N(HO)C₆H₃AsO₃H₂, which was reduced to the NH₂ acid with Na₂S₂O₄. Then the product was diazotized, and H₃AsO₄ added. The free phenylenediarsonic acid thus formed is very difficult to sep. The di-Na salt is also too sol. to be obtained in cryst. form. When equal vols. of free phenylenediarsonic acid and the di-Na salt are mixed, there are obtained small white crystals of the mono-Na salt of 4-hydroxy-1,3-phenylenediarsonic acid, which become brownish gray at 220°, but do not m. even at 290°. Further nitration of this could not be accomplished by Benda's method.

However, by heating at 50–60°, neutralizing, adding the calcd. amt. of acid, drying and then extg. with MeOH, light yellowish crystals of a mono-nitro deriv. of 4-hydroxy-1,3-phenylenediarsonic acid are obtained. Whether this NO₂ is in the 5-position or not is not yet ascertained. (2) Starting with *o*-HO-C₆H₄AsO₂H₂ (II): By Benda's method, II was nitrated. The product decomps. 229–30°. When this is recrystd. from H₂O, it m. 246–7° (III); another nitro compd. (IV) is obtained from the mother liquid. III is identical with B.'s 2,5-HO(O₂N)₂C₆H₃AsO₂H₂. IV decomps. 277–8° and is a mixt. of III and the 3-nitro deriv. III is reduced in MeOH by Na-Hg to 2,5-HO(H₂N)-C₆H₃AsO₂H₂, white crystals changing color at 150° and becoming black at 200°. The further treatment is the same as for I. S. T.

A new method of preparation of quinolinic acid and some of its derivatives. EDUARD SUCHARDA. *Ber.* 58B, 1727–9(1925).—Quinolinic acid (I) is obtained in 500–50 g. yield from 500 g. 8-hydroxyquinoline under H₂O slowly treated with HNO₃ (d 1.52). The imide of I in cold NaOH with NaOCl gives 67.2% β-aminopicolinic acid, 3,2-C₆H₃(NH₂)CO₂H. The imide, m. 233°, of I is obtained in 75% yield from I and AcNH₂ at 120–5° in Ac₂O. C. A. R.

Preparation of tertiary arsines by the Friedel-Crafts reaction. A. F. HUNT AND E. E. TURNER. *J. Chem. Soc.* 127, 2667–71(1925).—PhMeAsCl (15 g.), 60 g. PhMe and 15 g. AlCl₃ give 8 g. *phenyl-p-tolylmethylarsine* (I), b₁₂ 164–5°; it has a fishy odor and slowly oxidizes on keeping; MeI gives *phenyl-p-tolyldimethylarsonium iodide*, m. 93°. PhMeEt(*p*-MeC₆H₄)AsI, m. 150° when recrystd. from EtOH and 158° when crystd. from H₂O; after crystn. from H₂O further crystn. does not change the m. p. *p*-Me-C₆H₄MgI and 20.4 g. PhMeAsCl give 18 g. (76%) of I. PhMeAsCl (15 g.) gives 7 g. (30%) of *phenylmesitylmethylarsine*, b₁₇ 164°, with a fishy odor and slowly oxidized in the air. *Phenylmesityldimethylarsonium iodide*, m. 187°. *Phenylmesitylbenzylmethylarsonium iodide*, m. 179–80°. PhMeAsCl (20 g.) and 60 g. PhBr with AlCl₃ give 5 g. *p*-bromodiphenylmethylarsine (II), b₁₈ 164° (35 g. PhBr were recovered); *p*-bromodiphenyldimethylarsonium iodide, pale yellow, m. 87°. This was also prepd. from *p*-bromophenylarsenious oxide, m. 259–61°, through *p*-bromophenylmethylidoarsine, pale yellow, m. 36.5° (70% yield from *p*-BrC₆H₄AsCl₂, MeI and NaOH in dil EtOH, followed by HCl and a little KI and satg. by SO₂); with PhMgBr this gives 60% of II. *p*-Chlorophenyldichloroarsine, b₂₂ 160°, b. 277°. *p*-Chlorophenylarsenious oxide, m. 198°. *Di-p-chlorophenylchloroarsine*, pale yellow, m. 51°. In the case of the Friedel-Crafts reaction with As compds., it is advisable to use an excess of the non-As component and to remove the HCl as fast as it is formed by gentle boiling. C. J. WEST

Tautomerism of α-aminopyridine. IV. A method of preparation of pyrimidazole and its homologs. A. D. CHICHIBABIN. *Ber.* 58B, 1704–6(1925); cf. C. A. 19, 1275. —Pyrimidazole (I) is obtained by heating α-aminopyridine (II) with BrCH₂CHO or its acetals in sealed tubes at 150–200°. If BrCH₂CH(OMe)₂ (III) is used instead of the free aldehyde, the MeOH resulting from the reaction II + III = LHBr + 2MeOH forms MeBr with the HBr and the MeBr at the high temp. of the reaction may exert a methylating action on the II so that the product will contain large amts. of methylated pyridines. α-Halogenated ketones, XCH₂COR, can theoretically yield 2 isomeric homologs of I, viz. IV and V, but in the 1 case thus far studied (ClCH₂COMe), only 1 of these isomers was obtained. I, b₂₇ 153–5°, is an oil of moldy odor, heavier than H₂O; chloroplatinate, pale orange needles with 2H₂O. Methylpyrimidazole chloroplatinate, red.

C. A. R.
